1 Introduction

On June 21, 2004, the Federal Energy Regulatory Commission (FERC) approved an Anadromous Fish Agreement and Habitat Conservation Plan (HCP) for the Rocky Reach Hydroelectric Project (Rocky Reach – FERC License No. 2145) on the Columbia River in Washington State, operated by Public Utility District No. 1 of Chelan County (Chelan PUD). The HCP provides a comprehensive and long-term adaptive management plan for meeting a No Net Impact (NNI) goal for species addressed in the plan (Plan Species) and their habitat. This document fulfills Article 10 of Appendix B and Section 9.8 of Appendix E of the FERC License issued on February 19, 2009[1], and Section 4.8 of the HCP, which requires annual reporting of progress toward achieving the NNI goal. Responsibilities toward achieving the NNI goal are described in Section 3 of the HCP, and in a 10-year Comprehensive Report assessing overall status of NNI (HCP Coordinating Committees 2013),[2] as well as successive 10-year intervals, in common understandings based upon completed studies, including those conducted as research and development for NNI progress or those not considered valid due to extenuating circumstances (Section 5.2.3 of the HCP).

The signatories of the Mid-Columbia HCPs (HCPs for the Wells, Rocky Reach, and Rock Island hydroelectric projects) meet as combined Coordinating Committees, Hatchery Committees, and Tributary Committees to expedite the process of overseeing and guiding HCP implementation. Minutes from the 2019 monthly meetings are compiled in Appendix A (HCP Coordinating Committees), Appendix B (HCP Hatchery Committees), and Appendix C (HCP Tributary Committees). In 2019, the HCP Policy Committees convened to discuss a potential impending dispute resolution from the HCP Tributary Committees, as further described in Section 3.2 and Appendix D. Appendix E lists members of the Rocky Reach HCP Committees. The Rocky Reach HCP Coordinating Committee oversaw the preparation of this 16th Annual Report, which covers the period from January 1 to December 31, 2019. (The 1st through 15th Annual Reports covered the periods January 1 to December 31, 2004, through 2018, respectively.)

[2] Public Utility District No. 1 of Chelan County – Natural Resources Department, 2013 Rock Island and Rocky Reach Anadromous Fish Agreements and Habitat Conservation Plans 2013 Comprehensive Progress Report. February 2013.

2 Progress Toward Meeting No Net Impact

The Rocky Reach HCP requires preparation of an Annual Report that describes progress toward achieving the performance standard of NNI for each Plan Species. The NNI standard consists of two components: 1) 91% combined adult and juvenile project survival, as achieved by project-improvement measures implemented within the geographic area of the project; and 2) up to 9% compensation for unavoidable project mortality provided through hatchery and tributary programs, with up to 7% compensation provided through hatchery programs and 2% through tributary programs (Section 3.1 of the HCP).

In 2019, Chelan PUD has met or exceeded all requirements for NNI under the Rocky Reach HCP for spring migrant HCP Plan Species (spring Chinook salmon [*Oncorhynchus tshawytscha*], steelhead [*O. mykiss*], sockeye salmon [*O. nerka*], and coho salmon [*O. kisutch*]). Project survival standards have been exceeded for steelhead, yearling Chinook salmon, sockeye salmon, and coho salmon; all of which are currently designated Phase III (Standards Achieved). For subyearling summer/fall Chinook salmon (a summer migrant and non-Endangered Species Act [ESA]-listed Plan Species), considerable life-history variability and limited technology constrain the ability to meaningfully estimate project survival (see Section 2.1.1). As a result, subyearling summer Chinook salmon are designated as Phase III (Additional Juvenile Studies[3]) and will continue to be compensated through the Tributary Conservation and Hatchery Compensation Plans at levels consistent with the guidance provided in the HCP. As established in Section 3.1 of the HCP, the inability to estimate survival due to limitations of technology shall not be construed as a success or a failure to achieve NNI.

Recalculated NNI production levels for all Plan Species were agreed on in 2011 within the HCP Hatchery Committees, and implementation began with the 2014 release year and will continue for the next 10 years (release years 2014 through 2023). Additionally, Chelan PUD funded the Tributary Conservation Plan's Plan Species Account at the level established in the HCP ($229,800 in 1998 dollars; see Section 2.3; Table 1).

Table 1
Rocky Reach Habitat Conservation Plan No Net Impact Progress for Plan Species (2019)

HCP Plan Species (ESA Status)	Survival Standard Met	Hatchery Compensation Provided	Tributary Conservation Plan Funded	NNI
Spring Chinook Salmon Yearlings (ESA-listed)	Yes – Combined Adult and Juvenile	Yes	Yes	Yes
Steelhead (ESA-listed)	Yes – Combined Adult and Juvenile	Yes	Yes	Yes

[3] The current phase designation will be re-evaluated in 2029.

HCP Plan Species (ESA Status)	Survival Standard Met	Hatchery Compensation Provided	Tributary Conservation Plan Funded	NNI
Sockeye (Not Listed)	Yes – Combined Adult and Juvenile	Yes	Yes	Yes
Summer/Fall Chinook Salmon (Not Listed)	Phase III (Additional Studies)	Yes	Yes	Yes – NNI compensation provided, but additional studies required
Coho Salmon (Not Listed)	Phase III (Standards Achieved)	Yes	Yes	Yes

Throughout 2019, the HCP Coordinating, Hatchery, and Tributary Committees reached agreement on numerous issues during meetings in support of achieving the NNI goals, all of which were documented in the meeting minutes or were described in stand-alone statements of agreement (SOAs). In 2019, the HCP Policy Committees also convened to discuss the potential need for a dispute resolution that arose in the HCP Tributary Committees, which resulted in developing guidance to the HCP Coordinating, Hatchery, and Tributary Committees but no formal HCP Agreements or Decisions (see Section 3.2 and Appendix D). All agreements reached among the HCP committees along with approvals for funding of habitat projects by the Rocky Reach HCP Tributary Committee, are summarized in Table 2 and discussed in the remainder of this report.

Table 2
Summary of 2019 Agreements and Decisions for Rocky Reach Habitat Conservation Plan

Date	Agreement	HCP Committee	Reference
January 14, 2019	Approved the Northern Pikeminnow Report after no disapprovals were received prior to the 30-day review deadline on January 14, 2019	Coordinating	Appendix A and Appendix M
February 13, 2019	Agreed to add analysis of linkage disequilibrium to the Hatchery M&E Plan (update to the 2017 Plan). *(Note: NMFS abstained during the January 16, 2019 meeting but approved via email on February 13.)*	Hatchery	Appendix B

Date	Agreement	HCP Committee	Reference
February 13, 2019	Agreed to the following items regarding joint meetings with the Rocky Reach and Rock Island HCP Hatchery Committees and PRCC Hatchery Sub-Committee: • Combine meeting attendance into one forum • Issue one meeting agenda (including estimated duration for discussion items) and one set of meeting minutes • Develop similar protocols for documentation and distribution of materials in emails, pending agreement to final distribution lists • Develop joint meeting protocols *(Note: NMFS abstained during the January 16, 2019 meeting but approved via email on February 13.)*	Hatchery	Appendix B
February 26, 2019	Approved the 2018 RRJFBS Report	Coordinating	Appendix A and Appendix K
March 14, 2019	Approved a General Salmon Habitat Program proposal from YN titled: *Stormy Project Area "A" Stream and Floodplain Enhancement Project*	Tributary	Appendix C
March 18, 2019	Approved the 2018 Rocky Reach HCP Annual Report after no disapprovals were received prior to the 30-day review period deadline on March 18, 2019	Coordinating	Appendix A
March 22, 2019	Approved the 2019 Broodstock Collection Protocols.	Hatchery	Appendix B and Appendix O
March 26, 2019	Approved the 2019 Rock Island and Rocky Reach HCP Action Plan *(Note: USFWS approved the plan via email on March 18, and the CCT approved the plan via a phone call to Kristi Geris on March 25, 2019)*	Coordinating	Appendix A and Appendix H
March 26, 2019	Approved the 2019 Rock Island and Rocky Reach Fish Spill Plan, as revised *(Note: USFWS approved the plan via email on March 18, and the CCT approved the plan via a phone call to Kristi Geris on March 25, 2019)*	Coordinating	Appendix A and Appendix J
March 26, 2019	Approved the 2019 RRJFBS Operations Plan, as revised *(Note: USFWS approved the plan via email on March 18, and the CCT approved the plan via a phone call to Kristi Geris on March 25, 2019)*	Coordinating	Appendix A and Appendix I
March 26, 2019	Agreed to add Emi Kondo (NMFS) to select HCP Hatchery Committees email distribution lists	Coordinating	Appendix A
April 11, 2019	Approved the updated Section 5 of the Policies and Procedures for Funding Projects document	Tributary	Appendix C
April 17, 2019	Agreed to review the current broodstock collection protocols in September and October to identify changes needed in the next Protocols and determine who will make the revisions. Topics that deserve further discussion and/or SOAs will be identified on a case-by-case basis.	Hatchery	Appendix B

Date	Agreement	HCP Committee	Reference
April 17, 2019	Agreed to distribute draft meeting materials only to a primary distribution list that includes representatives, alternates and select participants. Final materials will be sent to a broader/secondary distribution list.	Hatchery	Appendix B
May 15, 2019	Approved the revised meeting protocols and distribution lists.	Hatchery	Appendix B
May 15, 2019	Agreed not to re-activate the expired Conflict of Interest Policy SOA.	Hatchery	Appendix B
May 29, 2019	Approved the updated HCP Hatchery Committees and PRCC Hatchery Subcommittee email distribution lists, contingent on USFWS approval of the lists *(Note: USFWS approved the lists via email on May 29, 2019)*	Coordinating	Appendix A
August 27, 2019	Agreed to Chelan PUD's request to begin the 2019/2020 ladder maintenance outage at Rocky Reach Dam 2.5 weeks earlier than usual to allow more time to complete required work, contingent on approval by the YN. Rather than beginning work during the first week in January (per usual), maintenance work will begin on December 16, 2019 *(Note: the YN agreed to Chelan PUD's request via email on September 3, 2019)*	Coordinating	Appendix A
September 16, 2019	Approved the *Monitoring and Evaluation of the Chelan and Grant County PUDs Hatchery Programs 2018 Annual Report* after no disapprovals were received prior to the 30-day review period deadline.	Hatchery	Appendix B and Appendix S
September 18, 2019	Approved the *Relative Reproductive Success Study Extension Memorandum*.	Hatchery	Appendix B and Appendix W
September 18, 2019	Approved the *Broodstock Collection Protocols Development Timeline SOA*.	Hatchery	Appendix B and Appendix G
September 18, 2019	Approved Chelan PUD's *2020 Draft Monitoring and Evaluation Implementation Plan*.	Hatchery	Appendix B and Appendix Q
September 18, 2019	Agreed to describe the alternative method of equivalence testing in the narrative in the genetic monitoring objectives of the PUDs' Monitoring and Evaluation Plan (M&E Plan).	Hatchery	Appendix B
September 26, 2019	Approved the SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years*, as revised *(Note: USFWS approved the revised SOA via email on September 26, 2019)*	Coordinating	Appendix A and Appendix F

Date	Agreement	HCP Committee	Reference
October 16, 2019	Agreed to allow scientists to report the carcass survey data at the historic reach scale for comparison to past results, and also to report the data at a scale that is appropriate for each reach and population to discern distribution trends.	Hatchery	Appendix B
November 19, 2019	Approved the 2018 Northern Pikeminnow Report *(Note: WDFW approved the draft report via email on November 12, 2019)*	Coordinating	Appendix A and Appendix N
December 17, 2019	Approved the SOA, *Updated Flow Duration Curves for the Rocky Reach Project for Establishing Representative Flow Conditions*	Coordinating	Appendix A and Appendix F
December 17, 2019	Approved the 2019 Rock Island and Rocky Reach Fish Spill Report	Coordinating	Appendix A and Appendix L

The following sections summarize the achievements, actions, and activities taken in 2019 specific to project survival and dam operations, hatchery compensation, and funding of tributary habitat protection and restoration projects.

2.1 Project Survival and Dam Operations

2.1.1 Status of Phase Designations for Current Plan Species

A major feature of the Rocky Reach HCP is what is termed a "phased implementation plan" to achieve the survival standards. This approach includes three phases (Phase I, II, and III), and consists of conducting survival studies over multiple years and evaluating the achievement of survival standards, which is needed to proceed to the next phase. Progress through each phase has been described at length in previous HCP Annual Reports submitted to FERC.

Current phase designations for all Rocky Reach HCP Plan Species are summarized in Table 3.

Table 3
Current Phase Designations for Rocky Reach Habitat Conservation Plan

Plan Species	Project Survival (%)	Phase Designation	SOA Date
UCR Steelhead	94.77[1]	Phase III (Standards Achieved)	January 25, 2013
Okanogan River Sockeye Salmon	92.58[1]	Phase III (Standards Achieved)	January 25, 2013
UCR Yearling Chinook Salmon	92.28[1]	Phase III (Standards Achieved)	August 30, 2011

Plan Species	Project Survival (%)	Phase Designation	SOA Date
UCR Subyearling Summer/Fall Chinook Salmon	To Be Determined	Phase III (Additional Juvenile Studies)	September 26, 2019
Coho Salmon	92.94[2]	Phase III (Standards Achieved)	March 30, 2017

Notes:

1. Combined adult and juvenile survival achieved (HCP standard is 91%)
2. Juvenile project survival achieved using surrogacy analysis of direct-measured yearling Chinook salmon acoustic tag passage survival

Since 2013, the Rocky Reach HCP Coordinating Committee has routinely evaluated available data, study designs, and tag technology to assess the feasibility of conducting a valid survival study on subyearling Chinook salmon. These evaluations resulted in two SOAs maintaining subyearling summer Chinook salmon in Phase III (Additional Juvenile Studies) for 3 years (approved by the Rocky Reach HCP Coordinating Committee on June 25, 2013, and September 29, 2016, respectively).

In April 2019, the HCP Coordinating Committees began revisiting the feasibility of studying the survival of subyearling Chinook salmon, and subsequently convened three joint discussions of the HCP Coordinating Committees and Priest Rapids Coordinating Committee (PRCC). On May 28, 2019, Douglas PUD presented findings from the draft report, *Wells Project Subyearling Chinook Life-History Study 2011-2013*. This study found that a traditional study of a subyearling population would violate assumptions of a single- and paired-release survival model, including the inability to tag a representative sample (many of the fish are too small to handle the size and weight (burden) associated with active tags), the tag hardware disproportionately affects survival probability, not all individuals have the same probability of survival to the end of the reach, and treatment and control groups would experience unequal river and passage conditions in common reaches. On June 25, 2019, Chelan PUD presented an update of the currently available acoustic tag technology to illustrate improvements that have been made since the last review in 2016. However, this review revealed that not much has improved in terms of tag burden and limited battery life. On July 23, 2019, Dr. Rebecca Buchanan of University of Washington and Columbia Basin Research provided a presentation titled, *Considerations in the Design and Analysis of Subyearling Chinook Salmon Survival Compliance Studies – 2019*, which showed there have been no significant developments in the survival models used or ability to meet all assumptions required when employing a paired release-recapture design to estimate reach survival of subyearling Chinook salmon (i.e., a statistical solution to estimating subyearling residualization does not currently exist and therefore, effects of residualization cannot be separated from project effects). On August 27, 2019, the HCP Coordinating Committees held a subyearling studies brainstorming session to discuss the findings from 2016 and the last three joint discussions in 2019. The HCP Coordinating Committees judged that based on the information presented, conducting survival studies on subyearling Chinook salmon was not feasible at this time. On September 24, 2019, the Rock Island and Rocky Reach HCP Coordinating

Committees approved the SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years* (Appendix F). The HCP Coordinating Committees also scheduled quarterly subyearling Chinook salmon check-ins to occur during future HCP Coordinating Committees meetings occurring in February, May, August, and November each year, to continue to evaluate or monitor study design, tag technology, and life-history information on a quarterly basis to better understand the feasibility of conducting survival studies on subyearling Chinook salmon in the future.

2.1.2 Assessment of Project Survival

The Rocky Reach HCP requires that Chelan PUD shall work toward a 91% combined adult and juvenile project survival at Rocky Reach Dam, which is achieved by project-improvement measures implemented within the geographic area of the project. Progress toward this objective is described in the sections below.

2.1.2.1 Adult Passage Monitoring

When the Rocky Reach HCP was signed in 2002, it was acknowledged there was no scientifically rigorous method for the Rocky Reach HCP Coordinating Committee to assess adult project passage survival for Plan Species. Existing methods did not differentiate between mortality caused by the project and other sources of mortality (e.g., delayed mortality from injuries resulting from passage at downstream projects, injuries sustained by marine mammals, or harvest activities). Section 5.2 of the Rocky Reach HCP states that given the inability to differentiate between the sources of adult mortality, initial compliance with the combined adult and juvenile salmon and steelhead survival standard would be based on the measurement of 93% juvenile salmon and steelhead project survival or 95% juvenile salmon and steelhead dam passage survival, and an adult survival estimate of 98% to 100%.

Beginning in December 2012, Chelan PUD was able to evaluate adult passage survival through the Rocky Reach Project (dam and reservoir) for steelhead and sockeye salmon, even though unknown harvest mortality remained in the survival estimates. Passive integrated transponder (PIT)-tag detections from the PIT Tag Information System database were used to evaluate adult fish migrating upstream in 2010, 2011, and 2012 to estimate project conversion rates. For steelhead, adult fish destined for the Methow and Okanogan river systems were used for the survival evaluation. For sockeye salmon, adults returning to the Okanogan River Basin were evaluated. The 3-year arithmetic mean survival rates at Rocky Reach Project for adult steelhead and sockeye salmon were 98.93% and 98.92%, respectively (Table 4). A year prior, in 2011, Chelan PUD estimated the 3-year mean survival rates for adult spring Chinook salmon migrating through the Rocky Reach Project. This survival estimate was 99.90% for migration years 2009 through 2011. Chelan PUD will re-evaluate adult passage survival at Rocky Reach in 10-year intervals, as required per the HCP.

Juvenile, adult, and combined (juvenile and adult) survival rates at the Rock Island and Rocky Reach projects are presented in Table 4. Adult conversion rates were calculated from adult passage data for the years 2010 through 2012.[4]

The HCP combined adult and juvenile project survival standard is 91%. The HCP combined adult and juvenile project survival estimates apply to fish actively migrating through the Rock Island and Rocky Reach projects in the mainstem Columbia River and do not include mortality occurring in other locations (i.e., they do not include ocean or tributary mortality).

Table 4
Habitat Conservation Plan Juvenile, Adult, and Combined Survival Rates at Rock Island and Rocky Reach

Project	Species	Juvenile Survival	Adult Survival	Combined[5]
Rock Island	Steelhead	96.75%	99.31%[2]	96.08%
	Spring Chinook Salmon	93.75%[1]	99.89%[3]	93.65%
	Sockeye Salmon	93.27%	98.37%[2]	91.75%
Rocky Reach	Steelhead	95.79%	98.93%[2]	94.77%
	Spring Chinook Salmon	92.37%[1]	99.90%[3]	92.28%
	Sockeye Salmon	93.59%	98.92%[4]	92.58%

Notes:
1. Includes spring-migrating yearling Chinook salmon.
2. Estimate does not account for fish losses due to recreational harvest in any years.
3. No recreational harvest occurred.
4. Estimate adjusted for fish losses from recreational harvest in 2010 and 2011, but not for harvest losses in 2012.
5. Combined survival is the product of juvenile and adult survival estimates (e.g., 98% × 93% = 91%).

2.1.2.2 Valid Study Flow Duration Curve Update

Section 13.24 of the Rocky Reach HCP requires that as part of the 2013 comprehensive review, and every 10 years thereafter, the Rocky Reach HCP Coordinating Committee shall update the spring and summer period Flow Duration Curves used to define valid survival studies. The updated Flow Duration Curves must reflect "Representative Flow Conditions," meaning river flows between the 10th and 90th percentiles on the Flow Duration Curve, as calculated from the Grand Coulee Dam daily average outflow. In 2013, efforts began to update the Flow Duration Curve. The HCP Coordinating Committees agreed to develop the updated Flow Duration Curve with the historical 1929 to 1978 and 1983 to 2001 datasets used previously, to which the new 2002 to 2012 dataset was added. For comparison, Flow Duration Curves were also constructed using only the 1983 to 2012 dataset. The HCP Coordinating Committees also agreed to revise the definition of the summer period to comprise June 1 through

[4] Buchanan, R. A., and J. R. Skalski, 2012. Estimation of the Adult Salmon and Steelhead Conversion Rates through Rock Island and Rocky Reach Projects, 2010-2012. Prepared for Public Utility District No. 1 of Chelan County. December 2012.

August 15, compared to the former July 1 through August 15 period. Updated Flow Duration Curves were expected to become final in early 2014; however, in February 2014, a fracture discovered in Wanapum Dam postponed a number of efforts, including updating the curves, until time allows.

On November 19, 2019, Chelan PUD and Douglas PUD provided a joint presentation to the HCP Coordinating Committees, which addressed the questions asked by the HCP Coordinating Committees in 2013. The presentation also described approaches to updating the curves, including: 1) switching from the Grand Coulee flow duration curves to project-specific curves for the Wells, Rocky Reach, and Rock Island projects; 2) using a rolling average of the most recent 30 years to calculate the curves, such that 10 years from now, 10 years of new data will be added to the dataset and the older 10 years of data will be removed; and 3) including the month of June in the summer flow duration curves. After discussing these proposed updates at length, notably about whether the proposed time frames were representative of Plan Species run-timing and normal river flow conditions, on December 17, 2019, the Rocky Reach HCP Coordinating Committee approved the SOA, *Updated Flow Duration Curves for the Rocky Reach Project for Establishing Representative Flow Conditions* (Appendix F), which included all three proposed approaches to updating the curves.

2.1.2.3 2019 Survival Studies

No survival studies were conducted at the Rocky Reach Project in 2019.

In 2020, the Rocky Reach HCP Coordinating Committee will continue evaluating the feasibility of studying subyearling summer Chinook salmon survival, as stipulated in the SOA maintaining subyearling summer Chinook salmon in Phase III (Additional Juvenile Studies) for another 3 years (through September 2022), as approved on September 26, 2019 (see Section 2.1.1). The Rocky Reach HCP Coordinating Committee will also continue planning for the upcoming 2021 Survival Verification Study.

2.1.3 Project Operations and Improvements

This section summarizes project operations and progress toward maintaining the juvenile project survival standard at Rocky Reach Dam in 2019. Actions in 2019 were guided by the *2019 Rocky Reach and Rock Island HCP Action Plan* (Appendix H), as approved by the Rocky Reach and Rock Island HCP Coordinating Committees on March 26, 2019 (Appendix A).

2.1.3.1 Operations

2.1.3.1.1 *Juvenile Bypass System and Fish Spill Operations*[5]

At Rocky Reach Dam, juvenile fish spill operations are guided by two documents. The Rocky Reach and Rock Island HCP Coordinating Committees approved both the *2019 Rocky Reach Juvenile Fish*

---

[5] 129 FERC ¶ 62,183 (issued December 8, 2009). Order Modifying and Approving Operations Plan Pursuant to License Article 402.

Bypass System Operations Plan (Appendix I) and the *2019 Rocky Reach and Rock Island Fish Spill Plan* (Appendix J) on March 26, 2019. The Rocky Reach Juvenile Fish Bypass System (RRJFBS) operated continuously from April 1 through August 31, 2019, which covered the normal bypass operating period for the outmigration of juvenile salmon and steelhead at Rocky Reach Dam.

The *2018 Rocky Reach Juvenile Fish Bypass System Report* (Appendix K), which summarizes activities at the RRJFBS in 2018, was approved by the Rocky Reach HCP Coordinating Committee on February 26, 2019.

Spill for summer-migrating subyearling Chinook salmon at Rocky Reach Dam began on June 2, 2019, at 0001 hours, and continued uninterrupted for 72 days through 2400 hours on August 12, 2019. The target spill level for the duration of the summer spill period in 2019 was 9% of the estimated daily average river flow, as specified and approved in the *Rocky Reach Fish Spill Plan* (Appendix J). Spill volume for the 72-day summer period averaged 9.09% of the total river flow and comprised 9.02% fish spill and an additional 0.07% unavoidable hydraulic spill. The Columbia River flow rate past Rocky Reach Dam during the spill period averaged 100,417 cubic feet per second (cfs), and the daily average spill rate was 9,131 cfs. Following completion of the bypass operations on August 31, 2019, it was estimated that spill was provided for 99.1% of the subyearling Chinook salmon outmigration passing Rocky Reach Dam.

Complete Rocky Reach Dam 2019 fish spill operations results are summarized in the *2019 Rocky Reach and Rock Island Fish Spill Report* (Appendix L), which was approved by the Rocky Reach and Rock Island HCP Coordinating Committees on December 17, 2019.

2.1.3.1.2 *Rocky Reach Dam Large Unit Repair*

In 2013, Rocky Reach Dam Turbine Units C8, C9, C10, and C11 were modified from their normal Kaplan configuration to a temporary, fixed blade configuration as an interim measure while permanent repairs are fabricated and installed on these four large units (see Section 2.1.3.2.1). An interim operating angle of 31 degrees was selected because it is the most hydraulically efficient angle at full turbine discharge of 23,000 cfs. The 31-degree angle is the safest angle for fish passage (due to it being hydraulically efficient), and it represents the safest position of the blades because at this angle cavitation is minimized and the risk of a turbine runaway is lowest. In 2019, due to delays in recommissioning Turbine Unit C1 (see Section 2.1.3.2.3) and outages of Units C2 and C3, the recommissioning of Turbine Unit C9 was postponed from fall 2019 to February 2020. Maintenance continues on the large units, with a target completion date of first quarter 2023.

2.1.3.1.3 *Rocky Reach Dam Turbine Unit C1 Outage*

In January 2018, Rocky Reach Dam Turbine Unit C1 was taken offline to investigate an oil leak and mechanics discovered a loss of oil from the unit hub via the trunnion seals. Turbine Unit C1 remained offline for the remainder of 2018 while Rocky Reach Dam mechanics worked on repairing the unit (see Section 2.1.3.2.3).

In 2019, Chelan PUD mechanics and engineering staffs attempted multiple solutions to resolve trunnion seal leaks, with the unit ultimately disassembled to replace the trunnion bushings. Due to concurrent maintenance activities at the powerhouse and delayed receipt of parts necessary for the bushing repair, the return-to-service date for Turbine Unit C1 was postponed from August 2019 to January 2020 (note: as of January 2020, the return-to-service date is March 2020).

2.1.3.1.4 *Rocky Reach Dam Surface Collector and Turbine Unit C2 Altered Operations*

In February 2018, in preparation for operating without Rocky Reach Dam Turbine Unit C1 online at the start of the juvenile bypass system operations on April 1 (see Section 2.1.3.1.1), the Rocky Reach HCP Coordinating Committee approved an Operating Plan for the Rocky Reach Dam Surface Collector and Turbine Unit C2 during the Turbine Unit C1 outage. The key changes from normal operations include: 1) using three additional RRJFBS Surface Collector pumps to increase attraction flow from 6,000 to 6,660 cfs into the RRJFBS Surface Collector entrances (3,330 cfs for each entrance); and 2) increasing Unit C2 flow from its normal soft-limit set-point of 12.2 thousand cubic feet per second (kcfs) to a soft-limit flow of 15.2 kcfs.

In 2019, Rocky Reach Dam Turbine Unit C1 was still not operational at the start of the juvenile bypass season on April 1; therefore, the same altered operations implemented during the 2018 juvenile bypass season were implemented during the 2019 juvenile bypass season. The Rocky Reach HCP Coordinating Committee-approved altered operations were appended to the *2019 Rocky Reach Juvenile Fish Bypass System Operations Plan* (Appendix I). These altered operations are also the same as those implemented in June 2014 through the end of the 2014 fish bypass season, when Unit C1 was taken offline to repair a crack in the rotor.

2.1.3.1.5 *Rocky Reach Dam Turbine Unit C2 Outage*

In October 2019, Rocky Reach Dam Turbine Unit C2 was taken offline due to a possible failure of the internal servo rod seal. However, due to concurrent maintenance activities, mechanics were unable to investigate this issue and Turbine Unit C2 remained offline for the remainder of 2019 (see Section 2.1.3.2.5).

2.1.3.1.6 *Rocky Reach Dam Turbine Unit C3 Outage*

In February 2019, Rocky Reach Dam Turbine Unit C3 was taken offline due to leaking trunnion seals. The Rocky Reach HCP Coordinating Committee discussed changes in attraction flow in the cul-de-sac area of the Rocky Reach Dam forebay with both Turbine Units C1 and C3 offline and potential impacts to juvenile and adult yearling Chinook salmon survival performance at Rocky Reach Dam. The Rocky Reach HCP Coordinating Committee reviewed an analysis conducted by Drs. John Skalski and Richard Townsend (Columbia Basin Research) that reviewed juvenile survival data under three scenarios. The purpose of the analysis was to demonstrate how reallocating juvenile yearling Chinook salmon passage and route specific survival from the surface collector and the juvenile intake screens to turbine passage routes might translate into changes in juvenile project survival estimates and the 91% combined juvenile/adult survival metric for Plan Species outlined in the Rocky Reach HCP. This analysis found a slight reduction in collection efficiency, but the project would still meet the survival standard for Plan Species.

Rocky Reach Dam Turbine Unit C3 was repaired and returned to service on September 6, 2019. However, in October 2019, Turbine Unit C3 was taken back out of service to investigate small traces of oil in the tailrace, which ultimately was determined to be caused by Turbine Unit C2 (see Section 2.1.3.2.5). Due to concurrent maintenance and repair activities, Turbine Unit C3 was not returned to service until November 18, 2019. In December 2019, Turbine Unit C3 was taken offline again for an inspection and had not yet been returned to service by the end of 2019 (see Section 2.1.3.2.4).

2.1.3.1.7 *Juvenile Fish Bypass System Pre-Season Marked Fish Releases*

The RRJFBS is used for monitoring the physical condition of fish and species composition. Chelan PUD also uses the facility to evaluate seasonal run-timing for target species. Each year, Chelan PUD conducts pre-season marked fish releases at the RRJFBS to test the system for possible descaling, injury, or mortalities prior to the start of the bypass season, which begins on April 1 at 0000. Test fish are fin-clipped to differentiate between release locations, released into the system, recovered at the sampling facility, are visually inspected, and the results are tallied.

On March 21, 2019, Chelan PUD conducted 2019 pre-season marked fish releases in the RRJFBS and juvenile intake screen system deployed in Rocky Reach Dam Turbine Unit C2. The releases were conducted under the altered operations that were approved by the Rocky Reach HCP Coordinating Committee in 2018 (see Section 2.1.3.1.4). A total of 100 and 100 fish were released in the north and south entrances, respectively; and 99 and 98 fish were recovered, respectively. A release of marked fish into Unit C2 was conducted at a higher velocity and 42 of 100 fish were recovered. Due to low recovery numbers, divers were deployed to inspect the Unit C2 juvenile intake screen and adjusted the screen deployment. A second release into Unit C2 occurred on March 26, 2019, and 96 of 99 fish were recovered. No signs of descaling or injury were observed during any of the releases. A complete report summarizing 2019 activities at the RRJFBS is expected in 2020.

2.1.3.1.8 *Pikeminnow Predator Control*

Chelan PUD has implemented a northern pikeminnow (*Ptychocheilus oregonensis*) predator-control program in the Rocky Reach Project since 1994. Since 1996, the Chelan PUD has contracted annually with the U.S. Department of Agriculture (USDA) to carry out this program. Chelan PUD also provides funding for the annual Pikeminnow Derby sponsored by the East Wenatchee Rotary Club.

Complete results from the 2017 removal effort were summarized in the *2017 Rock Island HCP Annual Report* and are described in the *2017 Rock Island and Rocky Reach Pikeminnow Control Program Summary Report* (Appendix M), which was approved by the Rock Island and Rocky Reach HCP Coordinating Committees on January 14, 2019. Complete results from the 2018 removal effort were summarized in the *2018 Rock Island HCP Annual Report* and are described in the *2018 Rock Island and Rocky Reach Pikeminnow Control Program Summary Report* (Appendix N), which was approved by the Rock Island and Rocky Reach HCP Coordinating Committees on November 19, 2019.

In 2019, Chelan PUD continued implementing the northern pikeminnow removal program with Columbia Research long-line angling during the pre-migration period to target large pikeminnow that stage in deep reservoir areas and are difficult to capture with other gear types. The 2019 USDA hook-and-line angling program commenced during the peak of the juvenile salmonid migration. The total combined harvest of pikeminnow in 2019 from Rocky Reach and Rock Island reservoirs was 76,247 fish. Harvest numbers from the various control efforts in 2019 were as follows: USDA hook-and-line angling, 47,967 fish; Columbia Research long-line angling, 24,930 fish; East Wenatchee Rotary Club Pikeminnow Derby, 2,028 fish; and removal by Chelan PUD Fish and Wildlife personnel, 1,322 fish. A report summarizing results of the 2019 removal effort is expected sometime in early 2020.

2.1.3.2 Improvements and Maintenance

Facility improvements and maintenance at the Rocky Reach Project in 2019 that had the potential to affect Plan Species are described in this section.

2.1.3.2.1 *Rocky Reach Dam Large Unit Repair*

In 2013, while repairing internal hydraulic issues in Rocky Reach Dam Turbine Unit C10, mechanic crews discovered a deep hairline crack in a stainless steel rod that delivers oil to the servo motor. Rocky Reach Dam Turbine Units C8, C9, and C11 all have the same stainless steel rod design as part of the servo motors. During the 2013/2014 winter maintenance outage, interim fixes were installed on Units C8, C9, C10, and C11 (see Section 2.1.3.1.2). In 2015, permanent fixes were initiated on Turbine Unit C10. Repairs were anticipated to require 6 months per unit and were projected to be completed by 2019, pending any additional unforeseen delays. In 2016, head-cover issues were identified in Unit C8, and cracks were identified in the wheels of the bridge crane required to hoist the turbines for repair. In December 2017, Turbine Unit C8 was repaired and returned to service in February 2018. In 2019, due to delays in recommissioning Turbine Unit C1 (see Section 2.1.3.2.3), the return-to-service date for Turbine Unit C9 was postponed from fall 2019 to February 2020. These unexpected issues, as well as unexpected outages and delays with Turbine Units C1, C2, and C3, postponed the projected completion date of the large unit repairs to first quarter 2023. The priority for the remaining large unit repairs, from highest to lowest, is Unit C9, Unit C10, and finally Unit C11.

2.1.3.2.2 *2018/2019 Rocky Reach Adult Fish Ladder Winter Maintenance*

The upper adult fishway at Rocky Reach Dam was taken offline for annual winter maintenance on January 2, 2019, and the lower adult fishway was taken offline on January 8, 2019. The entire adult fish ladder was returned to service on February 15, 2019. Activities beyond general maintenance included: 1) diffuser inspection; 2) attraction water pump inspection C; and 3) traveling water screen inspection.

In 2018, the HCP Hatchery Committees approved a request from Washington Department of Fish and Wildlife (WDFW) to lethally remove hatchery-origin *O. mykiss* between 12 and 18 inches in length that are encountered during fish rescues associated with fishway maintenance outages at Chelan PUD and Douglas PUD hydroelectric projects. The purpose of this request was to address concerns about hatchery steelhead remaining in the river as resident trout. During the 2018/2019 winter maintenance outage at Rocky Reach Dam, initially, 12- to 18-inch *O. mykiss* collected during fish salvage activities that did not have a coded wire tag were released. It was later clarified that WDFW is interested in removing all 12- to 18-inch *O. mykiss* regardless of tag presence. This was communicated to Chelan PUD staff who turned over to WDFW the remaining 12- to 18-inch *O. mykiss* collected during fish salvage activities at Rocky Reach Dam so WDFW could examine the fish to determine the source of the fish.

Following the fish rescues associated with the 2018/2019 winter maintenance outage, WDFW also expressed interest in collecting any unique species encountered during the fish rescues to determine the source. Chelan PUD and WDFW will coordinate, as needed, prior to conducting fish rescues at Rocky Reach Dam in future years.

2.1.3.2.3 *Rocky Reach Dam Turbine Unit C1 Repair*

In January 2018, Rocky Reach Dam Turbine Unit C1 was taken offline to investigate an oil leak (see Section 2.1.3.1.3). Mechanics discovered a loss of oil from the unit hub via the trunnion seals. New replacement stock trunnion seals were received, installed, and tested; however, the new stock seals failed to stop oil from leaking from the unit hub. Chelan PUD investigated hydraulically locking the blades into place; however, engineers were not confident that operating in a hydraulically locked configuration would not result in an oil leak with a failed trunnion seal. In May 2018, Chelan PUD Board of Commissioners approved entering into a sole-source contract to design and manufacture engineered trunnion seals for Turbine Unit C1 at Rocky Reach Dam. The engineered trunnion seals were installed and tested; however, failed to stop oil from leaking from the unit hub. This led Rocky Reach Dam mechanics to believe the issue may be leaky trunnion seals due to trunnion bushing wear.

In 2019, disassembly of Turbine Unit C1 began to replace the trunnion bushing. Delays were caused by a shortage of headgates, which were being used for other maintenance activities. By May 2019, Turbine Unit C1 was completely disassembled but repairs were postponed due to delayed delivery of necessary components for repair from the vendors. As of the end of December 2019, Rocky Reach Dam mechanics were still waiting to receive the wicket gate servo control unit from the vendor. As of December 2019, the estimated return to service date for Turbine Unit C1 is March 2020.

2.1.3.2.4 *Rocky Reach Dam Turbine Unit C3 Repair*

On February 19, 2019, Rocky Reach Dam Turbine Unit C3 was taken offline for an inspection and mechanics discovered more than 5 gallons of water inside the hub (see Section 2.1.3.1.6). The engineered seals designed for Rocky Reach Dam Turbine Unit C1 were installed in Turbine Unit C3, the unit was pressurized, and the seals did not work. Mechanics implemented the same evaluation process as was done for Turbine Unit C1, including considering hydraulically locking the blades into place, manufacturing new trunnion seals, and possibly using a compound that is injected into the hub to improve the seal and allow the blades to operate in a Kaplan configuration. In June 2019, the new engineered Chesterton seals for Turbine Unit C3 were received and underwent testing to determine if the seals performed as designed. Another new set of trunnion seals were also ordered. On July 17, 2019, Turbine Unit C3 was returned to service with the Chesterton seals installed. On August 26, 2019, Turbine Unit C3 was removed from service and inspected. Two blade seals had minimal oil leaks, but upon draining the oil from the turbine hub, only a very small and acceptable amount of water was found in the turbine hub. The second set of new trunnion seals were installed and tested, and no leakage was observed. Therefore, Turbine Unit C3 was returned to service on September 6, 2019, operating with the second set of new trunnion seals. Mechanical staff continued obtaining daily oil level readings on the unit and if the levels are off, the unit would be taken offline to inspect and test the integrity of the seals. In December 2019, the unit was taken offline for inspection. Results are expected in early 2020.

2.1.3.2.5 *Rocky Reach Dam Turbine Unit C2 Repair*

In October 2019, Rocky Reach Dam Turbine Unit C2 was taken offline to investigate small traces of oil observed in the tailrace. The issue is possibly a failure of the internal servo rod seal causing over-pressurization of the turbine hub (see Section 2.1.3.1.5); however, mechanics have not yet been able to get into Turbine Unit C2 to investigate the issue because crews and equipment (headgates) were addressing Turbine Units C1 (repairs), C3 (seals), C7 (vibration issues), and C9 (repairs). Turbine Units C1 to C7, are designed with the same internal servo rod seals and trunnion seals. In 2020, Chelan PUD mechanics plan to assess these parts across the entire range of small units.

2.1.3.2.6 *Tumwater Dam Fishway Maintenance*

In September 2018, a snorkeling survey at the Tumwater Dam fishway identified erosion at the end of the fishway. In December 2018, a private contractor began drilling core samples within the footprint of the fishway to inform a scope for possible additional work involving installation of pin piles.

In early February 2019, the contractor completed the exploratory drilling and learned two things: 1) the bottom layer of concrete below the fishway was not as thick as depicted on the design drawings such that using pin piles to address the erosion would not be effective; and 2) the extent of erosion was much less than first speculated. Therefore, Chelan PUD engineers determined repairs are not needed at this time. Chelan PUD amended the Tumwater Dam Operations Plan to include further evaluation of these conditions during low water events.

2.1.3.2.7 *2019/2020 Rocky Reach Adult Fish Ladder Winter Maintenance*

On August 27, 2019, the Rocky Reach HCP Coordinating Committee agreed to Chelan PUD's request to begin the 2019/2020 ladder maintenance outage at Rocky Reach Dam 2.5 weeks earlier than usual to allow more time to complete the required work. This includes the recommissioning of Turbine Units C1 and C9, improvements to the fish viewing windows, and completing the preventative, routine maintenance. On December 16, 2019, the adult fish ladder at Rocky Reach Dam was taken offline for annual winter maintenance. The ladder should be back to service by mid-February 2020.

A fish rescue was performed in the upper portion of the adult fish ladder on December 16, 2019, and in the lower portion of the adult fish ladder on January 9, 2020, prior to maintenance activities in the respective areas.

2.2 Hatchery Compensation

Section 8.1 of the Rocky Reach HCP describes a Hatchery Compensation Plan with two primary objectives: 1) to provide compensation for Plan Species; and 2) to implement specific elements of the hatchery program consistent with the overall objectives of rebuilding natural populations and achieving NNI. In 2019, Chelan PUD continued to provide funding and capacity for hatchery production consistent with meeting NNI. Recalculated hatchery production values required to meet NNI through release year 2023 were approved by the Rocky Reach HCP Hatchery Committee on December 14, 2011, and represented in *Chelan PUD's No Net Impact and Inundation Obligations for Release Years 2014-2023*. Hatchery compensation for the Rocky Reach Project in 2019 included the release of 2,561,498 juvenile salmonids (combined Rocky Reach and Rock Island hatchery compensation; Table 5).

In June 2015, the HCP Hatchery Committees agreed to convene joint sessions of the HCP Hatchery Committees and PRCC Hatchery Sub-Committee when discussing agenda items applicable to and requiring participation from both committees. These practices benefit the HCP Hatchery Committees through increased coordination and sharing of expertise. The Grant PUD representatives have no voting authority under the HCPs; however, because these joint discussions influence similar and sometimes overlapping hatchery programs, those discussions are documented and included here, accordingly. The HCP Hatchery Committees and PRCC Hatchery Sub-Committee continued holding joint sections of meetings in 2019 when agenda items pertained to both sets of committees. In May 2019, the HCP Hatchery Committees and PRCC Hatchery Subcommittee agreed to a common set of meeting protocols, shared support and facilitation staff, and a single set of email lists for distributing meeting materials to further improve efficiency among committees (discussions are summarized in Section 2.2.2.10). This coordination and joint process will continue in 2020.

2.2.1 Hatchery Production Summary

Table 5 summarizes and compares HCP hatchery production objectives and actual 2019 smolt releases.

Table 5
2019 Production Level Objectives and Smolt Releases for Rocky Reach Habitat Conservation Plan Hatchery Programs

Species[a]	Program	Final Rearing Site	Rocky Reach Production Level Objectives (2014 to 2023)[b]	Total Releases for Rocky Reach in 2018 (Number of Fish)
Spring Chinook Salmon	Methow	Chewuch Acclimation Facility	60,516	72,000 smolts
Summer Chinook Salmon	Chelan Falls	Chelan Falls Acclimation Facility	576,000	528,567 smolts
Steelhead	Wenatchee	Chiwawa Acclimation Facility	247,300[c]	216,666 smolts
Sockeye Salmon	Okanogan	kł cp̓əlk̓ stim̓ Hatchery	591,050[d] (34% of kł cp̓əlk̓ stim̓ Hatchery production)	1,564,000 fry
Spring Chinook Salmon	Okanogan	Chief Joseph Hatchery	115,000 (12.81% of Chief Joseph Hatchery production)	62,403 smolts
Summer Chinook Salmon	Okanogan	Chief Joseph Hatchery /Omak Pond	94,570 (13.51% of Chief Joseph Hatchery production	0 subyearlings[e]
Summer Chinook Salmon	Okanogan	Similkameen Acclimation Facility	166,569 (12.81% of Chief Joseph Hatchery production)	117,862 yearlings

Notes:

a. Coho salmon mitigation met by the funding agreement with the YN.
b. As specified in the Rocky Reach and Rock Island HCP Hatchery Committees SOA Chelan PUD Hatchery Compensation, Release Years 2014 to 2023, approved December 14, 2011.
c. Steelhead production at Chiwawa Acclimation Facility includes Rock Island and Rocky Reach obligations.
d. Combined with the Rock Island HCP, the Okanogan sockeye salmon production requirement totals 591,050 smolts (production is allocated between the two HCPs); the table includes the number of fry released. By agreement of the HCP Hatchery Committees, this production requirement is satisfied for Okanogan sockeye salmon by funding of the Okanagan Skaha Lake sockeye salmon reintroduction program until otherwise determined by the HCP Hatchery Committees.
e. Due to low egg take for brood year 2018, there was not a subyearling release.

2.2.2 *Hatchery Planning and Implementation*

This section details the actions taken in 2019 that are relevant to planning for hatchery operations that support the HCP.

2.2.2.1 2019 Broodstock Collection Protocols

In February 2019, the HCP Hatchery Committees began their review of the draft 2019 Broodstock Collection Protocols for Chinook salmon and steelhead. The revised draft protocols were approved via email as follows: WDFW, Chelan PUD, Douglas PUD, National Marine Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USFWS), the Colville Confederated Tribes (CCT), and the Yakama Nation (YN) approved on March 22, 2019. The final 2019 Broodstock Collection Protocols (Appendix O) were distributed to the HCP Hatchery Committees on March 28, 2019, and implemented at program hatcheries throughout 2019. As in previous years, the 2019 Broodstock Collection Protocols guide the collection of salmon and steelhead broodstock in the Methow River, Wenatchee River, Chelan River, and Columbia River. The protocols are consistent with previously defined program objectives such as program operational intent (i.e., conservation and/or harvest augmentation) and mitigation production levels (i.e., HCPs), and they comply with ESA permit provisions.

2.2.2.1.1 *Broodstock Collection Protocols Development Timeline*

During the development of the 2019 Broodstock Collection Protocols in early 2019, several major topics were raised but not fully discussed in time for inclusion in the document. It was noted that the broodstock collection protocols are intended to be a living document that can be amended in-season; however, it was also noted that topics that require major consideration by the HCP Hatchery Committees should be discussed prior to drafting the Protocols each year. In addition, the Protocols are not the correct place for documenting programmatic changes that would be better documented in SOAs or HCP Decisions. In August 2019, the HCP Hatchery Committees and PRCC Hatchery Sub-Committee jointly agreed to amend the existing Broodstock Collection Protocols Development Timeline SOA to accommodate earlier discussion and editing of the Protocols related to programmatic changes that are not dependent on run-size in advance of the initial annual draft Protocols for review. The Committees also noted that authorship should be shared among permit holders, which includes WDFW and the PUDs, whereas in the past the protocols were largely developed by WDFW. A list of Broodstock Collection Protocols Discussion Topics for 2020 was developed with associated lead representatives and meeting dates to be discussed (Appendix P). In September, the HCP Hatchery Committees and PRCC Hatchery Sub-Committees approved the amended *Broodstock Collections Protocols SOA* outlining a revised timeline for early document development, commencing in the fall prior to a given year's Protocols.

2.2.2.1.2 *Alternative Broodstock Composition and Mating Strategies*

During the development of the 2019 Broodstock Collection Protocols in early 2019, the consequences of potentially including jacks (age-3 fish) in broodstock was raised as a topic that should be researched further, especially considering there could be low numbers of age-4 and older fish available for broodstock collection in 2019. Douglas PUD developed a literature review to address the question and found a body of work on alternative methods for broodstock mating regimes that should also be considered by the HCP Hatchery Committees. Douglas PUD provided their findings to the HCP Hatchery Committees in a presentation in September and accompanying white paper in October entitled "*Review of Hatchery Broodstock and Mating Practices for Conservation Programs*" (Appendix B).

The purpose of conservation programs is to conserve and rebuild populations, minimize negative ecological impacts, conserve diversity, and minimize negative genetic impacts. However, ideal conditions are rarely met, and artificial selection is inevitable in hatchery propagation and due to selectivity of fisheries.

A large body of literature on incorporation of jacks into broodstock and strategies for broodstock management were reviewed. Methods for calculation of a jack incorporation rate were proposed. Two general methods for broodstock management were reviewed. The first method, termed the "genetically benign" approach, seeks to minimize genetic drift and domestication, incorporate wild fish into the broodstock, and randomize broodstock selection and spawning to minimize artificial selection. The second method, termed the "emulating natural processes" approach, seeks to actively counteract artificial selection and emulate the mate choice that occurs in nature. It was suggested to modify the current mating approach by including jacks at a predetermined rate based on natural occurrence and contributions to spawning, and to pair mates based on size. The Committees discussed the challenges to introducing new methods such as ensuring that the mate selection was feasible during actual spawning processes and what effects could be measured to evaluate the success of the modified approaches. Douglas PUD suggested implementing some elements of the new approaches in the Methow Fish Hatchery program in 2020 to test the feasibility in the field, and to inform hatchery managers of the desire to improve practices. Discussions will continue in 2020 as methods are developed for inclusion in the 2020 Broodstock Collection Protocols.

2.2.2.1.3 *Establishing Ranges Around Broodstock Collection Targets*

During the development of the 2019 Broodstock Collection Protocols in 2019, the idea of providing ranges around broodstock collection targets rather than a single numerical target was proposed; however, a method for determining the ranges had not been agreed upon. In October, Douglas PUD gave a presentation entitled "*Managing Risk and Expectations in Broodstock Collection*" that outlined an approach for modeling production targets using basic broodstock calculation that includes several factors such as pre-spawn survival and fecundity. Each of those factors has a mean and associated variance that are calculated from annual datasets, and a random draw from the distribution of each factor is unlikely to give the mean value of the distribution. In other words, if variances around the mean for a factor like fecundity are large, choosing an individual with much less than or much greater than the mean fecundity is more likely. Histograms can be used to depict the distributions of various factors, or alternatively, one can ask the model to identify a number of females by choosing a number of model iterations to test allowable critical levels of females necessary to achieve the target number of smolts while staying below 110% of the production target. By comparing the number of females against the probability of meeting a target and exceeding permitted production levels, one can identify an optimum number of females, or a range around the optimum, to hold for broodstock.

It was suggested that the updated modeled approach be compared with the current calculation method for determining broodstock targets. It was concluded that while the original intent of the method was to provide a range around broodstock targets in broodstock collection protocols, it may be disadvantageous to provide a range to the fish culturists, who will tend to collect the maximum if given a range rather than a single number. The utility of the method is to identify the factors driving the selection for the number of females in a given year (e.g., fecundity) and to be able to make in-season adjustments with greater confidence.

Douglas PUD suggested preparing a white paper with WDFW to use the method across programs coupled with a proposal to implement the method with one of the programs in the 2020 Broodstock Collection Protocols.

2.2.2.1.4 *Differentiating Natural-Origin Okanogan River Spring Chinook Salmon from Natural-Origin Methow Basin Spring Chinook Salmon*

During the development of the 2019 Broodstock Collection Protocols, it was determined that a method for differentiating natural-origin Okanogan River spring Chinook salmon during the collection of Methow Fish Hatchery broodstock at Wells Dam will be needed beginning in 2021, the first year that 4-year-old fish originating from the new Okanogan program would return over Wells Dam. The CCT would like to prevent fish from the Okanogan River from becoming incidentally collected for Methow Fish Hatchery broodstock at Wells Dam, though some would be able to ascend Wells Dam if trapping is not in operation every day at both ladders. A proposed method may also include a retrospective analysis to determine the prevalence of Methow Basin fish in Okanogan program broodstock. Possible methods for differentiating between the two stocks were discussed, focusing specifically on the use of elemental signature analysis on scales or fin-rays in an expedient manner while holding broodstock. A need was identified to begin collecting scales from wild yearling smolts known to originate from the Okanogan Basin during PIT-tagging or snorkel surveys to establish a baseline for the elemental signature of the Okanogan River compared to the Methow River. Similar analyses were done in the Wenatchee Basin; however, life-history variation that caused fish to move between waterbodies created confounding results. It was not known whether elemental signatures laid down into scales or fin rays of juvenile fish would still be present in adult fish 4 and 5 years later. Discussions on the use of elemental signature analysis to differentiate the two stocks will continue in 2019, with a plan to be proposed by the CCT.

2.2.2.1.5 *Surplus Broodstock Collection and Eggs*

2.2.2.1.5.1 Wenatchee River Steelhead and Salmon

In past years, broodstock collection protocols were written to ensure broodstock were collected throughout the return year. In 2019, run forecasts to the Wenatchee Basin were low and it was suggested that opportunities to collect broodstock be maximized by collecting on all days and at all sites available, and a high proportion of early returning fish be retained in a manner that would not be normally advocated but would be a prudent action to avoid under-collecting later in the season. The 2019 Broodstock Collection Protocols were revised to state that, in the Wenatchee Basin, trapping at Dryden Dam Traps and Tumwater Dam could be carried out simultaneously for summer Chinook salmon, summer steelhead, and coho salmon.

2.2.2.1.5.2 Chelan Falls Summer Chinook

In the 2019 Broodstock Collection Protocols, the Wells Dam Volunteer Trap and instream collection via temporary picket weir and beach seining in the Chelan River Habitat Channel were identified as sources for summer Chinook salmon brood used in the Chelan Falls summer Chinook salmon program. Due to safety concerns, the Chelan River Canal Trap previously used to collect broodstock was deemed infeasible to operate without major modifications. The Committees discussed the desire to coordinate the timing of trapping in the Chelan River with collection at the Wells Dam Volunteer Trap. It was also noted that the long-term objective is to collect broodstock for the Chelan Falls program from within the Chelan River, and that collection at Wells Dam is considered a short-term back-stop as collection at sites in the Chelan River is piloted. In 2020, Chelan PUD will present results from the pilot broodstock collection efforts in the Chelan River.

2.2.2.1.5.3 Excess of Methow Spring Chinook Salmon Eggs

In October 2019, it was reported that Methow Fish Hatchery had approximately 8,000 spring Chinook salmon eyed eggs in excess of 110% of program targets due to high fecundities. The eggs were the progeny of hatchery-origin females crossed with wild males; however, the males were crossed with other females whose eggs would be retained so their genes would not be lost from the overall population. The Wells and RR Hatchery Committees discussed whether the eggs could be transferred to the Winthrop National Fish Hatchery (WNFH) and whether eggs from WNFH could be transferred to the CCT's 10j Program at Chief Joseph Hatchery, consistent with the permit that would not allow transfer directly from Methow Fish Hatchery. It was determined that WNFH and the 10j program were at capacity and could not receive the eggs; therefore, the eggs were destroyed to conform to the ESA permit conditions.

2.2.2.2 2019 Rearing and Release Strategies

2.2.2.2.1 *Wenatchee Steelhead Release Plan 2018-2020*

In February 2018, Chelan PUD presented to the HCP Hatchery Committees a Draft 2018-2020 Steelhead Release Plan (Appendix B). The permit for the Wenatchee steelhead programs includes a special condition to minimize residualism and maximize downstream survival, so Chelan PUD and WDFW drafted a three-year release plan with the following objectives: evaluate survival based on size at release to optimize hatchery practices, evaluate rearing vessels, minimize confounding variables, and use data to assess monitoring and evaluation (M&E) objectives. The HCP Hatchery Committees discussed previous release plans, concerns about stray rates, and survival metrics. Analysis for the program included a PIT-tag study and size evaluation. Because NMFS does not provide direction on how to measure residualism and survival to determine baseline conditions for the Wenatchee programs, the HCP Hatchery Committees are responsible for agreeing on a methodology for meeting this permit condition. The HCP Hatchery Committees provided feedback to Chelan PUD and WDFW on release location, tag burden, and study design. In March 2018 the HCP Hatchery Committees approved the *Wenatchee Steelhead Release Plan (Brood Years 2017 to 2019)* as follows: Chelan PUD, WDFW, USFWS, NMFS, YN, and CCT approved on March 12, 2018. The plan is a three-year study beginning with the 2018 release year (brood year [BY] 2017).

As part of the 3-year release plan, Chelan PUD prepared a PIT-tagging study to evaluate residualism in early 2018 (described below). In order to reduce the number of co-variates and PIT tag enough steelhead to evaluate residualism, Chelan PUD requested approval to not transfer a proportion of the steelhead overwintered at Chiwawa Acclimation Facility to Blackbird Pond for final acclimation in January 2018, before the final plan was developed. The HCP Hatchery Committees discussed the draft plan and the proposed transfer and approved Chelan PUD's request to move approximately 25,000 hatchery-by-hatchery steelhead, destined for final acclimation at Blackbird Pond, from the enzyme-linked immunosorbent assay (ELISA) pond to Raceway 2 at the Chiwawa Acclimation Facility and forego final acclimation at Blackbird Pond in 2018.

2.2.2.2.1.1 Establishing Baseline Conditions in the Wenatchee Steelhead Program

The Wenatchee steelhead permit also requires Chelan PUD and WDFW to minimize residualism and maximize downstream migration of steelhead. Because NMFS does not direct the permit holders on how to determine baseline conditions for residualism or downstream migration, Chelan PUD developed the draft *Methodology for Establishing Baseline Conditions in the Wenatchee Steelhead Program* that the HCP Hatchery Committees reviewed in March 2018. Options to measure residualism included a PIT-tag evaluation, post-release sampling, and an electrofishing and angling study. The HCP Hatchery Committees discussed the options and methods for estimating rates of residualism, as well as sampling ideas and statistical approaches. The Hatchery Evaluation Technical Team met to discuss the draft plan in addition to the Hatchery Committees. Based on feedback from the HCP Hatchery Committees and the Hatchery Evaluation Technical Team, Chelan PUD indicated they intend to complete a PIT-tag evaluation and use gonadosomatic index (GSI) sampling to assess maturation. Only the lethal, post-release, GSI sampling required approval from the HCP Hatchery Committees, which was provided as follows: Chelan PUD, YN, CCT, WDFW, USFWS, and the NMFS approved on April 18, 2018. The PIT-tag study and GSI sampling occurred in 2019 as described in the draft *Methodology for Establishing Baseline Conditions in the Wenatchee Steelhead Programs* plan.

2.2.2.2.1.2 Wenatchee Steelhead Surplus and Precocial Maturation Study

In November 2018, WDFW and Chelan PUD notified the HCP Hatchery Committees that there was an overage in the Wenatchee steelhead program of about 21,000 excess hatchery-by-hatchery BY 2018 steelhead, which were destined for isolated ponds along Rock Island Reservoir. Chelan PUD developed a plan to study the effects of temperature regime on early maturation using 1,500 of the excess fish. Discussions with steelhead experts at National Oceanic and Atmospheric Administration (NOAA) yielded a recommendation to apply different temperature regimes to overwintering fish to evaluate whether transferring fish to the Chiwawa Acclimation Facility and rearing steelhead on colder water in November may be contributing to early maturation. Chelan PUD decided to rear 500 steelhead in each of three different locations (Eastbank Hatchery, Chiwawa Acclimation Facility, and Chelan Hatchery) with different temperature regimes at similar densities through early March, then transfer all 1,500 fish to the Chiwawa Acclimation Facility where final rearing occurs. The fish were lethally sampled in June 2019 to evaluate the effects of temperature regimes on precocial maturation using GSI sampling. The HCP Hatchery Committees discussed the overage and provided feedback on the study plan, particularly regarding what other data will be collected in addition to GSI sampling. Results will be provided in 2020.

2.2.2.3 Hatchery Monitoring and Evaluation Plan Implementation

2.2.2.3.1 *Hatchery Monitoring and Evaluation Plan – 2019 Update*

Chelan PUD hatchery M&E programs are operated in accordance with the *Monitoring and Evaluation Plan for PUD Programs*. The HCP Hatchery Committees revised the population genetics component of the plan (Objective 7) in 2019. Changes included comparing linkage disequilibrium of natural-origin and hatchery-origin fish over time; monitoring genetic status of hatchery-origin returns to evaluate potential genetic risks to the natural population; and employing equivalence testing in place of statistical hypothesis testing in the future when appropriate (described further in Section 2.2.2.3.5). A previous major revision was conducted in 2017 (to the *Monitoring and Evaluation Plan for PUD Programs – 2013 Update)*, as described in the 2017 Rocky Reach HCP Annual Report.

2.2.2.3.2 *Spatial Scales for Carcass Survey Analysis*

In October 2019, a question was raised about the appropriate spatial scale for analyzing hatchery and natural-origin female carcass distributions, as directed by the PUDs' M&E Plan: 2017 Update (and 2019 Update) and for consideration in the upcoming 10-year Comprehensive Review in 2020.

Management decisions could differ considerably depending on the scale of the analysis (e.g., 100 meters, 500 meters, 1 kilometer). Boundaries of the historical reaches that have been used for analyses over the long term are somewhat arbitrary, yet this is the largest dataset and should be preserved. Spatial distribution is very different depending on the species, size of the river, and reach characteristics such that one prescriptive scale for analysis is not biologically relevant for all cases. The HCP Hatchery Committees and PRCC Hatchery Sub-Committee agreed to evaluate female carcass distribution at the historical reach scale for comparison to past results and also to allow analysts to report distributions at a scale that is appropriate for each location and stock.

2.2.2.3.3 *Independent Scientific Advisory Board Recommendations*

In 2017 and 2018, the Independent Scientific Advisory Board reviewed habitat assessment, research and monitoring, and prioritization and coordination of recovery actions for spring Chinook salmon in the Wenatchee, Entiat, and Methow basins. Their final report, *Review of Spring Chinook Salmon in the Upper Columbia River*,[6] includes several recommendations pertaining to the Hatchery M&E Plan and its appendices. In February 2018, the HCP Hatchery Committees discussed the report and requested that Dr. Tracy Hillman (Chair of the HCP Hatchery Committees) begin updating the M&E Plan and its appendices and analyses as needed.

Hillman worked on this task throughout 2018 and 2019, reporting back to the committees regularly with updates. To date, his review has focused on the statistical analyses in Appendix H of the M&E Plan to compare the productivity of paired treatment streams with hatchery supplementation programs and control streams without hatchery supplementation programs. Improved statistical modeling of the treatment and control comparisons was performed and the methods were reviewed externally by Dr. Barb Downes (University of Melbourne) and Dr. Carl Schwartz (Simon Fraser University, retired). Updates to the plan and its appendices will continue in 2020 as the 10-year Comprehensive Review is developed.

2.2.2.3.4 *Hatchery Monitoring and Evaluation Implementation Plan*

The *Chelan County PUD Hatchery Monitoring and Evaluation Implementation Plan* is prepared annually to describe the M&E activities for the next calendar year. In August 2019, the HCP Hatchery Committees provided a draft annual M&E implementation plan for review. The genetic monitoring

---

6 Independent Scientific Advisory Board, 2018. Review of Spring Chinook Salmon in the Upper Columbia River. ISAB 2018-1. February 9, 2018. Available at: https://www.nwcouncil.org/sites/default/files/ISAB%202018-1UpColSpringChinookReview10AprilUPDATE.pdf.

objectives were updated to align with the changes made to the PUDs' M&E Plan: 2019 Update (as discussed in Section 2.2.2.3.1). The Rock Island and Rocky Reach HCP Hatchery Committees approved the Chelan PUD 2020 Hatchery M&E Implementation Plan (Appendix Q) on September 18, 2019, following a 30-day HCP Hatchery Committees review period.

2.2.2.3.5 *Genetic Analyses for Habitat Conservation Plan Program Species*

The M&E Plan specifies genetic analyses, which should occur at 10-year intervals in order to examine the potential for changes in genetic diversity of natural populations as a result of hatchery programs. In 2016, the HCP Hatchery Committees recognized the need to reconsider the genetic sampling intervals and scheduling for HCP program species.

WDFW worked on this task throughout 2016 and 2017. They conducted a review of what samples have been collected and analyzed and made a list of relevant reports that includes the results of past analyses. They developed a draft timeline for sample collection, analyses, and reporting to meet all monitoring objectives, and they investigated potential analyses with geneticists to inform updated sampling intervals. This material was shared with the HCP Hatchery Committees in January 2017, then revised and shared again in April 2017. The timeline includes analysis needs, the projected year of the analysis, and the requirements for M&E reporting. The HCP Hatchery Committees discussed whether analysis intervals should be based on listing status or other factors, and whether to synchronize analysis years for the same species across basins, or by each basin. A power analysis was proposed as a way to determine how large of a genetic change could be detected in a population and how rapid it may occur (which would inform the analysis interval). The HCP Hatchery Committees also recognized the need to identify a baseline genetic period for each program, because hatchery programs change over time, especially broodstock. It was determined that the WDFW genetics laboratory should perform a power analysis to inform recommended analysis frequency, and the HCP Hatchery Committees should identify baseline periods for each program. The WDFW Molecular Genetics Laboratory did not complete a power analysis citing the need to be funded to complete this task.

In February 2018, the HCP Hatchery Committees discussed how the timeline and intervals for genetic sampling depend largely on sample sizes and analysis intervals. It was determined that input from geneticists from multiple agencies would help determine a strategy for genetics M&E for the upper Columbia River (UCR) PUD hatchery programs. In June through August 2018, the HCP Hatchery Committees reviewed draft questions for geneticists regarding M&E and nominated geneticists to participate on a panel. The goal of asking questions of the panel was to ensure that genetic analyses and reporting completed as part of hatchery M&E answer appropriate genetic questions for each program. In September 2018, the HCP Hatchery Committees met with the panel of geneticists: Drs. Morgan Robinson (NOAA), Christian Smith (USFWS), Ilana Koch and Shawn Narum (Columbia River Inter-Tribal Fish Commission), and Todd Seamons (WDFW). Discussions focused on the

HCP Hatchery Committees' questions about genetics M&E for PUD programs and populations and processes of concern. Further coordination, questions, and data-sharing followed. In December 2018, the panel responded with consensus answers to the HCP Hatchery Committees' questions about genetics M&E in the memorandum, *Response to questions posed by the HCP Hatchery Committees regarding the PUD M&E Plan* (Appendix B). The HCP Hatchery Committees discussed the recommendations and conclusions of the panel in December 2018 and continued these discussions in 2019.

After reviewing the recommendations and conclusions of the panel, the HCP Hatchery Committees discussed revisions to Objective 7 (monitoring population genetics) of the M&E Plan. In January 2019, the HCP Hatchery Committees discussed the first recommendation, to consider linkage disequilibrium as a metric of genetic status and agreed to add analysis of linkage disequilibrium to the Hatchery M&E Plan. Throughout 2019, they revised the M&E Plan to update the genetic monitoring objectives of the plan and to incorporate linkage disequilibrium. The first set of edits to the plan incorporated an analysis of linkage disequilibrium (based on input from Todd Seamons [WDFW geneticist]) and the testing of statistical hypotheses for natural-origin baseline samples and natural-origin contemporary samples every 10 years. In August 2019, the HCP Hatchery Committees discussed the proposed changes and analysis frequency. Representatives emphasized the importance of putting genetic analysis results in context with the significance of the results by identifying a biologically meaningful effect size. They also revised the hypotheses in the plan to compare contemporary natural-origin fish to contemporary hatchery-origin fish and the natural-origin fish baseline. They discussed the need to analyze hatchery-origin fish and determined that hypotheses for sampling hatchery-origin fish should be program-specific. After further edits, in September 2019 the HCP Hatchery Committees agreed to add hypotheses to the genetic monitoring objectives for equivalence testing approaches in addition to the standard null-hypothesis testing approaches based on suggestions from the Independent Scientific Advisory Board and M&E Plan authors. They sought additional input from geneticists Christian Smith (USFWS) and Todd Seamons to determine biologically significant effect sizes but were not able to prescribe an effect size for the plan. Rather, revisions to the hypotheses reflect the understanding that multiple aspects of a program (such as genetics, stray rate, and productivity) affect how the hatchery population affects the natural population. After completion of the Comprehensive Review, more information will be available to refine the hypotheses.

The HCP Hatchery Committees finalized changes to Objective 7 of the Hatchery M&E Plan with approval of the *Monitoring and Evaluation Plan for PUD Hatchery Programs: 2019 Update* on December 24, 2019 (Appendix R). The genetic analyses and statistical and equivalence testing described in the revisions will be implemented in 2020 and future years.

2.2.2.3.6 *Sampling at the Off-Ladder Adult Fish Trap*

In 2018, WDFW proposed a cost-sharing arrangement between WDFW and the PUDs to continue the existing steelhead PIT-tagging program at Priest Rapids Dam for steelhead (BY 2020 and beyond) to adjust for funding reductions from the Bonneville Power Administration and challenges to maintaining the aging PIT-tag infrastructure in the UCR.

In 2019, Douglas, Chelan, and Grant PUDs continued to consider the cost-share proposal outside the purview of the Hatchery Committees, focused on tagging steelhead at the off-ladder adult fish trap (OLAFT) at Priest Rapids Dam and maintaining critical PIT-tag arrays in tributaries used for estimating viable salmonid population metrics.

In January 2019, WDFW informed the HCP Hatchery Committees and PRCC Hatchery Sub-Committee of their intent to shift the focus from steelhead to spring Chinook salmon for mark-recapture model development for the estimation of spawning escapement and PIT-tagging efforts at the OLAFT, potentially affecting BY 2020 fish and beyond. The intent of an escapement model based on PIT-tag detections would be to allow for estimating spawning and pre-spawn mortality rather than relying on spawner surveys to fill a knowledge gap for estimating the number of spring Chinook salmon that return to the Upper Columbia compared to the number that successfully spawn. It was noted that some double-handling of fish could occur across the basin, which could exacerbate pre-spawn mortality, but potentially fewer fish would be handled overall. Reliance on spring Chinook salmon redd and carcass surveys would continue for monitoring the distribution of natural-origin and hatchery-origin spawners, redd distribution, and escapement.

Noting that the PUDs' implementation plans were drafted in advance of WDFW's proposal to shift from PIT-tagging steelhead to spring Chinook salmon in 2019, language documenting the use of the PIT-tag based escapement estimates for steelhead were maintained in the Chelan PUD 2019 Hatchery M&E Implementation Plan that was approved in 2018, and the approved Chelan PUD 2020 Hatchery M&E Implementation Plan. Steelhead were PIT-tagged at the OLAFT in 2019 as in previous years

2.2.2.3.7 *Hatchery Monitoring and Evaluation Plan Reporting*

In September 2019, the Chelan PUD 2018 Hatchery M&E Plan Report, titled *Monitoring and Evaluation of the Chelan and Grant County PUDs Hatchery Programs 2018 Annual Report,* which documented M&E activities in 2018 (Appendix S), was finalized following a 30-day HCP Hatchery Committees review period.

In addition, Chelan PUD began working with the HCP Hatchery Committees in 2016 to develop a long-term scheduling plan to logically orchestrate HCP requirements and M&E reporting, including annual and 5-year statistical reports, and the 10-year Comprehensive Review (Rocky Reach HCP: Section 8.7). The *Final M&E Reporting Schedule for the PUD Hatchery Programs,* finalized in March 2017, describes the content and function of each report and development and due dates through 2052.

2.2.2.3.8 *Improving Homing in the Methow Basin: Adult Outplanting Plan*

In 2016, the HCP Hatchery Committees designed a pilot management plan to address Objective 5 (regarding homing and straying of hatchery fish) of the Hatchery M&E Plan. The HCP Hatchery Committees approved the Final Outplanting Adults Plan in April 2017 and intended to implement the study in 2017. However, the translocation study did not occur in 2017, 2018, or 2019 because the spring Chinook salmon runs were small and no surplus hatchery-origin adults were available for translocation. In 2019, the HCP Hatchery Committees re-considered the intent of translocating adult fish in years of low abundance. The original intent was to translocate fish as an alternative to acclimation of juveniles in upstream tributaries and to compare the success of outplanting adults with acclimation of juveniles. Given that runs may continue to be too small to implement the plan as written, alternative perspectives were discussed for prioritizing the productivity of natural spawning with outplanted fish over filling hatchery broodstock with natural-origin spawners, and to consider habitat capacity and improving productivity in reaches with low spawner densities by outplanting fish. Outplanting surplus eggs in artificially constructed redds in areas of low spawner densities was also suggested. Alternative outplanting scenarios that examine translocating different subsets of adults are currently being examined by WDFW and USFWS to determine their impact on proportionate natural influence (PNI) of both the hatchery and naturally spawning groups. The results of the analysis will be presented to the HCP Hatchery Committees and PRCC Hatchery Sub-Committee in 2020, with the goal of revising the adults outplanting plan for the Methow Basin as a stand-alone document that will be treated as experimental until methods can be proven feasible and repeatable in the future.

2.2.2.4 Okanogan Sockeye Salmon Mitigation

In 2018, Chelan PUD provided a thirteenth year of funding for a portion of the Okanagan Nation Alliance's (ONA's) Skaha Lake Sockeye Salmon Reintroduction Program (the current hatchery production obligation for Okanogan sockeye salmon mitigation is a combined 591,050 smolts for Rocky Reach and Rock Island HCPs). Chelan PUD funding contributed to the construction of the kł cp̓əlk̓ stim̓ Sockeye Salmon Hatchery in Penticton, British Columbia, which was completed in September 2014. Currently, Chelan PUD funding contributes to operation and maintenance of the hatchery and to the M&E program. In June 2015, the hatchery held its first official fish release of roughly 1.7 million fry, mostly in Shingle Creek, and some in Okanagan Lake as part of a ceremonial ONA release. The hatchery was designed to support up to an 8-million-egg program; however, the plumbing system initially installed supported a production capacity of 5 million eggs. The egg-take goal of 5 million eggs was achieved for the first time in 2016. In spring 2018, the hatchery released roughly 1,220,000 fry (Chelan PUD's proportion was 414,800) into Skaha Lake.

2.2.2.4.1 *Annual Skaha and Okanogan Lake Sockeye Reintroduction Updates*

In November 2019, Ryan Benson of the ONA (British Columbia, Canada) gave a presentation entitled "*Skaha Lake Sockeye Re-introduction Program Update*" to the HCP Hatchery Committees and PRCC Hatchery Sub-Committee. A summary of hatchery operations and release strategies was given. The hatchery program produces sockeye salmon for reintroduction, with a capacity for producing up to 5 million eggs. In 2019, all fry were released into Lake Okanagan for the first time at three different sites in the lake. Survival and travel time through the Columbia River system are monitored by PIT-tag detections at downstream hydro-projects and survival in the lake is monitored by purse seining, though it can be difficult to recapture fish in the lake. No fry were stocked into Skaha Lake in 2019 due to naturally high escapement in 2018 from fish moving upstream through the Skaha Dam fishway. Reduced growth suggested that an optimum stocking density may have been exceeded in Skaha Lake in 2018, which may vary year to year depending on discharge rate through the lake and fish community dynamics between sockeye salmon, kokanee, and whitefish.

A new mandate allows reintroduction of sockeye salmon into the entire Okanagan Basin including Okanogan Lake, organized by the Okanagan Basin Salmon Restoration Sub-Committee, with support for ultimately releasing 4.2 million fry into Okanagan Lake, and eventually to other upstream lakes. One concern is sockeye salmon residualization and hybridization between sockeye salmon and kokanee.

Restoration actions being undertaken under the Okanagan River Restoration Initiative include gravel augmentation to the Penticton Channel and activation and improvements to the Penticton Dam fishway to pass adult fish into Lake Okanagan. The fishway was pilot tested in 2019 in preparation for early returns from the first large release of approximately 4.5 million sockeye salmon fry.

Implementation of the program has expanded in recent years with support of the Provincial British Columbia government, driven by federal participation in the United Nations Declaration on the Rights of Indigenous People. Implementation of the program activities has benefitted from the Canadian Okanagan Basin Technical Working Group, a successful model for cooperation that has been in place since the 1990s.

2.2.2.5 Hatchery and Genetic Management Plans

Efforts continue to complete the consultation process, including coordination in prior years among Chelan PUD, NMFS, USFWS, the YN, WDFW, the CCT, and Grant and Douglas PUDs.

2.2.2.5.1 *Wenatchee Steelhead*

On October 30, 2015, NMFS issued a Biological Opinion (BiOp) on the Wenatchee River Summer Steelhead Hatchery Program. On November 27, 2017. USFWS, in coordination with NMFS, issued a BiOp for the impact of Wenatchee River programs on bull trout, including the Chiwawa Spring Chinook Salmon, Wenatchee Steelhead, and Wenatchee Summer Chinook Salmon Programs on

November 27, 2017. NMFS issued Section 10 (a)(1)(A) Permit No. 18583 to WDFW, Chelan PUD, and the Yakama Nation (as an authorized agent of Chelan PUD) on December 26, 2017. The permit expires on December 31, 2027.

2.2.2.5.2 *Methow Spring Chinook Salmon*

Rocky Reach HCP Hatchery Committee approved the Chelan PUD Methow Spring Chinook Salmon Hatchery and Genetic Management Plan (HGMP) in March 2014.

NMFS issued the final permits for the combined Methow spring Chinook salmon programs, including Permit 20533 for Chelan PUD, in February 2017, and they will expire in December 2027.

2.2.2.5.3 *Chelan Falls Summer Chinook Salmon*

In May 2013, NMFS requested that Chelan PUD and other Permit No. 1347 permit holders submit letter applications for extension of Permit No. 1347. NMFS indicated that an extension of the existing Permit No. 1347 was feasible. Chelan PUD submitted an extension request letter on August 27, 2013. Subsequently, on September 20, 2013, Chelan PUD received a letter from NMFS indicating that the existing ESA permits would be extended until new consultations are completed, and new permits issued. In 2014, NMFS indicated that, due to higher priority permitting of programs rearing ESA-listed species, permitting of summer and fall Chinook salmon programs would not be addressed until spring 2015. In 2015, permitting of summer and fall Chinook salmon programs was postponed again because parties agreed that these programs are the lowest priority for completing consultation.

In May 2017, NMFS indicated they were drafting the proposed action for the batch of unlisted Chinook salmon programs in the UCR (Wenatchee summer Chinook, Chelan Falls summer Chinook, Wells summer Chinook, Priest Rapids fall Chinook, Methow summer Chinook, and Ringold upriver bright fall Chinook), and would be coordinating with parties to gain needed information. In June 2017, the HCP Hatchery Committees discussed possible consultation pathways for the unlisted programs. In September 2017, NMFS indicated that the BiOp for the Columbia River unlisted summer Chinook salmon programs is being drafted. The applicants officially initiated consultation with request letters in November 2017, and NMFS responded with letters of sufficiency to the applicants on November 25, 2017. The draft BiOp was available for the applicants and HCP Hatchery Committees to review and was finalized on December 26, 2017.

On November 20, 2017, NMFS requested informal consultation with USFWS under Section 7(a)(2) of the ESA on the proposed permitting of the Chelan Falls Summer Chinook program. Informal consultation was completed by USFWS on December 21, 2017.

In February 2018, NMFS indicated that the Section 10 ESA permit for the Chelan Falls summer Chinook salmon program would be issued after completion of the National Environmental Policy Act process, including an environmental assessment (EA) encompassing the Methow steelhead and unlisted programs (summer/fall Chinook salmon for Wells, Methow, Chelan Falls, Dryden, and Priest Rapids hatcheries). In September 2018, NMFS indicated the draft EA was under internal review, and an addendum for the HGMP should also be submitted to NMFS with updated information about the proposed action from the most recent BiOp. Chelan PUD reviewed the draft EA in October 2018. In November 2018, NMFS indicated that HGMP addenda were complete for the programs covered by the EA for the UCR steelhead and summer/fall Chinook salmon programs. The EA and HGMPs were reviewed internally by NMFS in March 2019 and made available for a 30-day public comment period in April 2019. No substantive comments were submitted from the public. NMFS finalized the Finding of No Significant Impact in July 2019 stating the actions will not have a significant impact to the environment; therefore, an environmental impact statement will not be necessary. The final EA and Section 10 ESA permits for the Chelan PUD summer Chinook salmon programs were finalized and signed in September 2019 and will expire in 2030.

2.2.2.6 Wenatchee Steelhead Relative Reproductive Success Study

The Rocky Reach HCP, Section 8.5.3, requires that Chelan PUD fund and implement a steelhead relative reproductive success (RRS) study. The Wenatchee Steelhead RRS Study began in 2008 and incorporated data from each subsequent BY to 2011. The study objective was to measure the RRS of hatchery-origin steelhead in the natural environment and determine the degree to which any differences in reproductive success between hatchery- and natural-origin steelhead can be explained by measurable biological characteristics.

In September 2015, WDFW and NMFS presented to the HCP Hatchery Committees the results of the Wenatchee Steelhead RRS Study. In summary, many differences in life-history traits were detected between hatchery and natural fish; however, there were no apparent differences in spawn timing. Additionally, spawning distribution was similar. Hatchery-by-hatchery broodstock male and female fish had the lowest RRS. Hatchery-by-wild broodstock male and female fish had an RRS between those of hatchery-by-hatchery broodstock and wild-by-wild broodstock. Wild-by-wild male and female fish had almost indistinguishable RRS from wild fish, though the RRS had greater variance between years. Size and season also contributed to variation in RRS among individuals. An SOA documenting the completion of the steelhead RRS study will be brought to the HCP Hatchery Committee in 2020.

2.2.2.7 Multi-Species/Expanded Acclimation

In the interest of developing a long-term, multi-species/acclimation plan for UCR salmon mitigation programs, in January 2013, the Joint Fisheries Parties developed a plan outlining multi-species acclimation options for UCR salmon and steelhead mitigation programs. Throughout 2013 and 2014, the YN further discussed with the HCP Hatchery Committees potentially expanding acclimation areas in the Upper Methow Basin and agreed to develop a document summarizing the details of these plans.

2.2.2.7.1 *Methow Spring Chinook Salmon at Goat Wall Acclimation Site*

In October 2014, after review by the HCP Hatchery Committees of the YN's initial proposal to acclimate 50,000 spring Chinook salmon at one of two acclimation sites in the Upper Methow Basin, the YN proposed acclimating 25,000 Methow spring Chinook salmon at the Goat Wall Acclimation Site, located on the Methow River approximately 20 miles upstream of the site used in the past (the Mid-Valley Pond site), and 25 miles upstream of the town of Winthrop. The site is located on a side channel to the Methow River named Cold Creek that conveys approximately 100 cfs in the spring, with water levels that are connected to water levels within the mainstem river. The acclimation area is 30 feet by 100 feet (0.08 acre) with an average depth of 3 feet, flows of 3 to 15 cfs, and water temperatures that ranges from high 30s°F to mid 40s°F, resulting in a capacity of 30,000 smolts at a size of 16 fish per pound and a conservative stocking density. The HCP Hatchery Committees requested that the YN prepare a proposal for expanded acclimation in the Methow Basin, including an explanation of pond operations, tagging, M&E, project objectives, and adult management, to be further discussed in 2015.

In January 2015, the YN, in coordination with the HCP Hatchery Committees, developed a Draft YN Upper Methow Spring Chinook Salmon Acclimation Proposal, as requested. The proposal was to acclimate 25,000 Methow spring Chinook salmon at the Goat Wall Acclimation Site as part of the YN's Upper Columbia Spring Chinook Salmon and Steelhead Acclimation Project (Bonneville Power Administration Project No. 2009-00-001), beginning with the 2016 release (BY 2014), and with releases continuing through 2020. The YN also distributed a Draft Goat Wall Acclimation SOA for HCP Hatchery Committees review. In February 2015, the HCP Hatchery Committees further discussed the draft proposal and SOA (which were also vetted with the Joint Fisheries Parties), and the Wells and Rocky Reach HCP Hatchery Committees approved the YN *Upper Methow Spring Chinook Acclimation Proposal* and Goat Wall Acclimation SOA, with NMFS abstaining, as follows: the YN approved on March 3, 2015; NMFS abstained on March 3, 2015; Chelan PUD, Douglas PUD, WDFW, and the CCT approved on March 4, 2015; and USFWS approved on March 5, 2015.

Chelan PUD and Douglas PUD requested that the YN have its own ESA permit coverage for the planned releases. NMFS indicated, however, that it was unlikely to have permits in place before March 2016 when the fish would need to be transferred. The YN, NMFS, and HCP Hatchery Committees explored options for how to move fish to the site and determined it cannot be done without the proper permits in place. Therefore, due to permitting delays, a 2016 release did not happen, despite HCP Hatchery Committees approval of the proposal and SOA.

NMFS issued a permit to YN for these activities in February 2017.

The YN has now released spring Chinook salmon from the Goat Wall Acclimation Site over 3 years and provided a summary of the past 3 years of activities in 2019 (Table 6).

Table 6
Juvenile Spring Chinook Salmon Released from the Goat Wall Acclimation Site

Release Year	Number Received	Number Released	Transfer Date	Release Start Date	Release End Date	Number PIT-Tagged
2017	25,978	25,894	3/30	4/17	4/26	4,934
2018	28,535	27,970	3/15	4/18	4/29	4,425
2019	29,810	29,777	4/2	4/22	4/30	4,971

The acclimation pond is fully enclosed by nets. Fish transfer date depends on flows and site accessibility and release date is timed to coincide with Methow Fish Hatchery release dates in order to compare survival between the two. A subset of the acclimated fish is PIT-tagged to observe pre-release and post-release survival and travel times. PIT-tag detection systems at the downstream end of the site are used to monitor for fish escapes prior to the release date, estimate survival during the acclimation period, and monitor emigration time once the nets are opened. Escape rates were low (approximately 1.2%) and modeled survival rates during acclimation were relatively high (greater than 98%). Acclimated fish had similar outmigration survival and travel times as fish released from Methow Fish Hatchery to McNary Dam (on the mainstem Columbia River). 2019 is the first year in which adult returns from the study were observed with estimated smolt-to-adult return rates that were similar to those from other Methow Basin hatcheries and acclimation sites. Monitoring of the distribution of adult spawners began in 2019 in order to observe whether study fish showed evidence of homing to the acclimation site; however, it is expected that there may be limitations to interpreting data from spawner surveys in one year because the total run-size was expected to be low in 2019.

The YN intends to conduct a total of 5 years of spring Chinook salmon releases from the Goat Wall Acclimation Site. The Committee discussed an appropriate timeline to evaluate site performance because the complete adult return data may not be available until several years following the last release. Representatives agreed that preliminary evaluations will be valuable, and that evaluation of juvenile performance could be carried out prior to collection of all adult survival and distribution data.

2.2.2.7.2 *Methow Spring Chinook and Coho Salmon at Chewuch Pond*

In 2019, Methow spring Chinook salmon and coho salmon were co-acclimated at Chewuch Pond, a second site in the Methow Basin. The acclimation pond was operated by Chelan PUD. This year was the first year of acclimating coho simultaneously with spring Chinook salmon, with 80,000 coho salmon acclimated in the pond.

2.2.2.8 Egg-to-Emergence Evaluation in the Chelan River

As in 2017, in 2018 Chelan PUD requested surplus steelhead eggs from Douglas PUD to conduct an egg-to-emergence evaluation in the habitat channel of the Chelan River to evaluate the effectiveness of Chelan PUD's Chelan River Biological Evaluation and Implementation Plan. In 2017, researchers used green eggs from Wells Fish Hatchery. In 2018, the study involved using 2,800 eyed eggs from four pairs of broodstock. The Rocky Reach and Rock Island HCP Hatchery Committees approved Chelan PUD's request to collect four female and four male surplus steelhead broodstock from the Wells Fish Hatchery Volunteer Channel to support the egg-to-emergence evaluation in 2018. Chelan PUD spawned the surplus broodstock in March 2018 and planted the eyed eggs in mid-April 2018. Results will be available from the Chelan River Fishery Forum in 2020.

2.2.2.9 Adult Prophylactic Disease Management Plan for Eastbank Fish Hatchery Complex Spring and Summer Chinook Programs (2018-2020)

In 2018, WDFW distributed an Adult Prophylactic Management Plan for Eastbank Fish Hatchery Complex Spring and Summer Chinook Salmon Programs in 2018-2020 to the HCP Hatchery Committees. WDFW reviewed the plan, which includes a trend away from using antibiotics in prophylactic treatments. The HCP Hatchery Committees discussed which aspects of fish health are the purview of the committees and the importance of communication between fish health staff at different hatcheries and agencies. The initial plan was approved by the HCP Hatchery Committees and implemented in 2018. It was also proposed that the plan be incorporated as an appendix to the Broodstock Collection Protocols in future years.

In 2019, Chelan PUD and WDFW staff revised the plan and included it as Appendix J of the 2019 Broodstock Collection Protocols (Appendix O to this report), *2018-2020 Brood year Adult Prophylactic Disease Management Plan for Eastbank Fish Hatchery Complex Spring and Summer Chinook Hatchery Programs*. The HCP Hatchery Committees approved the plan during approval of the Broodstock Collection Protocols. The goals of the plan are to ensure integrated and/or recovery programs make the most efficient use of natural-origin broodstock and maximizing natural-origin spawners while minimizing handling and unnecessary activities. The plan describes the proposed methods, including the timing and approach for prophylactic treatment, PIT-tagging strategies, and the program-specific plans for BY 2019.

In 2020, WDFW and Chelan PUD will evaluate results to determine if modifications are needed for BY 2020.

2.2.2.10 Meeting Logistics

The HCP Hatchery Committees and PRCC Hatchery Sub-Committee continued holding joint sections of meetings in 2019 when agenda items pertain to both sets of committees. To further streamline processes for both committee groups, meeting facilitation and support were merged. A single set of merged HCP Hatchery Committees and PRCC Hatchery Subcommittee meeting protocols and distribution lists was agreed to in May 2019 (Appendix B). Merged protocols outlined the approaches for decision making, resolving disputes and conflicts, meeting logistics, records maintenance and distribution, and review of plans and reports. Previously, the HCP Hatchery Committees had drafted a Conflict of Interest SOA that would require members with a personal interest in a decision item to recuse themselves from voting. However, it was determined that because the HCP Hatchery Committees and PRCC Hatchery Subcommittee operate on consensus, the personal interest of a single member could not individually affect a decision. Therefore, the HCP Hatchery Committees agreed not to renew the Conflict of Interest SOA as part of streamlining the meeting protocols.

The Committees discussed the current recipient list for HCP Hatchery Committees and PRCC Hatchery Sub-Committee materials via email, and the utility and objective for using email as a primary means for document distribution. A primary distribution list was developed for the distribution of all materials, draft and final, that included the Committees' and Subcommittee's representatives and alternates, as well as a small group of interested parties whose participation is necessary for reviewing documents. A secondary distribution list was developed that included a broader list of recipients to be copied only on the final versions of agendas, minutes, plans, reports, and other documents. The revised and merged distribution lists were approved by the HCP Coordinating Committees in May 2019. All materials pertaining to the given Committees and Subcommittee will continue to be posted to their respective internal Extranet and SharePoint sites, as well as external websites, per requirements of the HCPs and Priest Rapids Settlement Agreement to maintain documents for the public record.

A summary of HCP Policy Committees guidance directed toward the HCP Hatchery Committees was included in the meeting protocols regarding the process and criteria for elevating topics from the HCP Hatchery Committees to the Policy Committees. The specific guidance resulted from an issue raised in the HCP Tributary Committees that could not be resolved because policy-level considerations took precedence over biological relevance (described in Section 2.3). The following guidance was added to the meeting protocols in October 2019 (Appendix B):

> HCP Hatchery Committees will base decisions on technical merit, and notify respective HCP Coordinating and Policy Committees representatives of any potential policy issues needing to be addressed in those forums.

2.2.3 Maintenance and Improvements

2.2.3.1 Chelan Fish Hatchery Rehabilitation Design

In 2015, a rehabilitation feasibility study began for the Chelan Fish Hatchery Building, which is more than 60 years old. Rehabilitation is planned for the existing hatchery building, including the offices, incubation, early rearing, and ancillary functions. No program changes are proposed at this time. The feasibility study continued in 2016 and will be finalized in 2020.

2.2.3.2 Chelan Falls Canal Trap Engineering Feasibility

In January 2018, Chelan PUD indicated to the HCP Hatchery Committees that a more permanent structure for the Chelan Falls canal trap is being considered. The feasibility of designing permanent facilities for summer Chinook salmon broodstock collection at Chelan Falls was completed in 2019 and Chelan PUD decided not to move forward with design work due to the high cost of constructing a permanent broodstock collection facility at the site.

2.2.3.3 Eastbank Fish Hatchery Generator

In September 2018, Chelan PUD installed a generator as a second backup power source at the Eastbank Fish Hatchery. Programming to automate generator power was finalized in 2019.

2.3 Habitat Conservation Plan Tributary Committees and Plan Species Accounts

As outlined in the Rocky Reach HCP, the signatory parties each designated one member to serve on the HCP Tributary Committee. The Rock Island, Rocky Reach, and Wells HCP Tributary Committees meet on a regularly scheduled basis as a collective group to enhance coordination and minimize meeting dates and schedules. Subject items requiring decisions are voted on in accordance with the terms outlined in the specific HCPs. During 2019, the Rocky Reach HCP Tributary Committee met on nine occasions.

An initial task of the HCP Tributary Committees in 2019 was to review and update their operating procedures that provide a mechanism for decision making. These were initially developed in 2005 and were included in that year's annual report (Anchor 2005).[7] The HCP Tributary Committees also developed Policies and Procedures for soliciting, reviewing, and approving project proposals (Anchor 2005). The Policies and Procedures provide formal guidance to project sponsors on submission of proposals for projects to protect and restore habitat of Plan Species within the geographic scope of the HCP. The HCP Tributary Committees established two complementary funding programs, the General Salmon Habitat Program (GSHP) and the Small Projects Program.

In 2019, the HCP Tributary Committees reviewed their Policy and Procedures document and made edits to clarify language in Section 2.0 (Funding Programs). In addition, the HCP Tributary Committees developed specific evaluation criteria for Section 5.0 (Review Procedures; see Appendix T). Different criteria were established for evaluating restoration, protection, design, and

[7] Anchor Environmental, L.L.C. 2005. Annual Report, Calendar Year 2005, of Activities under the Anadromous Fish Agreement and Habitat Conservation Plan. Rocky Reach Hydroelectric Project, FERC License No. 2145. Prepared for FERC by Anchor Environmental L.L.C. and Public Utility District No. 1 of Chelan County.

assessment projects. Criteria include an evaluation of biological and technical merit, feasibility, durability, and cost effectiveness. Finally, the HCP Policy Committees provided the HCP Tributary Committees guidance on how the HCP Tributary Committees evaluate proposals and make funding decisions (see Section 2.3.3). Those guidelines were incorporated into the Policies and Procedures document.

The HCP Tributary Committees also reviewed and updated their Operating Procedures. The YN designated Brandon Rogers as their voting member and Hans Smith as the alternate on the Wells HCP Tributary Committee.

The HCP Tributary Committees continued the process of identifying high-priority, targeted, habitat projects within each of the Wenatchee, Entiat, Methow, and Okanogan subbasins. Based on the HCP Tributary Committees' extensive knowledge of the subbasins, limiting habitat factors, threats, and limiting life stages, they will identify enhancement or protection actions within each subbasin and call for proposals to implement those actions. They will work closely with the Upper Columbia Regional Technical Team on identifying high priority habitat actions. This is similar to the Bonneville Power Administration Targeted Solicitation Process. Although the HCP Tributary Committees will continue to accept project applications from sponsors anytime during the year, they plan to take a more active role in identifying and funding targeted projects within each subbasin. The HCP Tributary Committees are currently working with project sponsors on developing large, floodplain restoration projects in the Methow and Entiat rivers, and in Peshastin Creek, a tributary to the Wenatchee River.

Dr. Tracy Hillman continued as the Chairperson for the Rocky Reach HCP Tributary Committee. In 2019, the HCP Tributary Committees conducted a formal evaluation of the Chairperson and agreed unanimously to retain Dr. Hillman as the Chairperson for the next three-year period (2020 through 2022). Dr. Hillman is an Ecological Society of America board-certified senior ecologist and chief executive officer of BioAnalysts, Inc. He has over 30 years of experience as an ecologist and has chaired the Rocky Reach HCP Tributary Committee since 2007.

2.3.1 Regional Coordination

Similar to the HCP Hatchery Committees and to improve coordination, a representative from Grant PUD and the facilitator of the PRCC Habitat Sub-Committee were invited to the HCP Tributary Committees monthly meetings. In addition, these representatives received meeting announcements, draft agendas, and meeting minutes. This benefits the HCP Tributary Committees through increased coordination and the sharing of expertise. The Grant PUD representative and PRCC Habitat Sub-Committee facilitator have no voting authority within the HCP Tributary Committees.

The HCP Tributary Committees also coordinate with the Upper Columbia Salmon Recovery Board (UCSRB). Coordination is typically between the chairperson of the HCP Tributary Committees and the

Executive Director or the Natural Resource Program Manager of the UCSRB. In addition, some members of the HCP Tributary Committees typically attend UCSRB meetings to foster coordination in developing and selecting projects for funding. Some members of the HCP Tributary Committees are also members of the UCSRB's Regional Technical Team, which increases coordination in selecting projects for funding. Many of the Policies and Procedures of the Salmon Recovery Funding Board (SRFB) and HCP Tributary Committees are complementary, and annual funding rounds by these funding entities have been coordinated since 2005.

In addition to coordinating with the SRFB process and the PRCC Habitat Sub-Committee, the Rocky Reach HCP Tributary Committee coordinates funding of GSHP proposals with Bonneville Power Administration and the U.S. Bureau of Reclamation. The purpose of this coordination, according to Section 2 of the Tributary Fund Policies and Procedures for Funding Projects, is to collaborate with regional, local, state, tribal, and national organizations that fund salmon habitat projects. The efforts resulted in identification of possible cost-shares for suitable habitat restoration projects.

2.3.2 Fiscal Management of Plan Species Accounts

The HCP Tributary Committees set up methods for the long-term management of the Plan Species accounts for each HCP. The Rocky Reach HCP Tributary Committee appointed the accounting firm Clifton Larson Allen to perform the necessary tasks for fiscal management of the Rocky Reach Plan Species Account. These tasks include the following: 1) develop a long-term approach to maintain the funds and to carry out tax calculations and reporting; 2) conduct the daily management of activities (such as processing of invoices); and 3) provide technical expertise on financial matters to the committees. The beginning balance of the Rocky Reach Plan Species Account on January 1, 2019 was $2,888,124.61. Chelan PUD's annual contribution was $371,474.00. Interest received during 2019 was $39,645.00. Funds disbursed for projects in 2019 totaled $30,813.04. In addition, $4,290.97 was paid to Clifton Larson Allen and Chelan PUD for account administration, $1,000.00 was paid to the UCSRB for sponsorship in the 2020 Upper Columbia Science Conference, and $67.00 was paid in bank fees. The ending balance on December 31, 2019, was $3,263,072.60. The 2019 Annual Financial Report for this Plan Species Account is provided in Appendix U.

The Rocky Reach HCP Tributary Committee delegated signatory authority to the Chairperson for processing of payments for invoices approved by the HCP Tributary Committee, with the HCP Coordinating Committee Chairperson serving as the alternate. Chelan PUD recognizes the uniqueness of the Rocky Reach HCP Tributary Committee decision-making process and delegation of signatory authority to the Chairperson, and the Chelan PUD subsequently has provided funding necessary to assign reasonable liability insurance to the Tributary Chairperson.

2.3.3 Criteria for Making Funding Decisions

In late 2018 the HCP Tributary Committees evaluated a GSHP proposal that was supported by all parties on a technical level but was not supported by one party on a policy level. Thus, because of policy-level intervention, the HCP Tributary Committees elected not to fund the project. As a result, in February 2019, the YN offered a draft SOA titled, *Basis for Decision Making in HCP Tributary Committees,* which addressed the process and criteria by which the HCP Tributary Committees make funding decisions (Appendix V). The purpose of the SOA was to make sure all funding decisions made by the HCP Tributary Committees are based only on the merits of the project (biological benefit, technical merit, durability, feasibility, and cost effectiveness). Any criteria having no direct nexus to Plan Species, their habitat, or their management cannot be considered when evaluating proposed projects. The SOA also noted that any signatory attempting to vote on the basis of criteria other than those directly related to resource impacts may abstain from voting. The SOA was not supported by the HCP Tributary Committees. In June 2019, the YN formally initiated the dispute resolution process; however, because of timing issues and the need for the dispute to be addressed first by the HCP Coordinating Committees as outlined in the HCPs, the YN withdrew the formal dispute and requested the HCP Policy Committees convene to discuss the issue. The HCP Policy Committees met on July 9, 2019, and provided the following guidance specific to the HCP Tributary Committees (see Section 3.2):

- HCP Tributary Committees will base funding decisions on technical merit, biological benefit, durability, feasibility, and cost effectiveness (using the specific evaluation criteria in Section 5 of the Policies and Procedures document) and will notify respective HCP Coordinating and Policy Committees' representatives of any potential policy issues needing to be addressed in those forums.
- The HCP Tributary Committees should consider abstention in lieu of disapproval to preserve respective policy positions.

2.3.4 General Salmon Habitat Program

The HCP Tributary Committees established the GSHP as the principal mechanism for funding projects. The goal of the program is to fund projects for the protection and restoration of Plan Species habitat. An important aspect of this program is to assist project sponsors in developing practical and effective applications for relatively large projects. Many habitat projects are increasingly complex in nature and infeasible without extensive design, permitting, and public participation. Often, a reach-level project involves many authorities and addresses more than one habitat factor. Because of this trend, the GSHP was designed to fund relatively long-term projects. There is no maximum financial request in the GSHP; the minimum request is $100,000, although the HCP Tributary Committees may approve lesser amounts during a phased project.

The HCP Tributary Committees accept GSHP applications at any time during the year. They also accept SRFB applications for projects where Plan Species Account Funds are included as cost-shares in SRFB proposals.

In an effort to coordinate with ongoing funding and implementation programs within the region, the HCP Tributary Committees used the previously established technical framework and review process for this geographic area and worked with the other funding programs to identify cost-sharing procedures (see Section 2.3.1).

2.3.4.1 2019 General Salmon Habitat Projects

The SRFB announced its 2019 funding cycle in March, with draft proposals due on April 12, 2019, and final proposals due on June 28, 2019. The HCP Tributary Committees received and reviewed 18 draft SRFB proposals. The HCP Tributary Committees identified eight projects they believed warranted full proposals and dismissed ten projects because they were inconsistent with the intent of the Tributary Fund, did not have strong technical merit, were not cost effective, or were funded by another funding entity.

In July, the HCP Tributary Committees received 12 full SRFB proposals to the GSHP. All were cost-shares with the SRFB or other funding entities. The HCP Tributary Committees approved funding for six projects. In addition, the HCP Tributary Committees received five full proposals to the GSHP that were outside the SRFB process. Table 7 identifies the projects, sponsors, total cost of each project, amount requested from Tributary Funds, and, if funded, which Plan Species Account supported the project.

Table 7
General Salmon Habitat Program Projects Reviewed by the Habitat Conservation Plan Tributary Committees in 2019

Project Name	Sponsor[1]	Total Cost	Request from Tributary Committee	Plan Species Account[2]
Salmon Recovery Funding Board Applications				
Nason and Kahler Creek Confluence Acquisition	CDLT	$369,150	$184,575	Not funded [3]
Restore Lower Chiwaukum Creek – Phase 1	CCFEG	$116,256	$55,098	RI: $55,098
Monitor Side Channel Construction	CCNRD	$296,530	$148,265	RI: $148,265
Peshastin River Mile 4.3 Side Channel	CCNRD	$99,010	$19,802	RI: $19,802
IPID Full Season Pumping Project	CCNRD	$135,000	$67,500	Not funded
Nason Ridge Acquisition	CCNRD	$5,500,000	$500,000	RI: $500,000
Wenatchee EDT Model Development	CCNRD	$318,000	$48,000	Not funded
Lower Wenatchee Instream Flow Enhancement	TU	$2,500,000	$250,000	RI: $250,000
Upper Burns & Angle Point Areas Enhancement	YN	$1,070,500	$189,000	RI: $189,000

Project Name	Sponsor[1]	Total Cost	Request from Tributary Committee	Plan Species Account[2]
Golden Doe Large Wood Project	YN	$1,004,590	$200,270	Not funded
Upper Methow Restoration Assessment and Design	CCFEG	$80,200	$35,500	Not funded
Okanogan Basin Barrier Assessment	CCFEG	$193,826	$22,000	Not funded
General Salmon Habitat Program Applications				
Upper Kahler Stream and Floodplain Enhancement	YN	$482,500	$149,000	RI: $149,000
Stormy Project Area "A" Stream and Floodplain	YN	$1,564,211	$823,161	RR: $823,161
Johnson Creek US Hwy 97 Habitat Restoration	TU	$1,562,455	$267,547	W: $267,547
Evaluating Environmental Impacts of Tumwater Dam	CCFEG	$279,600	$139,800	Not funded
2019 Eightmile Creek Fisheries Assessment	WDFW	$130,183	$125,183	Not funded

Notes:

1. CCFEG = Cascade Columbia Fisheries Enhancement Group; CCNRD = Chelan County Natural Resources Department, CDLT = Chelan-Douglas Land Trust, TU = Trout Unlimited, WDFW = Washington Department of Fish and Wildlife, and YN = Yakama Nation.
2. RI = Rock Island Plan Species Account; RR = Rocky Reach Plan Species Account; W = Wells Plan Species Account.
3. The Nason and Kahler Creek Confluence Acquisition Project was funded by the PRCC Habitat Sub-Committee.

In 2019, the Rocky Reach HCP Tributary Committee agreed to fund the following GSHP project:

- **Stormy Project Area "A: Stream and Floodplain Project** for the amount of $823,161 (with cost share the total cost of the project was $1,564,211). This project will construct ten mainstem log structures and two perennial side channels within the middle Entiat River. One side channel will be 200-feet long; the other will be 2,500-feet long. Large wood will also be placed throughout the side channels. This work will maintain salmon and steelhead spawning habitat within the middle Entiat River, improve mainstem juvenile rearing and adult holding habitat, and improve off-channel juvenile rearing habitat.

2.3.4.2 Modifications to General Salmon Habitat Program Contracts

In 2019, the Rocky Reach HCP Tributary Committee received no requests from sponsors asking for modifications to GSHP projects funded by the Committee.

2.3.5 Small Projects Program

The Small Projects Program has an application and review process that increases the likelihood of participation by private stakeholders that typically do not have the resources or expertise to go through an extensive application process. The HCP Tributary Committees encourage small-scale projects by community groups, in cooperation with landowners, to support Plan Species recovery on private property. Project sponsors may apply for funding at any time, and in most cases, will receive a funding decision within three months. The maximum contract allowed under the Small Projects Program is $100,000.

2.3.5.1 2019 Small Projects

In 2019, the HCP Tributary Committees received three requests for funding under the Small Projects Program. Table 8 identifies the projects, sponsors, total cost for each project, amount requested from Tributary Funds, and which Plan Species Account supported the projects.

Table 8
Projects Reviewed by the Habitat Conservation Plan Tributary Committees under the Small Projects Program in 2019

Project Name	Sponsor[1]	Total Cost	Request from Tributary Committee	Plan Species Account[2]
East Fork Mission Creek Floodplain Restoration	CCNRD	$96,169	$74,669	Not funded
Napeequa Side Channel Connection	CCFEG	$58,290	$49,399	RR: $49,399
Sugar Levee Ground Water Evaluation	MSRF	$5,404	$2,940	W: $2,940

Notes:

1. CCFEG = Cascade Columbia Fisheries Enhancement Group; CCNRD = Chelan County Natural Resources Department, and MSRF = Methow Salmon Recovery Foundation.
2. RI = Rock Island Plan Species Account; RR = Rocky Reach Plan Species Account; W = Wells Plan Species Account.

In 2019, the Rocky Reach HCP Tributary Committee agreed to fund the following Small Project:

- **Napeequa Side Channel Connection Project** for the amount of $49,399 (with cost share the total cost of the project was $58,290). This project will remove a culvert and associated fill to restore hydraulic connectivity to a side channel along the lower Napeequa River, a tributary to the White River. This action will improve juvenile steelhead and spring Chinook salmon survival and productivity by providing access to an important spring-fed side channel.

2.3.5.2 Modifications to Small Project Contracts

In 2019, the Rocky Reach HCP Tributary Committee received no requests from sponsors asking for modifications to Small Projects funded by the Committee.

2.3.6 Tributary Assessment Program

The Rocky Reach HCP established the Tributary Assessment Program (separate from the Rocky Reach Plan Species Account) to fund M&E of the relative performance of projects funded by the initial contribution to the Plan Species Account. The Tributary Assessment program comprised a fixed (one time) contribution of $200,000, not subject to inflation adjustment. The Rocky Reach HCP Tributary Committee began funding monitoring projects from the Tributary Assessment Program in 2014, with the funding of the ONA proposal to monitor the effects of spawning platforms as adaptive management for designing and construction of more platforms. This work focused on quantifying spawners (redd surveys), egg retention (carcass surveys), egg-to-fry success, and habitat conditions (e.g., gravel stability, thalweg slope, fine sediment deposition, and gravel composition) within treated and untreated areas. Monitoring occurred throughout a 5-year period (2014 through 2018).

The Rocky Reach HCP Tributary Committee did not receive any monitoring or assessment applications in 2019.

To date, Chelan PUD has spent $53,738.14 of the original $200,000.00 total for the Rocky Reach HCP Tributary Assessment Program. The remaining balance of $146,261.86 in the Rocky Reach HCP Tributary Assessment Program is unallocated.

3 Habitat Conservation Plan Administration

This section lists events of note that occurred in 2019 related to the administration of the HCPs and provides a list of reports published in 2019 that relate to the HCPs.

3.1 Mid-Columbia Habitat Conservation Plan Forums

In 2005 and 2006, Mid-Columbia Forums were held as a means of communicating and coordinating with the non-signatories and other interested parties regarding the implementation of the HCPs. Non-signatory parties at the time of the 2006 meeting included the Confederated Tribes of the Umatilla Indian Reservation and American Rivers. As in 2006 through 2018, these parties were invited by letter in 2019 to participate in a meeting with members of the HCP Coordinating, Hatchery, and Tributary Committees, in conformity with the 2005 FERC Order on Rehearing 109 FERC 61208 and in accordance with the offer to non-signatory parties of non-voting membership in HCP Hatchery and Tributary Committees processes. The non-signatory parties again indicated no interest in attending a meeting with the HCP Committees in 2019.

3.1 Upper Columbia Salmon Recovery Board Integrated Recovery

In 2018, Douglas PUD participated in the UCSRB Hydropower Integrated Recovery Technical Advisory Group (IRTAG), along with Grant and Chelan PUDs, the YN, the CCT, and other state and federal agencies. The Hydropower IRTAG provided review and guidance in the development of the UCSRB Hydropower Background Summary as part of the UCSRB Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan's recovery strategies across all four Hs (habitat, harvest, hydropower, and hatcheries). The UCSRB Hydropower Background Summary compiles information on this management area and addresses progress in accomplishing established objectives and goals. The UCSRB presented a status update and the draft summary report during the HCP Coordinating Committees meeting on October 23, 2018. The final UCSRB Hydropower Background Summary was released on March 4, 2019 (https://www.ucsrb.org/mdocs-posts/2019-hydropower-background-summary/). There were no additional discussions within the Rocky Reach HCP Coordinating Committee on this topic in 2019.

3.2 Dispute Resolution – Basis for Decision Making

In late 2018, the HCP Tributary Committees Chairman notified the HCP Coordinating Committees of a potential impending dispute resolution from the HCP Tributary Committees (as memorialized in the minutes of the HCP Coordinating Committees meeting on December 18, 2018, and appended to the *2018 Rocky Reach HCP Annual Report*). The impetus for this arose when the HCP Tributary Committees supported funding a GSHP proposal based on its technical merit (per the criteria outlined in the *HCP Tributary Committees Policies and Procedures for Funding Projects*); however, the HCP Tributary Committees ultimately elected not to fund the project because of policy-level intervention. In early 2019, the HCP Tributary Committees and HCP Coordinating Committees continued discussing this issue and the general consensus was, if a formal dispute arises, resolution likely would not be reached in either committee. At this time, the HCP Coordinating Committees Chairman began notifying HCP Policy Committees representatives of the situation.

On May 23, 2019, the YN submitted a letter to the HCP Tributary Committees Chairman indicating the YN was formally initiating the dispute resolution process as defined in Section 11 of the Rock Island, Rocky Reach, and Wells Hydroelectric Projects Anadromous Fish Agreements and HCPs. The HCP Tributary Committees reviewed and discussed the Issue Statement; however, they could not reach resolution. Therefore, on June 10, 2019, the HCP Tributary Committees requested that the dispute proceed to the HCP Coordinating Committees. The HCP Coordinating Committees and HCP Policy Committees representatives had already been coordinating in anticipation of the dispute being elevated to the respective committees, and on June 11, 2019, the YN agreed to withdraw the formal dispute to provide flexibility in scheduling a discussion within the HCP Policy Committees without the constraints of the tight timeline of the formal dispute resolution process as outlined in the HCPs.

On July 9, 2019, the HCP Policy Committees convened an in-person meeting with three objectives: 1) have a clear exchange of thoughts, opinions, and position on the issue; 2) develop guidance for the HCP Tributary and Hatchery Committees; and 3) maintain the proper functioning and implementation of the HCPs (Appendix D). During this meeting, the HCP Policy Committees developed action items in support of all the meeting objectives. Regarding the basis for decision making, the HCP Policy Committees guidance to the HCP Tributary and Hatchery Committees was to base funding decisions on technical merit, and to notify respective HCP Coordinating and Policy Committees representatives of any potential policy issues needing to be addressed in those forums. Additionally, the HCP Tributary and Hatchery Committees should consider abstention in lieu of disapproval to preserve respective policy positions. The HCP Tributary and Hatchery Committees adopted this guidance in their respective operating protocols.

As of December 31, 2019, no additional discussions or actions had been identified as needed regarding this topic.

3.3 Mid-Columbia HCP Committees' Chairpersons

The Mid-Columbia HCPs contain a requirement to review the performance of the Chairpersons every 3 years. In August 2019, the HCP Committees were tasked with conducting such a review. The review was informal and conducted via email. HCP representatives were asked to provide input on the performance of the Chairpersons. On September 24, 2019, the HCP Coordinating Committees announced their selection to retain HCP Coordinating and Policy Committees Chairperson, Dr. John Ferguson, and support personnel, Kristi Geris, for 3 more years. On October 16, 2019, the

HCP Hatchery Committees announced their selection to retain HCP Hatchery Committees Chairperson, Dr. Tracy Hillman, and support personnel, Larissa Rohrbach, for 3 more years. On September 12, 2019, the HCP Tributary Committees announced their selection to retain HCP Tributary Committees Chairperson, Dr. Tracy Hillman, for 3 more years. The next Chairpersons review will occur in August 2022.

3.4 Habitat Conservation Plan Related Reports and Miscellaneous Documents Published in Calendar Year 2019

The following is a list of reports released in 2019 that are related to the implementation of the Rocky Reach HCP:

- Anchor QEA and Chelan PUD (Public Utility District No. 1 of Chelan County), 2019. Annual Report Calendar Year 2018 of Activities Under the Anadromous Fish Agreement and Habitat Conservation Plan Rocky Reach Hydroelectric Project FERC License No. 2145 Prepared for FERC. April 2019.
- Chelan PUD, 2019. Chelan PUD Rocky Reach and Rock Island HCPs Final 2019 Fish Spill Report. October 18, 2019.
- Chelan PUD, 2019. 2019 Rocky Reach and Rock Island HCP Action Plan – Final. February 2019.

Date: February 26, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the January 22, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, January 22, 2019, from 10:00 a.m. to 12:15 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Douglas PUD will provide edits to the revised draft December 4, 2018 HCP Coordinating Committees meeting minutes to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-B). *(Note: Tom Kahler provided Douglas PUD edits to the minutes during the HCP Coordinating Committees meeting on January 22, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*
- The HCP Coordinating Committees will provide edits or comments on Douglas PUD edits to the revised draft December 4, 2018 HCP Coordinating Committees meeting minutes to Kristi Geris no later than Friday, January 25, 2019; if no edits or comments are received, Geris will distribute the minutes as final (Item I-B). *(Note: no edits or comments were received, and the final December 4, 2018 HCP Coordinating Committees meeting minutes were distributed to the HCP Coordinating Committees by Geris on January 27, 2019.)*
- Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on passive integrated transponder (PIT)-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item I-C).
- Chelan PUD will provide a final timeline for repairing Rocky Reach Dam Turbine Unit C1 hub seals to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).
- John Ferguson will provide an update to Scott Carlon and Ritchie Graves about the impending dispute resolution from the HCP Tributary Committees (Item III-A). *(Note: Ferguson contacted Carlon and Graves on January 28, 2019, and provided updates as discussed.)*

- John Ferguson will provide an update to Scott Carlon about the Wells HCP Coordinating Committee approval of the Douglas PUD 2020 Survival Verification Study Plan, as revised (Item IV-B). *(Note: Ferguson contacted Carlon on January 28, 2019, and provided updates as discussed.)*
- The HCP Coordinating Committees meeting on February 26, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item VI-B).

Decision Summary

- The Rock Island and Rocky Reach HCP Coordinating Committees approved the 2017 Pikeminnow Report after no disapprovals were received prior to the 30-day review deadline on January 14, 2019.
- Wells HCP Coordinating Committee representatives present approved the Douglas PUD 2020 Survival Verification Study Plan, as revised (Item IV-B). *(Note: the Colville Confederated Tribes [CCT] and National Marine Fisheries Service [NMFS] approved the plan, as revised, via email on January 29, 2019.)*

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- A Wells Project Land-Use Permit Application for a Single-Use Dock (LeSage) was distributed to the HCP Coordinating Committees by Kristi Geris on November 29, 2018. This application is available for a 60-day review with edits, comments, or an indication of no comments due to Tom Kahler by Monday, January 28, 2019 (Item IV-C).
- A draft 2018 Post-Season Bypass Report and Passage-Dates Analysis was distributed to the HCP Coordinating Committees by Kristi Geris on December 14, 2018, which is available for a 60-day review with edits and comments due to Tom Kahler by Tuesday, February 12, 2019 (Item IV-F).
- A draft 2018 Wells HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on January 16, 2019, which is available for a 30-day review with edits and comments due to Tom Kahler by Friday, February 15, 2019 (Item IV-E).
- A draft *2019 Total Dissolved Gas Abatement Plan Wells Hydroelectric Project FERC Project No. 2149* was distributed to the HCP Coordinating Committees by Kristi Geris on January 21, 2019, which is available for review with edits and comments due to Douglas PUD by Monday, February 11, 2019 (Item IV-D).

- A draft 2018 Rocky Reach Juvenile Fish Bypass System Report was distributed to the HCP Coordinating Committees by Kristi Geris on January 24, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, February 25, 2019 (Item V-D).
- A draft 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report was distributed to the HCP Coordinating Committees by Kristi Geris on January 24, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, February 25, 2019 (Item V-D).
- A draft 2017 Douglas PUD Pikeminnow Removal Annual Report was distributed to the HCP Coordinating Committees by Kristi Geris on January 29, 2019, which is available for a 60-day review with edits and comments due to Tom Kahler by Thursday, March 28, 2019.
- The draft 2018 Wells HCP Annual Report was distributed to the HCP Coordinating Committees by Kristi Geris on February 5, 2019, and is available for a 30-day review with edits and comments due to Geris by Wednesday, March 6, 2019 (Item VI-A).
- A draft 2019 Rock Island and Rocky Reach HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 12, 2019, which is available for review (Item V-D).
- A draft 2019 Rock Island Bypass Monitoring Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, March 18, 2019 (Item V-D).
- A draft 2019 Rocky Reach Juvenile Fish Bypass System Operations Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, March 18, 2019 (Item V-D).
- A draft 2019 Rock Island and Rocky Reach Fish Spill Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, March 18, 2019 (Item V-D).
- The draft 2018 Rock Island and Rocky Reach HCP Annual Reports were distributed to the HCP Coordinating Committees by Kristi Geris on February 18, 2019, and are available for a 30-day review with edits and comments due to Geris by Monday, March 18, 2019 (Item VI-A).
- Columbia River Inter-Tribal Fish Commission's annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019.

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Tom Kahler added a Wells Dam fishway maintenance update
- Lance Keller added a notification of upcoming Chelan PUD documents for review
- Ferguson added a reminder about upcoming HCP annual report reviews

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft December 4, 2018 and revised draft December 18, 2018 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into both revised minutes. Geris said she also updated the Review Items in both minutes. HCP Coordinating Committees members present approved the December 18, 2018 meeting minutes, as revised. Tom Kahler said Douglas PUD has additional clarifying edits in the revised draft December 4, 2018 meeting minutes under Douglas PUD's Wells Project Land-Use Permit Applications Gebbers Farm and Repo LLC discussion and will provide these edits to Geris for distribution to the HCP Coordinating Committees. HCP Coordinating Committees members present conditionally approved the December 4, 2018 meeting minutes, contingent on accepting Douglas PUD's latest edits. The HCP Coordinating Committees will provide edits or comments on Douglas PUD edits to the revised draft December 4, 2018 HCP Coordinating Committees meeting minutes to Geris no later than Friday, January 25, 2019; if no edits or comments are received, Geris will distribute the minutes as final. *(Note: Tom Kahler provided Douglas PUD edits to the minutes during the HCP Coordinating Committees meeting on January 22, 2019, which Geris distributed to the HCP Coordinating Committees that same day. No further edits or comments were received from the HCP Coordinating Committees by the January 25, 2019 deadline, and the final December 4, 2018 HCP Coordinating Committees meeting minutes were distributed to the HCP Coordinating Committees by Geris on January 27, 2019.)*

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on December 18, 2018, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the conference call on December 18, 2018):*

- *Lance Keller will review subyearling Chinook salmon sampled at the RRJSF during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on PIT-tag detections in the bypass across the season, notably*

during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in DART (Item I-C).
This action item will be carried forward.

- *Chelan PUD will provide a final timeline for repairing Rocky Reach Dam Turbine Unit C1 hub seals to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).*
  This action item will be discussed during today's meeting and will also be carried forward.
- *Tom Kahler will determine the final outcome of the Wells Project Land-Use Permit Application for Wells Tract 115 and will report back to the HCP Coordinating Committees (Item I-C).*
  Kahler recalled this permit application was regarding an upland property that was formerly an orchard, where Douglas PUD sprays apple shoots and noxious weeds, and the landowner mows and rakes the property. Kahler said the Douglas PUD Commission approved this application.
- *On the behalf of the HCP Coordinating Committees, regarding the General Salmon Habitat Program Proposal titled, Scaffold Camp Acquisition #2 Project, which is under discussion in the HCP Tributary Committees, Keely Murdoch and Kirk Truscott will request from their respective HCP Policy representatives that a policy level discussion take place between the Yakama Nation (YN) and the CCT to reach agreement outside of the formal HCP dispute resolution process (Item II-A).*
  This action item will be discussed during today's meeting.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on January 10, 2019:

- *Project Collaboration*: Steve Kolk (U.S. Bureau of Reclamation [Reclamation]) met with the HCP Tributary Committees to describe Reclamation's vision for habitat restoration work in the upper Columbia River. Kolk discussed the evolution of restoration efforts in the upper Columbia River and concluded that efforts are now at a point where larger, more complex and expensive projects will be implemented than in the past because the easier, smaller projects have mostly been implemented. Reclamation would like to team with a funding partner and work together to identify and scope high priority projects in high priority areas. Once identified, Reclamation will use their resources to develop preliminary, draft, and final designs. Project sponsors would then be selected to implement the projects through a competitive bid process. Reclamation believes this scope-driven approach will reduce costs and increase the certainty of success. The HCP Tributary Committees see value in the process and will continue to discuss it within the HCP Tributary Committees.

- *Time Extension Request*: The Rock Island HCP Tributary Committee received a time extension request from Trout Unlimited on the Barkley Irrigation Company – Under Pressure Project. Because of the size and complexity of the project, and the time needed to complete the project, the sponsor asked to extend the completion date from December 31, 2018, to December 31, 2019. Members present from the Rock Island HCP Tributary Committee approved the time extension. Hillman will secure input from Kate Terrell (U.S. Fish and Wildlife Service [USFWS] and Justin Yeager (NMFS]) once the federal government furlough ends.
- *Icicle Creek Fish Passage – Wild Fish to Wilderness Project*: Recall in December 2018, the HCP Tributary Committees received a General Salmon Habitat Program (GSHP) proposal from Trout Unlimited titled: *Icicle Creek Fish Passage – Wild Fish to Wilderness Project*. The purpose of the project is to enhance fish passage at the Boulder Field (river mile 5.6) on Icicle Creek and thereby provide access to more than 23 miles of habitat. The total cost of the project is $2,275,000. The sponsor requested $375,000 from HCP Plan Species Account Funds. The amount requested from the HCP Tributary Committees would be in addition to the $250,000 approved by the Rock Island HCP Tributary Committee in 2015. In December 2018, all members except the CCT approved funding for the project. The CCT requested additional time before providing their vote on the project. During the HCP Tributary Committees meeting on January 10, 2019, the CCT (like the YN) approved the request with the caveat that a statement of agreement (SOA) regarding anadromous fish management in the Icicle watershed is signed by the YN, the CCT, Washington Department of Fish and Wildlife (WDFW), NMFS, and USFWS. John Ferguson asked about the status of the agreement. Jim Craig said on January 9, 2019, he and Bill Gale (USFWS Deputy Project Leader) finished drafting the Framework for Communication document and provided it to the YN (Steve Parker). Craig said on January 10, 2019, the document was also sent out to NMFS (Dale Bambrick), WDFW (Jim Brown) and the CCT (Chuck Brushwood). Craig said USFWS subsequently received emails from Parker and Brushwood with edits, but both indicated general support for the draft document. Craig also said Gale visited the Snake River Basin to better understand the Annual Operations Planning process implemented there to promote open communication and coordination between partners regarding hatchery operations. Craig said the plan is to format a similar process for the Leavenworth National Fish Hatchery and Icicle watershed. Craig said USFWS is not likely to implement the process this winter; however, USFWS will soon meet with the YN, the CCT, and WDFW to discuss operations for 2019, including predicted fish returns and potential fisheries. Ferguson asked about NMFS' thoughts, and Craig said he believes NMFS will be agreeable; however, USFWS has not yet received comments from NMFS or WDFW.
- *Upper Kahler Stream and Floodplain Enhancement Project*: Recall in December 2018, the HCP Tributary Committees received a GSHP proposal from the YN titled: *Upper Kahler Stream*

and Floodplain Enhancement Project. The purpose of the project is to reduce the risk of an avulsion near river mile 8.6 on Nason Creek by constructing a large, buried, log jam at the upstream inlet of the developing avulsion channel and filling the avulsion channel with large substrate. The project would also construct three additional buried bank jams and enhance fish habitat at the downstream end of the avulsion channel. The total cost of the project is $482,500. The sponsor requested $231,500 from HCP Plan Species Account Funds. In December 2018, the HCP Tributary Committees elected to not fund this project as currently designed but invited the project sponsor to give a presentation to the HCP Tributary Committees during a future meeting explaining the design of the project. In January 2019, the YN and their consultant provided a presentation describing the design of the proposed project. Following the presentation, the YN recused themselves and the HCP Tributary Committees discussed the project. The HCP Tributary Committees continue to struggle with filling the avulsion channel with large sediments. The HCP Tributary Committees believe adding wood and a few boulders in the avulsion channel will help trap smaller sediments and fill the channel naturally. The HCP Tributary Committees elected to table a decision on this project until Yeager and Terrell have an opportunity to provide feedback on the project.

- *Stormy Project Area "A" Stream and Floodplain Enhancement Project*: In December 2018, the HCP Tributary Committees received a GSHP proposal from the YN titled: *Stormy Project Area "A" Stream and Floodplain Enhancement Project*. The purpose of the project is to maintain salmon and steelhead spawning habitat within the middle Entiat River, improve mainstem juvenile rearing and adult holding habitat, and improve off-channel juvenile rearing habitat. The total cost of the project is $1,652,218.15. The sponsor requested $1,140,968.15 from HCP Plan Species Account Funds. In December 2018, the HCP Tributary Committees elected to not fund this project as currently designed but invited the project sponsor to give a presentation to the HCP Tributary Committees during a future meeting explaining the design of the project. In January 2019, the YN and their consultant provided a presentation on the design of the Upper Kahler Stream and Floodplain Enhancement Project. It was explained that the existing side channel the HCP Tributary Committees wanted reconnected is too high on the floodplain to connect with the river and has zero gradient in places. There would also need to be mitigation for the existing network of wetlands that currently exist in the side channel. The purpose of the large wood structures proposed along the banks of the main channel was also described. Following the presentation, the YN recused themselves and the HCP Tributary Committees discussed the project. Given the presentation and discussions, members of the HCP Tributary Committees present elected to fund the project but requested additional information regarding the costs of two items in the $1,140,968.15 budget. The HCP Tributary Committees also directed Hillman to secure feedback from Terrell and Yeager, who were not present because of the federal government furlough. If Yeager approves the project, the Rock Island or Rocky Reach Plan Species Account will support the project. Ferguson asked about Terrell's approval, and Hillman explained that USFWS is not a voting member on the HCP Tributary Committees unless Craig provides a letter indicating USFWS wants to be a voting member. Tom Kahler further explained that the HCP Tributary Committees value the input of everyone on the committees. Kahler said, for example, Douglas PUD cannot vote on projects located downstream of Wells Dam; however, Douglas PUD still participates in those discussions. Keely Murdoch asked why would USFWS not want to vote? Jim Craig said he was unaware that USFWS was not a voting member of the HCP Tributary Committees. Kahler said these voting member discussions took place during HCP negotiations when Mark Miller represented the USFWS, and Miller received input from USFWS General Counsel that USFWS did not want the liability associated with decisions made within the HCP Tributary Committees. Kahler added that USFWS not being a voting member has never been an issue. Craig said if there was an issue, he believes Terrell would have mentioned it. Craig added, however, that he will still look into obtaining a letter requesting that USFWS become a voting member on the HCP Tributary Committees. Hillman and Ferguson agreed this is a good idea. Hillman said the letter should be addressed to both himself and Ferguson indicating that USFWS would like to vote on HCP Tributary Committees decisions. Ferguson further suggested indicating in the letter that the HCP Tributary Committees reviewed the previous decision to not include USFWS as a voting member and now want to change this. Kahler read an excerpt from the meeting minutes of the HCP Tributary Committees meeting on November 24, 2004, as follows: "David Morgan (USFWS HCP Tributary Committees representative) was unable to attend this meeting but relayed to the group through Bob Bugert (HCP Tributary Committees Chairman) that USFWS will maintain its current status as non-voting representative to the Tributary Committees. Morgan said this issue can be revisited from time to time if the Committees feel there is a compelling need." *(Note: USFWS provided a letter requesting to be a voting member on the HCP Tributary Committees to Hillman and Ferguson on January 24, 2019, and Kristi Geris distributed this letter to the HCP Coordinating Committees that same day.)*

- *Johnson Creek US Highway 97 Habitat Restoration Project*: The HCP Tributary Committees received a new GHSP proposal from Trout Unlimited titled: *Johnson Creek US Highway 97 Habitat Restoration Project*. The purpose of the project is to remove a fish passage barrier on Johnson Creek, a tributary to the Okanogan River. The project will replace the existing culvert with a precast concrete structure that will allow passage for all life stages of Chinook salmon and steelhead at all flows. The project will allow fish access to 9 miles of high-quality spawning and rearing habitat in Johnson Creek. The total cost of the project is $1,562,455.00. The sponsor requested $267,547.00 from HCP Plan Species Account Funds. HCP Tributary Committees members present elected to fund the project. Chris Fisher (CCT) recused himself from voting on this project. The HCP Tributary Committees directed Hillman to secure feedback from Terrell and Yeager on this project. If approved by Yeager, the Wells Plan Species Account will support the project. Hillman added that if USFWS provides a letter requesting to be a voting member, Terrell will vote too. Ferguson said he thought there is a law which indicates the State is responsible for replacing culverts, and asked why this project came to the HCP Tributary Committees? Hillman said the State is a cost share on this project because the project was ranked as one of the highest projects by the Upper Columbia Salmon Recovery Board. Andrew Gingerich asked if Johnson Creek is an ephemeral stream? Hillman said the creek is a perennial stream that runs through the town of Riverside, Washington.

- *Review of Tributary Committees' Policies and Procedures, Policies and Procedures for Funding Projects*: The HCP Tributary Committees reviewed their Policies and Procedures document and made a minor edit to clarify language in Sections 2.0 (Funding Programs). The HCP Tributary Committees made no other edits or changes to the document.
- *Review of Tributary Committees' Policies and Procedures, Tributary Committee Operating Procedures*: The HCP Tributary Committees reviewed their operating procedures and made a formatting change to the Introduction. HCP Tributary Committees made no other edits or changes to the document.
- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on March 14, 2019. Hillman said the HCP Tributary Committees will not meet in February 2019; however, may convene a conference call to discuss any issues which might arise before March 2019.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on January 16, 2019 (*note: joint HCP Hatchery Committees/Priest Rapids Coordinating Committee [PRCC] Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Genetics Monitoring (joint)*: The HCP Hatchery Committees reviewed the responses from the panel of geneticists on how to monitor the effects of hatchery programs on genetics of natural-origin and hatchery-origin fish. The HCP Hatchery Committees were pleased with the responses from the geneticists and will update the Hatchery Monitoring and Evaluation (M&E) Plan accordingly.
- *Broodstock Collection Protocols (joint)*: The HCP Hatchery Committees discussed the preparation of the 2019 Broodstock Collection Protocols including reviewing outstanding issues identified during the preparation of the 2018 Broodstock Collection Protocols. A draft of the 2019 report will be available for HCP Hatchery Committees review by February 11, 2019, which is about 10 days before the HCP Hatchery Committees meeting on February 20, 2019.

- *Re-Evaluation of Conservation Program Size (joint)*: The HCP Hatchery Committees are looking at revising the size of the conservation programs. Importantly, total hatchery production will not change; only the allocation of production between the conservation and safety net programs may change. The HCP Hatchery Committees are currently looking to update input parameters to the spreadsheet calculator that was used during No Net Impact recalculation. Updated inputs will include spawner escapements, smolt-to-adult return data, broodstock needs, pre-spawn losses, and updated stock-recruitment estimates. Discussion on this topic will continue over the next few months.
- *Sampling of Steelhead at the Priest Rapids Dam Off-Ladder Adult Fish Trap (joint)*: WDFW reported that Bonneville Power Administration (BPA) funds will shift from developing tools to estimate steelhead escapements to developing tools to estimate spring Chinook salmon escapements. The model for estimating steelhead escapement has been fully developed and there is no need to continue working on the steelhead model. As such, steelhead PIT tagging at Priest Rapids Dam may be reduced or eliminated, and some of the PIT-tag interrogation arrays may be shut down during times when adult steelhead are moving into spawning streams. Given the reallocation in BPA funding and the desire of WDFW to use remaining funds to evaluate spring Chinook salmon escapements, the HCP Hatchery Committees will need to evaluate how to monitor steelhead escapements in the future. The HCP Hatchery Committees requested that WDFW provide to Chelan and Douglas PUDs an estimate of the cost to PIT-tag steelhead at the Priest Rapids Dam off-ladder adult fish trap and an estimate for PIT-tag array operations and maintenance.
- *Methow 2019 M&E Implementation Plan Statement of Work (Wells)*: The HCP Hatchery Committees are reviewing the Methow 2019 M&E Implementation Plan. The YN proposed general language to the plan in case WDFW and BPA funding for steelhead tagging at Priest Rapids Dam and PIT-tag array operations and maintenance is cut in 2019. Approval of the plan was tabled until members have an opportunity to study the edits made to the plan.
- *2019 Spring Chinook and Coho Salmon Final Acclimation at Chewuch Pond (Rock Island/Rocky Reach)*: Chelan PUD reported that this is the first year coho and spring Chinook salmon will be comingled in the Chewuch Pond. A total of 80,000 coho salmon will be added to the pond.
- *Tumwater Dam Update (Rock Island/Rocky Reach)*: Chelan PUD reported that there will be a slight delay in completing the reinforcement of the fishway walls at Tumwater Dam this winter. Chelan PUD expects the work to be completed by mid- to late-March 2019. This work will not affect fish passage and trapping operations at the dam.
- *Merging the HCP Hatchery Committees and PRCC Hatchery Subcommittee meetings*: The HCP Hatchery Committees agreed to merge the HCP Hatchery Committees and PRCC Hatchery Subcommittee meetings to improve efficiency, sharing, cost, and time. Although the meetings were merged, each committee maintains its independence in

identifying agenda items and decision making. The HCP Hatchery Committees and PRCC Hatchery Subcommittee identified and agreed to a structure for the agendas and meeting notes, and both committees are currently reviewing and updating their meeting protocols and distribution lists.

- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on February 20, 2019.

III. Yakama Nation

A. HCP Tributary Committees Dispute Resolution Update (Keely Murdoch)

Keely Murdoch said there is no official letter yet; however, the YN are expecting to file a dispute regarding the *Scaffold Camp Acquisition #2 Project* that has been discussed within the HCP Tributary Committees. Murdoch said a dispute will not be filed until more research is conducted to better understand what the outcome of the process will be. She said in the meantime, the YN are working to better frame the issue within the HCP Tributary Committees by presenting an SOA to the HCP Tributary Committees. She clarified that if the YN take this issue to dispute, it is not about a territorial issue between the YN and the CCT; rather, the dispute is about the basis for decision-making by the HCP Tributary Committees and the lack of guidance in voting protocols. She said she believes everyone can agree that decisions should be based on having some sort of nexus with the resource; and not be based on arbitrary reasons. She said the dispute is about the decision-making process, notably, how to make decisions.

John Ferguson asked about a timeline. Murdoch said she is uncertain about a timeline, but hopefully the YN can bring something to the HCP Tributary Committees in February 2019. Ferguson said it would be nice to have a full Committee present, i.e., not furloughed, and Murdoch agree this would be ideal.

Chad Jackson asked when funding needs to be secured for this project. Tom Kahler said funds are already available. He said there is no hang-up there because the project has technical merit. Ferguson said there is urgency about settling this issue before the landowner sells the property. Murdoch said at this point, the issue is bigger than implementing the actual project. Kahler said other individual parties have presented projects for funding in the HCP Tributary Committees similar to this project and more can be expected, so it would be good to resolve this issue now. Murdoch agreed this issue will keep arising. She said it would be beneficial if the *Scaffold Camp Acquisition #2 Project* is funded; however, this is not what the dispute is about, it is the catalyst.

Kahler said it would be nice to move forward on the *Scaffold Camp Acquisition #2 Project* regardless of the dispute. He said the YN are not gaining any sort of leverage in regard to what status this project happens to be in at the moment, and he asked if there is a workaround to move this project forward while the YN carry out the dispute. Murdoch said she can discuss this with YN policy staff.

Kahler asked what is the desired outcome of this dispute; removal of policy interference in the decision-making process? Murdoch said she needs to consult with YN policy staff but does not want to frame it as "policy interference." She said within the HCP Hatchery Committees, policy input is often times considered in the decision-making process; however, this input is related to how to manage mitigation and not about something arbitrary or unrelated.

Tracy Hillman clarified that the HCP Tributary Committees have policies and procedures in place to evaluate proposals for both the GSHP and Small Projects Program based on biological and technical merit and cost-effectiveness. Hillman said he believes what Murdoch is saying is, based on those criteria, the *Scaffold Camp Acquisition #2 Project* would clearly be funded. Hillman said, however, there is now an additional policy-level territorial criterion being used to evaluate a project. He said he believes the YN are saying this goes beyond the bounds for making decisions on proposals. He said he does not believe Murdoch is implying there should be no policy guidance; rather, policy staff should not intervene unless it is related to benefiting the project. Murdoch agreed with Hillman's comments. Kahler also agreed the HCP Tributary Committees likely would agree with these comments, but he asked still, where does this end up? Murdoch said she is unsure, but the YN are researching this now.

Ferguson said he was contacted by Steve Parker and they discussed similar questions about what the goal of this dispute is. Ferguson said he encouraged Parker to contact Hillman to discuss HCP Tributary Committees processes, which Parker did. Ferguson also let Parker know that because Parker contacted him, he also called and left a voice mail with Randy Friedlander (CCT) to discuss the pending dispute. Ferguson said, however, he has not yet heard back from Friedlander.

Ferguson said if a letter is received before the next HCP Coordinating Committees meeting on February 26, 2019, the HCP Coordinating Committees will convene via conference call to discuss the letter. Ferguson also said he will provide an update to Scott Carlon and Ritchie Graves about the impending dispute resolution from the HCP Tributary Committees. *(Note: Ferguson contacted Carlon and Graves on January 28, 2019, and provided updates as discussed.)*

IV. Douglas PUD

A. Wells Dam Fishway Maintenance Update (Tom Kahler)

Tom Kahler said the Wells Dam east fishway was dewatered for annual maintenance on January 7, and 8, 2019, as described in a memorandum distributed to the HCP Coordinating Committees by Kristi Geris on January 9, 2019. Kahler said the east fishway will be offline through the end of January 2019. He said a contractor will polish the fishway window this week. He said other work includes routine and fish pump maintenance.

B. DECISION: Douglas PUD 2020 Survival Verification Study Plan (Tom Kahler)

John Ferguson recalled discussing the study schedule at length during the last HCP Coordinating Committees meeting on December 18, 2018, and the Wells HCP Coordinating Committee generally elected a modified Option No. 2 (April 13 to May 12, extended 1 week later to end on May 19). Ferguson said Tom Kahler was tasked with discussing this option internally; and following the meeting on December 18, 2018, Kahler provided an email explaining the ultimate decision to not extend the study 7 days (Attachment B), which was distributed to the HCP Coordinating Committees by Kristi Geris on December 19, 2018. Kahler said the email (Attachment B) included an evaluation of the 2010 Survival Verification Study release replicates, which indicates that to the point whereby 75% of each release has been detected at Rocky Reach Dam requires a minimum time interval of 11 days, and the mean is 23 days. He said based on review of these data, Douglas PUD concluded a 30-day release period for the study is ideal. He said no comments on this email were received from the Wells HCP Coordinating Committee; therefore, Douglas PUD hopes to have a quick discussion and obtain approval of the study plan today.

Ferguson asked Kahler to clarify Douglas PUD's final proposed study start and stop dates. Kahler said Douglas PUD is proposing the original Option No. 2, which starts April 13 and ends May 12. Keely Murdoch said this option starts 1 week earlier than Douglas PUD's initial preferred option but does not include the 1 additional week at the end of the study. Kahler said this is correct. Chad Jackson recalled the reason to add 1 week at the end was to incorporate the tail end of each run. He asked without this additional 1 week, are there enough study fish in the system to represent the untagged fish migrating during this timeframe?

Kahler distributed hard copies of a run timing graph (Attachment C), which was also distributed electronically to the HCP Coordinating Committees by Geris following the meeting on January 22, 2019. Kahler explained that the graph (Attachment C) shows a black box representing study fish releases from April 13 to May 12, and a red hashed box encompassing a 19-day cumulative passage average from the 2010 study. He said this graph indicates that 50% of the fish released on May 12 are still in the reservoir on June 1, based on 2010 study results. He said of all releases in 2010, 87% had passed Rocky Reach Dam by May 31 and 13% of the fish were detected at Rocky Reach Dam after that date. Ferguson asked when the last release was in 2010, and Kahler said on May 17. Jackson asked about the first releases in 2010, and Kahler said 97.5% of the first releases in 2010 passed Rocky Reach Dam by May 31.

Jackson asked if Wells Fish Hatchery staff are still on track for targeting a smaller fish size, and Kahler said yes. Jackson asked if all comments were addressed in the final revised study plan (a final revised draft plan for approval was distributed to the HCP Coordinating Committees by Geris on January 15, 2019). Kahler said yes and all edits are in tracked changes. Jackson said lastly, based on the latest graph Kahler shared indicating there should be sufficient numbers of fish from all groups in the system without the additional 1 week, WDFW is supportive of the proposed Douglas PUD 2020 Survival Verification Study Plan.

Murdoch said the YN appreciates Douglas PUD moving the study forward 1 week to incorporate more coverage for wild spring Chinook salmon. She said she still believes 1 week longer would also be beneficial; however, she is okay without it if it is not feasible. Kahler noted that one effect of releasing study fish 1 week later is that when the releases are spread out and skip days, this results in fewer study fish being released during the height of the normal outmigration distribution and more fish being released on the tails of the distribution. He said it is ideal to release most of the fish during the peaks of the migration when most of the subject populations are emigrating, since the goal of the study is for the study fish to emigrate with the subject populations.

Wells HCP Coordinating Committee representatives present approved the Douglas PUD 2020 Survival Verification Study Plan, as revised.

Ferguson said he will provide an update to Scott Carlon about the Wells HCP Coordinating Committee approval of the Douglas PUD 2020 Survival Verification Study Plan, as revised. *(Note: Ferguson contacted Carlon on January 28, 2019, and provided updates as discussed.)*

Note: Immediately following the HCP Coordinating Committees meeting Kirk Truscott contacted Ferguson, who briefed Truscott on the topics covered during the meeting including the final revised Douglas PUD 2020 Survival Verification Study Plan. The CCT and NMFS approved the Douglas PUD 2020 Survival Verification Study Plan, as revised, via email on January 29, 2019.

C. Wells Project Land-Use Permit Applications (Tom Kahler)

Tom Kahler said there is one remaining Wells Project Land-Use Permit Application out for review (for a single-use dock [LeSage]), which was distributed to the HCP Coordinating Committees by Kristi Geris on November 29, 2018. This application is available for a 60-day review with edits, comments, or an indication of no comments due to Kahler by Monday, January 28, 2019. Kahler said comments or indication of no comments have been received from all Parties except NMFS (currently furloughed).

Kahler said regarding the Wells Project Land-Use Permit Applications for Gebbers Farm and Repo LLC, he asked Beau Patterson (Douglas PUD Land Use Specialist) about the expired permits. Kahler said Patterson looked into this and discovered that the landowners have already received new letters of permission from the U.S. Army Corp of Engineers (USACE) but did not provide the letters to Douglas PUD. Kahler said because USACE already released the permits, no further comment will be accepted by USACE anyway. Kahler recalled Kirk Truscott and Jim Craig mentioning plans to submit CCT and USFWS comments, respectively, to USACE; however, the comment period is no longer open.

D. 2019 Wells Dam Gas Abatement Plan and Bypass Operating Plan (Tom Kahler)

Tom Kahler said a draft *2019 Total Dissolved Gas Abatement Plan Wells Hydroelectric Project FERC Project No. 2149* was distributed to the HCP Coordinating Committees by Kristi Geris on January 21, 2019, and is available for review with edits and comments due to Douglas PUD by Monday, February 11, 2019. Douglas PUD will be requesting approval of this document during the HCP Coordinating Committees meeting on February 26, 2019. Andrew Gingerich noted that this final approved document is due to the Federal Energy Regulatory Commission by February 28, 2019.

E. 2019 Wells HCP Action Plan (Tom Kahler)

Tom Kahler said a draft 2018 Wells HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on January 16, 2019, which is available for a 30-day review with edits and comments due to Kahler by Friday, February 15, 2019.

F. 2018 Wells Dam Post-Season Bypass Report and Passage-Dates Analysis (Tom Kahler)

Tom Kahler said a draft 2018 Post-Season Bypass Report and Passage-Dates Analysis was distributed to the HCP Coordinating Committees by Kristi Geris on December 14, 2018, which is available for a 60-day review with edits and comments due to Kahler by Tuesday, February 12, 2019. Kahler said he received comments from Jim Craig prior to today's meeting on January 22, 2019.

V. Chelan PUD

A. Rocky Reach and Rock Island Adult Fishway Maintenance Updates (Lance Keller)

Lance Keller reviewed adult fishway maintenance updates at Rocky Reach Dam and Rock Island Dam, as follows:

<u>Rocky Reach Dam</u>

Keller said the upper adult fishway at Rocky Reach Dam was taken offline for annual winter maintenance on January 2, 2019. He said headgates were installed at the exits allowing the upper fishway to drain down to an elevation equal to the tailwater, and a fish rescue was performed that same day. He said fish rescued included:

Species	Stage/Length	Clip	Count
Pacific lamprey (*Entosphenus tridentatus*)	Adult	Not Applicable	54
Whitefish (*Coregonus clupeaformis*)	Not Reported	Not Applicable	25
Rainbow/steelhead (*Oncorhynchus mykiss*)	1 fish within 12- to 18-inches	Ad-present	10
	Not Reported	Ad-clipped	2

Keller recalled that last year, the number of Pacific lamprey encountered was in the triple digits. He also noted that one adipose (ad)-present *Oncorhynchus mykiss* encountered was within the 12- to 18-inch range in length; however, it had no coded wire tag (CWT) so crews released the fish. He said he later discovered that WDFW is interested in all *Oncorhynchus mykiss* within the 12- to 18-inch range in length regardless of tag presence. Chad Jackson said this is correct because origin can also be determined based on the fish scale pattern.

Keller said the area between the count window and exit was dewatered on January 4, 2019, and a fish rescue was performed that same day. He said fish rescued included:

Species	Stage/Length	Clip	Count
Rainbow/steelhead	Not Reported	Ad-present	8
	1 fish within 12- to 18-inches	Ad-clipped	4
Coho salmon (*Oncorhynchus kisutch*)	Juvenile	Not Applicable	1
Whitefish	Not Reported	Not Applicable	1
Chiselmouth (*Acrocheilus alutaceus*)	Not Reported	Not Applicable	2
Shiner (*Notropis hudsonius*)	Not Reported	Not Applicable	8

Keller said one ad-clipped *Oncorhynchus mykiss* was within the 12- to 18-inch range in length and was turned over to Mike Tonseth (WDFW).

Keller said the lower adult fishway at Rocky Reach Dam was taken offline for annual winter maintenance on January 8, 2019, and a fish rescue was performed that same day. He said fish rescued included:

Species	Stage/Length	Clip	Count
Pacific lamprey	Adult	Not Applicable	11
Steelhead	Adult	Ad-clipped	1
Triploid rainbow	Not Reported	Ad-clipped	5
Cutthroat (*Oncorhynchus clarkii*)	Not Reported	Not Applicable	1
Rainbow/steelhead	3 fish within 12- to 18-inches	Ad-present	9
	5 fish within 12- to 18-inches	Ad-clipped	6
Whitefish	Not Reported	Not Applicable	38
Shiner	Not Reported	Not Applicable	14
Chiselmouth	Not Reported	Not Applicable	4
Peamouth (*Mylocheilus caurinus*)	Not Reported	Not Applicable	6
Sucker (*Catostomus commersonii*)	Not Reported	Not Applicable	1
Pikeminnow (*Ptychocheilus oregonensis*)	Not Reported	Not Applicable	2

Keller noted that during the days leading up to the lower ladder dewatering, all fishway entrances were left open, allowing fish to move out of the ladder on their own volition. He said the triploid rainbows were all big, plump fish. He said three ad-present *Oncorhynchus mykiss* were within the 12- to 18-inch range in length; however, these fish had no CWT, so crews released the fish. He said five ad-clipped *Oncorhynchus mykiss* were within the 12- to 18-inch range in length, which were turned over to Tonseth.

Rock Island Dam

Keller said currently, the right and left adult fish ladders at Rock Island Dam are offline for annual winter maintenance. He said the inspection of the left ladder is nearly complete, and Biomark is still investigating the noise issue in the PIT-tag detector in the right ladder. He said the center ladder is still watered up and is scheduled to be taken offline for maintenance on January 28, 2019 (after the left ladder is returned to service). He said a fish rescue in the center ladder will take place the same day as dewatering. He said the left adult fish ladder was dewatered on January 7, 2019, and a fish rescue was conducted that same day. He said fish rescued included:

Species	Stage/Length	Clip	Count
Rainbow/steelhead	Not Reported	Ad-present	8
	1 fish within 12- to 18-inches	Ad-clipped	5
Sucker	Not Reported	Not Applicable	1

Keller said one ad-clipped *Oncorhynchus mykiss* was within the 12- to 18-inch range in length; however, had no CWT so crews released the fish.

Keller said after Biomark completes their noise investigation in the right adult fish ladder, the ladder will be returned to service by the end of February 2019.

B. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said Rock Island Dam mechanics are progressing well with disassembling Turbine Unit B4. Keller said return-to-service date for Turbine Unit B4 is still July 2019. He said mechanical staff are continually evaluating all components of the turbines to understand what needs to be refurbished and replaced. He said the priority is the small units. He recalled reporting during the last HCP Coordinating Committees meeting on December 18, 2018, that the rotor has been removed from Turbine Unit B4 and the turbine and hub will come out shortly.

C. Rocky Reach Dam Turbine Unit C1 Update (Lance Keller)

Lance Keller said disassembly of Turbine Unit C1 to replace the trunnion bushing will begin in mid-February 2019. Keller said there is a slight time delay due to a shortage of headgates. He said all headgates required to remove another unit from service are in use for blade block inspections and fishway maintenance. He said once the adult fish ladder is returned to service in mid-February 2019, these gates will become available for Turbine Unit C1. He said the unfortunate part about starting disassembly of Turbine Unit C1 in mid-February 2019, is that the planned outage is 6 months, which lasts into mid-August 2019. He said, therefore, it can be expected that in 2019 operation of Turbine Unit C1 will be similar to 2018 and it will not be operated for the duration of the juvenile fish bypass season, which runs from April 1 to August 31, 2019. He said Rocky Reach Dam bypass operations in 2019 will include: 1) using three additional Rocky Reach Juvenile Fish Bypass System Surface Collector (RRJFBS SC) pumps to increase attraction flow from 6,000 to 6,660 cubic feet per second (cfs) into the RRJFBS SC entrances (3,330 cfs on each side); and 2) increasing Turbine Unit C2 flow from its normal soft-limit set-point of 12,200 cfs (12.2 kcfs) to a soft-limit flow of 15.2 kcfs.

Keller said these modified operations for the RRJFBS SC and Turbine Unit C2 will be appended to the 2019 Rocky Reach Juvenile Fish Bypass System Operations Plan.

D. Upcoming Chelan PUD Documents for Review (Lance Keller)

Lance Keller notified the Rock Island and Rocky Reach HCP Coordinating Committees that a number of documents will be distributed for review shortly, including a draft 2019 RRJFBS Operations Plan, draft 2019 Rock Island Dam Smolt Monitoring and Gas Bubble Trauma Evaluation Plan, draft 2019 Rock Island and Rocky Reach HCP Action Plan, and draft 2019 Rock Island and Rocky Reach Dams Fish Spill Plan.

A draft 2018 RRJFBS Report and draft 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report were distributed to the HCP Coordinating Committees by Kristi Geris on January 24, 2019, which are available for a 32-day review with edits and comments due to Keller by Monday, February 25, 2019.

A draft 2019 Rock Island and Rocky Reach HCP Action Plan was distributed to the HCP Coordinating Committees by Geris on February 12, 2019, which is available for review.

A draft 2019 Rock Island Bypass Monitoring Plan, draft 2019 RRJFBS Operations Plan, and draft 2019 Rock Island and Rocky Reach Fish Spill Plan were distributed to the HCP Coordinating Committees by Geris on February 15, 2019, which are available for a 32-day review with edits and comments due to Keller by Monday, March 18, 2019.

VI. HCP Administration

A. 2018 HCP Annual Reports (John Ferguson)

John Ferguson reminded the HCP Coordinating Committees of upcoming review timelines for the 2018 HCP Annual Reports, as follows:

- 2018 Wells HCP Annual Report due to the Wells HCP Coordinating Committee for a 30-day review on Wednesday, February 6, 2019
- 2018 Rock Island and Rocky Reach HCP Annual Reports due to the Rock Island and Rocky Reach HCP Coordinating Committees for a 30-day review on Monday, February 18, 2019

Ferguson suggested that HCP Coordinating Committees representatives coordinate accordingly with their respective HCP Hatchery and Tributary Committees representatives for adequate review of these reports.

The draft 2018 Wells HCP Annual Report was distributed to the HCP Coordinating Committees by Kristi Geris on February 5, 2019, and is available for a 30-day review with edits and comments due to Geris by Wednesday, March 6, 2019.

The draft 2018 Rock Island and Rocky Reach HCP Annual Reports were distributed to the HCP Coordinating Committees by Geris on February 18, 2019, and are available for a 30-day review with edits and comments due to Geris by Monday, March 18, 2019.

B. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on February 26, 2019, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The March 26, and April 23, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

Subject:	FW: Extending the study to 37 days
Date:	Wednesday, December 19, 2018 08:40:26 AM
Attachments:	image002.png image006.png

Hi HCP-CC: please see the email below from Tom regarding extending the Douglas PUD 2020 SVS to 37 days.

The email below is also available for download from the HCP Coordinating Committees Extranet Site, under: Draft Documents > All by Mtg Date > 1/22/2019 (instructions below). Thanks! – kristi

Instructions:

To gain access to the HCP Coordinating Committees Extranet Homepage, please use the following procedure:

* Visit: https://extranet.dcpud.net/sites/nr/hcpcc/
* Login using "Forms Authentication" (for non-Douglas PUD employees)

You should now be at the HCP CC homepage.

If you encounter problems, or need a login username and password to access the site:
Please feel free to contact me or Julene McGregor [jmcgregor@dcpud.org; (509) 881-2236] and we will gladly assist you with questions or issues.

Kristi Geris

Subject: Extending the study to 37 days

Hi Kristi,

Please distribute this to the CC.

Thanks,

Tom

In thinking about the CC's interest in extending the study beyond 30 days to 37 days, I went back and looked at the Methow releases during the 2010 SVS to see how the passage distributions from each release compared with the release dates. The chart below the table shows the cumulative RRJ detection dates for each release as cumulative percentages. The now-familiar box encompasses the release period for all replicates (minus the first two days because of travel times to first detections from the 4/19 release). Contrary to what I recall, the first release moved rather rapidly, but stalled out for the final 20% of the release. However, that's not the point of this message.

Please note that for every release, the passage distribution extends over a month (see chart). In fact, to the point of 50% passage for each release, the minimum time interval is 9 days and the mean is 19 days, and to 75% passage the minimum is 11 days and the mean 23 days (see table below). Therefore the repeated releases are flooding the river with tagged study fish, and the effect of multiple releases extends well beyond the final release date. The take-home point, is that I see no need to add 7 days to the release schedule to encompass greater percentages of the runs of the respective stocks. The passage distributions for each release effectively add that desired bonus coverage.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: March 26, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the February 26, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, February 26, 2019, from 10:00 to 11:30 a.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on passive integrated transponder (PIT)-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item I-C).
- Chelan PUD will provide a final timeline for repairing Rocky Reach Dam Turbine Unit C1 hub seals to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).
- Tom Kahler will revise the draft 2018 Wells HCP Action Plan, as discussed, and will provide a final plan to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-A). *(Note: Kahler provided the final plan to Geris following the meeting on February 26, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Lance Keller will determine whether the weir box within the intake of Turbine Unit C1 was fixed to facilitate river flow through this area of the Intake Screen System with Turbine Unit C1 out of service during the 2019 bypass season (Item IV-A).
- Lance Keller will inquire internally about the reasoning behind taking downstream-migrating Pacific Lamprey at the Rocky Reach Juvenile Fish Bypass System (RRJFBS) and releasing these fish at an upstream location (Item IV-A).
- The HCP Coordinating Committees meeting on March 26, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item V-C).

Decision Summary

- Wells HCP Coordinating Committee representatives present approved the 2018 Wells HCP Action Plan, as revised (Item III-A). *(Note: Chad Jackson provided Washington Department of Fish and Wildlife's [WDFW's] approval of the plan via email on February 27, 2019.)*
- Wells HCP Coordinating Committee representatives present approved the 2018 Post-Season Bypass Report and Passage-Dates Analysis (Item III-B).
- Wells HCP Coordinating Committee representatives present approved the *2019 Total Dissolved Gas Abatement Plan Wells Hydroelectric Project FERC Project No. 2149* (Item III-C). *(Note: Chad Jackson provided WDFW's approval of the plan via email on February 27, 2019.)*
- Rocky Reach HCP Coordinating Committee representatives present approved the 2018 RRJFBS Report (Item IV-A).
- Rock Island HCP Coordinating Committee representatives present approved the 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report (Item IV-B).
- The 2018 Wells HCP Annual Report was approved by the Wells HCP Coordinating Committee on March 22, 2019, after no disapprovals were received prior to the 37-day review period deadline and edits and comments received on the report were addressed and approved by the Colville Confederated Tribes (Item V-B).
- The 2018 Rock Island and Rocky Reach HCP Annual Reports were approved by the Rock Island and Rocky Reach HCP Coordinating Committees after no disapprovals were received prior to the 30-day review period deadline on March 18, 2019 (Item V-B).

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- A draft 2017 Douglas PUD Pikeminnow Removal Annual Report was distributed to the HCP Coordinating Committees by Kristi Geris on January 29, 2019, which is available for a 60-day review with edits and comments due to Tom Kahler by Thursday, March 28, 2019.
- A draft 2019 Rock Island and Rocky Reach HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 12, 2019, which is available for a 30-day review with edits and comments due to Lance Keller by Thursday, March 14, 2019 (Item IV-G).
- A draft 2019 Rock Island Bypass Monitoring Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, March 18, 2019 (Item IV-H).

- A draft 2019 RRJFBS Operations Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, March 18, 2019 (Item IV-H).
- A draft 2019 Rock Island and Rocky Reach Fish Spill Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, which is available for a 32-day review with edits and comments due to Lance Keller by Monday, March 18, 2019 (Item IV-I).
- Columbia River Inter-Tribal Fish Commission's (CRITFC's) annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019 (Item III-E).
- The HCP Hatchery Committees and Priest Rapids Coordinating Committee (PRCC) Hatchery Subcommittee-approved 2019 Broodstock Collection Protocols were distributed to the HCP Coordinating Committees by Kristi Geris on March 23, 2019.

Finalized Documents

- The final 2018 Wells HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 26, 2019 (Item III-A).
- The final *2019 Total Dissolved Gas Abatement Plan Wells Hydroelectric Project FERC Project No. 2149* was distributed to the HCP Coordinating Committees by Kristi Geris on March 2, 2019 (Item III-C).
- The final 2018 Wells HCP Annual Report was distributed to the HCP Coordinating Committees by Kristi Geris on March 25, 2019 (Item V-B).

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. Tom Kahler added CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft January 22, 2019 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. Geris said she also updated the Review Items, as additional items were distributed for review. Lance Keller said Chelan PUD has one additional edit regarding Sampling of Steelhead at the Priest Rapids Dam Off-Ladder Adult Fish Trap under the HCP Hatchery Committees Update. Keller clarified that given the "reallocation" (not "reduction") in BPA funding and the desire of WDFW to use remaining funds to evaluate spring Chinook salmon escapements, the HCP Hatchery Committees will need to evaluate how to monitor steelhead escapements in the future. HCP Coordinating Committees members present approved the January 22, 2019 meeting minutes, as revised. National Marine Fisheries Service (NMFS) abstained, because a NMFS representative was not present during the January 22, 2019 meeting.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on January 22, 2019, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on January 22, 2019):*

- *Douglas PUD will provide edits to the revised draft December 4, 2018 HCP Coordinating Committees meeting minutes to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-B).*
  Tom Kahler provided Douglas PUD edits to the minutes during the HCP Coordinating Committees meeting on January 22, 2019, which Geris distributed to the HCP Coordinating Committees that same day.
- *The HCP Coordinating Committees will provide edits or comments on Douglas PUD edits to the revised draft December 4, 2018 HCP Coordinating Committees meeting minutes to Kristi Geris no later than Friday, January 25, 2019; if no edits or comments are received, Geris will distribute the minutes as final (Item I-B).*
  No edits or comments were received, and the final December 4, 2018 HCP Coordinating Committees meeting minutes were distributed to the HCP Coordinating Committees by Geris on January 27, 2019.
- *Lance Keller will review subyearling Chinook salmon sampled at the RRJSF during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on PIT-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in DART (Item I-C).*
  This action item will be carried forward.
- *Chelan PUD will provide a final timeline for repairing Rocky Reach Dam Turbine Unit C1 hub seals to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).*
  This will be discussed during today's meeting and will also be carried forward.
- *John Ferguson will provide an update to Scott Carlon and Ritchie Graves about the impending dispute resolution from the HCP Tributary Committees (Item III-A).*
  Ferguson contacted Carlon and Graves on January 28, 2019, and provided updates as discussed.

- *John Ferguson will provide an update to Scott Carlon about the Wells HCP Coordinating Committee approval of the Douglas PUD 2020 Survival Verification Study Plan, as revised (Item IV-B).*
  Ferguson contacted Carlon on January 28, 2019, and provided updates as discussed.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman reported that the HCP Tributary Committees did not meet in February 2019 and will next meet on March 14, 2019. Hillman said the Yakama Nation (YN) provided a draft Statement of Agreement (SOA) titled, "Basis for Decision Making in HCP Tributary Committees," to the HCP Tributary Committees on February 25, 2019, which will be discussed during the HCP Tributary Committees meeting on March 14, 2019. John Ferguson asked what happens if the SOA is not approved? Keely Murdoch described two potential outcomes: 1) the YN takes no further action; or 2) the YN takes the SOA to dispute resolution. Murdoch added that the HCP Tributary Committees could approve the SOA with edits. Lance Keller said historically, the HCP Coordinating Committees have been effective in discussing, compromising, and editing SOAs until approved. Tom Kahler agreed this has been the pattern within the HCP Hatchery Committees, as well.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on February 20, 2019 (*note: joint HCP Hatchery Committees/PRCC Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Broodstock Collection Protocols (joint)*: The 2019 Broodstock Collection Protocols are under review. Comments on the protocols are due to WDFW by March 1, 2019. There will be a conference call on March 11, 2019, to address any outstanding issues. WDFW will request approval of the protocols during the HCP Hatchery Committees meeting on March 20, 2019.
- *NMFS Consultation (joint)*: Consultation fell behind due to the government furlough. NMFS is completing the Draft Environmental Assessments for Upper Columbia River Steelhead and Summer/Fall Chinook Salmon Programs. These will soon be available for public review. Permits for the unlisted Chinook salmon programs are under review by the General Council.
- *Methow 2019 Monitoring and Evaluation Implementation Plan Statement of Work (SOW; Wells)*: The Wells HCP Hatchery Committee is reviewing the Methow 2019 Monitoring and Evaluation Implementation Plan SOW. Possible language changes to the SOW addressing estimation of steelhead escapements are being discussed in the event that WDFW/Bonneville Power

Administration funding for steelhead tagging at Priest Rapids Dam and PIT-tag array operations and maintenance funding is cut in 2019.

- *2019 Wells HCP Action Plan (Wells)*: The Wells HCP Hatchery Committee reviewed the 2019 Wells HCP Action Plan. The Wells HCP Hatchery Committee (and Wells HCP Tributary Committee) expressed no edits or concerns with the plan, which is now ready for Wells HCP Coordinating Committee approval.
- *Job Opening (Wells)*: Douglas PUD has an opening for a Hatchery Specialist.
- *2019 Rock Island and Rocky Reach HCP Action Plan (Rock Island/Rocky Reach)*: The Rock Island and Rocky Reach HCP Hatchery Committees (and Rock Island and Rocky Reach HCP Tributary Committees) are currently reviewing the 2019 Rock Island and Rocky Reach HCP Action Plan. Comments are due to Chelan PUD by March 11, 2019.
- *Tumwater Dam Update (Rock Island/Rocky Reach)*: Recall in 2018, adult Pacific lamprey surveys conducted at Tumwater Dam documented erosion of the fishway pad. A private contractor conducted core sampling, analyzed the samples, and determined erosion of the fishway pad is not as bad as originally thought. Therefore, there will be no reinforcement work to the fishway in 2019.
- *Joint Meetings of the HCP Hatchery Committees and PRCC Hatchery Subcommittee*: The HCP Hatchery Committees and PRCC Hatchery Subcommittee now have the same Chairperson. Therefore, the HCP Hatchery Committees and PRCC Hatchery Subcommittee are currently reviewing and updating the meeting protocols and distribution lists. Hillman noted that the PRCC Hatchery Subcommittee email distribution list may include individuals not already included on the HCP email lists and HCP Coordinating Committees representatives may be bringing these individuals to the HCP Coordinating Committees for approval.
- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on March 11, 2019 (conference call) and March 20, 2019 (regular monthly meeting).

III. Douglas PUD

A. DECISION: 2019 Wells HCP Action Plan (Tom Kahler)

Tom Kahler said a draft 2018 Wells HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on January 16, 2019. The action plan was available for a 30-day review with edits and comments due to Kahler by Friday, February 15, 2019.

Kahler said under the Wells HCP Hatchery Committee section, "Annual Implementation – Okanagan Sockeye Fish/Water Management Tools" (Item No. 5) was expanded to include six additional bullets describing the timing of various tasks. He said the HCP Hatchery Committees were notified of these changes.

Kahler said under the Wells HCP Coordinating Committee section, the "Fishway Outage Schedule for Fishway Inspection, Maintenance, and Fishway Projects" action indicates incorrect dates, which will be corrected in the final plan.

Wells HCP Coordinating Committee representatives present approved the 2018 Wells HCP Action Plan, as revised. *(Note: Chad Jackson provided WDFW's approval of the plan via email on February 27, 2019.)*

Kahler will revise the draft 2018 Wells HCP Action Plan, as discussed, and will provide a final plan to Geris for distribution to the HCP Coordinating Committees. *(Note: Kahler provided the final plan to Geris following the meeting on February 26, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*

B. DECISION: 2018 Wells Dam Post-Season Bypass Report and Passage-Dates Analysis (Tom Kahler)

Tom Kahler said a draft 2018 Post-Season Bypass Report and Passage-Dates Analysis was distributed to the HCP Coordinating Committees by Kristi Geris on December 14, 2018, which was available for a 60-day review with edits and comments due to Kahler by Tuesday, February 12, 2019. Kahler said the only comment received was an indication of no comment from Jim Craig prior to today's meeting on January 22, 2019.

Wells HCP Coordinating Committee representatives present approved the 2018 Post-Season Bypass Report and Passage-Dates Analysis.

C. DECISION: 2019 Wells Dam Gas Abatement Plan (Tom Kahler)

Tom Kahler said a draft *2019 Total Dissolved Gas Abatement Plan Wells Hydroelectric Project FERC Project No. 2149* was distributed to the HCP Coordinating Committees by Kristi Geris on January 21, 2019, and this final approved document is due to the Federal Energy Regulatory Commission (FERC) by February 28, 2019. Kahler said the Aquatic Settlement Work Group (SWG) and Washington Department of Ecology already approved the document on February 20, 2019. Andrew Gingerich noted that WDFW also already approved the document within the Aquatic SWG. Kahler said no comments were received from the Wells HCP Coordinating Committee.

Kirk Truscott requested for documents similar to this one where there are minimal changes year-to-year, that a redline version be provided to showcase what changed. Gingerich agreed a redline version would be easy to share. He said since the initial revisions in the first years of Douglas PUD's Clean Water Act Section 401 Water Quality Certification, the Plan has remained largely the same document. He said the 2019 plan includes installing forebay temperature sensors to help decrease forced spill events and also continues concentrating spill through Spillway 7.

Truscott recalled language in the draft plan about Douglas PUD's ability to spill for fish passage at times determined by incoming flow and total dissolved gas received from Chief Joseph and Grand Coulee dams as primarily a function of peak flows above the 7-day, 10-year-frequency (7Q10) flow at Wells Dam. Truscott said if this is the case, how often can Douglas PUD not spill for fish passage when there is no flow exceedance, and is this a regular issue? Gingerich said regardless of incoming flow and total dissolved gas at Wells Dam, bypass operations during the fish passage season trump total dissolved gas standard requirements (i.e., fish passage standards will not be deferred, and Douglas PUD will accept total dissolved gas violations to facilitate bypass at Wells Dam). John Ferguson said Douglas PUD has also paid Project Participants (customers) to take power from Wells Dam to help facilitate bypass operations and control total dissolved gas.

Wells HCP Coordinating Committee representatives present approved the *2019 Total Dissolved Gas Abatement Plan Wells Hydroelectric Project FERC Project No. 2149*. *(Note: Chad Jackson provided WDFW's approval of the plan via email on February 27, 2019.)*

The final *2019 Total Dissolved Gas Abatement Plan Wells Hydroelectric Project FERC Project No. 2149* was distributed to the HCP Coordinating Committees by Geris on March 2, 2019.

D. Wells Dam Fishway Maintenance Update (Tom Kahler)

Tom Kahler recalled reporting during the last HCP Coordinating Committees meeting on January 26, 2019, that the Wells Dam east fishway was dewatered for annual maintenance on January 7, 2019. Kahler said the east fishway was back in service by February 5, 2019. He said the west fishway was dewatered for annual maintenance on February 12, 2019, and should be back online by March 1, 2019. Kahler said east and west ladder fish salvage memorandums were distributed to the HCP Coordinating Committees by Kristi Geris on January 9 and February 15, 2019, respectively. *(Note: As of March 18, 2019, the west fishway remains out-of-service while mechanics work on improvements to the trapping infrastructure at Pool 40.)*

Kahler said west fishway maintenance activities included improvements to aid Pacific lamprey passage (i.e., closing diffuser grating gaps), which the Aquatic SWG was able to tour. Kahler said the background behind the count windows was painted and the windows were polished. He said damaged brushes designed to prevent fish from accessing certain areas through the fishway were also replaced.

E. CRITFC's Annual Request to Tag Sockeye Salmon at Wells Dam in 2019 (Tom Kahler)

Tom Kahler said CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019. Kahler said Douglas PUD will request approval during the HCP Coordinating Committees meeting on March 26, 2019.

IV. Chelan PUD

A. DECISION: 2018 RRJFBS Report

Lance Keller said a draft 2018 RRJFBS Report was distributed to the HCP Coordinating Committees by Kristi Geris on January 24, 2019, which was available for a 32-day review with edits and comments due to Keller by Monday, February 25, 2019. Keller said Jim Craig distributed USFWS comments on the draft report to the HCP Coordinating Committees prior to the meeting on February 26, 2019. Keller reviewed USFWS comments, as follows:

Comment 1: Overview of 2018 RRJFBS Operations (page 3 of the draft report) describes maintenance of the associated screens and trash racks, including "when high differentials were observed at the trashracks in Unit 2, an outage period of 5 to 6 hours was usually required for divers to manually remove debris from the trashracks." How often did this occur during the sampling season?

Keller said this varies year-to-year and timing depends on debris loading and river flow. He said outages are initiated when there is a 2- to 3-foot differential across the trash racks and are conducted in the early hours of the day to avoids impacts to juvenile monitoring, which is also a safer timeframe for divers to conduct the work.

Comment 2: Observational comment.

Comment 3: Figure 2 (page 11 of the draft report) is really hard to read. Suggest updating to make consistent with Figure 2 in the draft 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report.

Keller said this will be addressed in the 2019 report.

Comment 4: Observational comment.

Comment 5: In Appendix A (Collection flows in the RRJFBS April 1 to August 31, 2018), why did the flows through the Intake Screen System, which had been largely consistent at approximately 120 cubic feet per second (cfs) since the second week in April 2018, suddenly reduce to 60 cfs on May 23, 2018? These reduced flows (52 to 60 cfs) stayed this way until sampling ended on August 31, 2018.

Keller explained that the intake screens in Turbine Unit C1 and Turbine Unit C2 include three weir slots per unit, and each is equipped with two valves that provide 10 cfs of water each through the respective slots. He said with Turbine Unit C1 offline for maintenance, there were issues with isolating Turbine Unit C1 and providing water to all areas of the Intake Screen System. He said he is unsure whether this has been addressed for the 2019 bypass season; however, he noted that this does not affect collection efficiency of fish in Turbine Unit C2 because the systems merge after a conduit system. He said he will determine whether the weir box within the intake of Turbine Unit C1 was fixed to facilitate river flow through this area of the Intake Screen System with Turbine Unit C1 out of service during the 2019 bypass season.

Kirk Truscott said he will provide Colville Confederated Tribes comments for consideration in the 2019 report. He said one comment is regarding how well the specified primary collection period corresponds to when subyearlings are actually passing Rocky Reach Dam. Keller said this question is related to an outstanding Chelan PUD action item. He said he has discussed this question internally with Steve Hemstrom who has previously discussed the question with Dr. John Skalski (Columbia Basin Research) and determined as long as the index samples are conducted at the same time each year, the run-timing forecast is applicable (i.e., regarding spill protection dates there is no statistical concern).

Truscott said another comment is regarding the 46 adult Pacific lamprey that were migrating downstream but were collected at the RRJFBS and relocated upstream at Lincoln Rock State Park. He asked, why relocate downstream-migrating fish upstream? Keller said will inquire internally about this reasoning.

Rocky Reach HCP Coordinating Committee representatives present approved the 2018 RRJFBS Report.

B. DECISION: 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report

Lance Keller said a draft 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report was distributed to the HCP Coordinating Committees by Kristi Geris on January 24, 2019, which was available for a 32-day review with edits and comments due to Keller by Monday, February 25, 2019. Keller said Jim Craig distributed USFWS comments on the draft report to the HCP Coordinating Committees on February 25, 2019. Keller reviewed USFWS comments, as follows:

Comment 1: The 2016-2017 pilot study results indicate holding of fish in the 4.4 cubic meter raceway up to 24 hours significantly increased evidence of gas bubble trauma (GBT). Any idea why?

Keller explained that fish with high levels of gas in the bloodstream compensate by migrating deeper in the water column. He said when fish are collected for GBT monitoring using the "traditional" method, samples are held in the shallower depths of the collection raceway for up to 24 hours before being observed for signs of GBT, which is forcing the gas out of the bloodstream. He is fairly confident this is the cause for the higher levels of observed GBT expression. He said it is Chelan PUD's goal to collect fish directly from the dewatering screens for GBT monitoring, which they have labeled the "fresh" fish collection method. This seems to be a truer reflection of GBT expression in run of the river fish. He said, however, using the latter method is difficult because the Fish Passage Center (FPC) requests a sample size of 75 to 100 fish (with 100 being ideal), creating time and staffing limitations. He said Chelan PUD has requested additional funding through the FPC Smolt Monitoring Program

(SMP) in order to collect the entire sample using the fresh fish collection method. Craig suggested clarifying this in future reports, as needed.

Keely Murdoch agreed with Keller's comments. She said it would be beneficial if there was a deeper holding area at Rock Island Dam; however, recognized this could be difficult and expensive given the site constraints. Keller agreed creating a deeper area would be a logistical challenge due to the location.

Keller said GBT monitoring is conducted twice per week and monitoring involves investigation of the eyes, paired fins, and caudal fin. He said the lateral line is no longer included in GBT monitoring. John Ferguson said a change in the protocol occurred in 2002 when inspection of the lateral line was removed from the protocol.

Kirk Truscott asked about reporting monitoring of fresh versus traditional fish, and Keller said these fish are reported separately. Keller said crews are encouraged to conduct as many fresh fish collections as possible and the remainder of the sample is comprised of fish collected in the traditional method, which is included in the 2019 Rock Island Bypass Monitoring Plan. Truscott asked if GBT monitoring is conducted on subyearlings, and Keller said monitoring is conducted on both yearling and subyearling Chinook salmon.

Comment 2: Unclear and inconsistent fish origin classifications (examples provided in the original email).

Keller said the nomenclature comes from FPC SMP. He said the SMP protocols stipulate classifying Chinook salmon as clipped or unclipped and steelhead as hatchery or wild, using an additional evaluation of "eroded fin" to help identify an adipose-present hatchery steelhead. Keller said Chelan PUD follows FPC SMP protocols because Chelan PUD receives funding from FPC SMP to conduct GBT monitoring.

Comment 3: In Table 5 (page 7 of the draft report), why do you think subyearling Chinook salmon had nearly double the injury rate and a 5.5-times higher mortality rate compared to yearling Chinook salmon at the Rock Island Dam Juvenile Sampling Facility? Sockeye salmon injury and mortality are also higher than yearling Chinook salmon and steelhead. Is there an issue with the 4.4 cubic meter raceway/holding tank or somewhere else in the conveyance? Is this a density issue?

Keller said he attributes the increase in injury and mortality rates to the prevalence of fry. He said FPC SMP protocol combine clipped and unclipped fry with subyearlings. He said the majority of mortalities are fry, and are largely due to fry being impinged, eaten by another fish and spit back out, and water temperatures. Truscott asked if less than 75 millimeters is considered a fry, and Keller said this is correct. *(Note: Keller later corrected himself and clarified fry are Chinook, coho, or sockeye salmon equal to or less than 60 millimeters.)*

Comment 4: Add a footnote to Table 7 (page 8 of the draft report) to denote the AP, AB, AS, and MP column headings[1].

Keller said this can be done.

Comment 5: Similar comment to Comment 1, which was addressed.

Comment 6: Observational comment.

Rock Island HCP Coordinating Committee representatives present approved the 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report.

C. Rocky Reach and Rock Island Adult Fishway Maintenance Updates (Lance Keller)

Lance Keller reviewed adult fishway maintenance updates at Rocky Reach Dam and Rock Island Dam, as follows:

Rocky Reach Dam

Keller said the adult fishway at Rocky Reach Dam was returned to service on February 15, 2019. He said this was made possible because: 1) there was a minimal maintenance list for the fishway this year; and 2) mechanical crews wanted to start disassembly of Turbine Unit C1 to replace the trunnion bushing, and the headgates required to remove another unit from service were in use for the fishway maintenance.

Rock Island Dam

Keller said the left adult fish ladder was returned to service on January 26, 2019.

Keller said the right adult fish ladder is still out-of-service and Biomark is wrapping up installation of an additional PIT-tag array, which will boost the overall detection efficiency throughout the Rock Island Dam right adult fish ladder. He recalled there was an unresolvable noise issue; however, maintenance on the existing array and installation of a new array will return the ladder to high detection efficiency. He said the new antenna is located between the powerhouse and auxiliary water system building in fairly close proximity to the existing antenna. He said there is a section of ladder with two overflow weirs and two orifices, each equipped with four arrays. He said early testing indicates the noise issues have been alleviated. He said Biomark is now waiting on fiber and an addition power conduit to finish the work and the anticipated water up date is March 1, 2019. *(Note:*

[1]AP = Ammocoete (Pacific); AB = Ammocoete (Brook); AS = Ammocoete (Unknown); and MP = Macropthalmia (Pacific)

Keller provided an email following the meeting on February 26, 2019, clarifying that all necessary work associated with the new PIT-tag array was completed as of February 25, 2019, and the right adult fish ladder was returned to service on February 25, 2019 at 10:00 a.m.)

Keller said the middle adult fish ladder was taken offline for annual winter maintenance on January 28, 2019. He said a fish rescue was performed and three juvenile rainbow/steelhead, adipose-present and between 4 to 6 inches, were rescued. He said the main inspection in the middle ladder will occur in the lower section. He recalled the installation of new butterfly valves 2 years ago, and when crews inspected the gear boxes the first one was full of water. He said the valves are still under warranty and were removed and sent to Texas for repair. He said the valves should be returned to Rock Island Dam for installation in time for the ladder to be returned to service by March 15, 2019. Keller said he had asked the mechanical foreman if there is any way to operate the ladder for the 2019 season without repairing the valves during this winter outage, and address this as the first issue during the 2019/2020 winter outage. Keller said the foreman did not have confidence in operating the ladder in this condition in 2019, which is the reasoning behind making the valve repairs and extending the expected return-to-service date of March 1 to March 15, 2019. Keller said as far as fish passage, the middle ladder is used the least compared to the right and left ladders, with the bulk of fish passage through the right ladder.

D. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said Rock Island Dam mechanics completed the disassembly of Turbine Unit B4 and are now working with Andritz Hydro to inspect the condition on the unit. Keller said the return-to-service date for Turbine Unit B4 is still July 2019.

E. Rocky Reach Dam Turbine Unit C1 Update (Lance Keller)

Lance Keller said disassembly of Turbine Unit C1 is continuing and mechanics are preparing to remove the rotor. Keller said the return-to-service date for Turbine Unit C1 is still August 2019.

F. Tumwater Dam Update (Lance Keller)

Lance Keller said in early February 2019, the contractor completed the exploratory drilling and learned two things: 1) the bottom layer of concrete below the fishway is not as thick as depicted on the design drawings and pin piles will not be effective; and 2) the extent of erosion was much less than first speculated. Keller said therefore, engineers do not think repairs are needed at this time. He said Chelan PUD is amending the Tumwater Dam Operations Plan to include further evaluation of these conditions during low water events.

G. 2019 Rock Island and Rocky Reach HCP Action Plan (Lance Keller)

Lance Keller said a draft 2019 Rock Island and Rocky Reach HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 12, 2019. Keller said this plan is available for a 30-day review with edits and comments due to Keller by Thursday, March 14, 2019. He said Chelan PUD will request approval of the plan during the HCP Coordinating Committees meeting on March 26, 2019. Keller said there were no significant changes to the HCP Coordinating Committees section; rather, only updates to dates. He asked that the Rock Island and Rocky Reach HCP Coordinating Committees contact him with questions.

H. 2019 Rock Island Bypass Monitoring Plan and 2019 RRJFBS Operations Plan (Lance Keller)

Lance Keller said a draft 2019 Rock Island Bypass Monitoring Plan and draft 2019 RRJFBS Operations Plan were distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, and are available for a 32-day review with edits and comments due to Keller by Monday, March 18, 2019. Keller said Chelan PUD will request approval of these plans during the HCP Coordinating Committees meeting on March 26, 2019.

Keller said changes to note in the 2019 Rock Island Bypass Monitoring Plan, include: 1) additional tagging of 3,000 wild and hatchery steelhead above and beyond the amount outlined for FPC SMP, which will be part of a Grant PUD avian predation study; and 2) continue fresh fish collection for GBT monitoring to the best of Chelan PUD's ability and as the run allows.

Keller said a change to note in the 2019 RRJFBS Operations Plan includes the integration of the altered operations to provide additional attraction water at the RRJFBS Surface Collector (SC)[2] directly into the plan. He clarified these operations will not be appended to the plan as was done in 2018; rather, the operations are now integrated into the 2019 plan.

I. 2019 Rock Island and Rocky Reach Fish Spill Plan (Lance Keller)

Lance Keller said a draft 2019 Rock Island and Rocky Reach Fish Spill Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, which is available for a 32-day review with edits and comments due to Keller by Monday, March 18, 2019. Keller said Chelan PUD will request approval of the plan during the HCP Coordinating Committees meeting on March 26, 2019. He said the plan is similar to past plans, including a note about converting selected notch gates to full gate capacity to provide Rock Island Dam with more immediate spillway capacity during heavy spring river flow events.

---

[2] Rocky Reach Dam bypass operations in 2019 will include: 1) using three additional RRJFBS SC pumps to increase attraction flow from 6,000 to 6,660 cfs into the RRJFBS SC entrances (3,330 cfs on each side); and 2) increasing Turbine Unit C2 flow from its normal soft-limit set-point of 12,200 cfs (12.2 kcfs) to a soft-limit flow of 15.2 kcfs.

V. HCP Administration

A. HCP Tributary Committees U.S. Fish and Wildlife Service Voting Member (John Ferguson)

John Ferguson said a letter requesting that USFWS be a voting member on the HCP Tributary Committees was received from Jim Craig on January 24, 2019.

B. 2018 HCP Annual Reports (John Ferguson)

John Ferguson reminded the HCP Coordinating Committees of upcoming review timelines for the 2018 HCP Annual Reports, as follows:

- 2018 Wells HCP Annual Report comments are due Wednesday, March 6, 2019
- 2018 Rock Island and Rocky Reach HCP Annual Reports comments are due Monday, March 18, 2019

The 2018 Wells HCP Annual Report was approved by the Wells HCP Coordinating Committee on March 22, 2019, after no disapprovals were received prior to the 37-day review period deadline and edits and comments received on the report were addressed and approved by the Colville Confederated Tribes. The final report was distributed to the HCP Coordinating Committees by Kristi Geris on March 25, 2019.

The 2018 Rock Island and Rocky Reach HCP Annual Reports were approved by the Rock Island and Rocky Reach HCP Coordinating Committees after no disapprovals were received prior to the 30-day review period deadline on March 18, 2019.

C. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on March 26, 2019, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The April 23 and May 28, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: April 23, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the March 26, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, March 26, 2019, from 10:00 to 11:30 a.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on passive integrated transponder (PIT)-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item I-C).
- Lance Keller will notify Jim Craig of what he determined about operating the weir box within the intake of Turbine Unit C1 to facilitate river flow through this area of the Intake Screen System with Turbine Unit C1 out of service during the 2019 bypass season (Item I-C).
- Lance Keller will inquire internally about the reasoning behind taking downstream-migrating Pacific lamprey at the Rocky Reach Juvenile Fish Bypass System (RRJFBS) and releasing these fish at an upstream location (Item I-C).
- Chelan PUD will provide a final timeline for repairing Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 hub seals to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-E).
- Tom Kahler will distribute recent reports by the Columbia River Inter-Tribal Fish Commission (CRITFC) that summarize findings from their sockeye salmon monitoring efforts (Item IV-A).
- The HCP Coordinating Committees meeting on April 23, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item V-C).

Decision Summary

- Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the 2019 Rock Island and Rocky Reach HCP Action Plan (Item III-A). *(Note: Jim Craig provided U.S. Fish and Wildlife Service [USFWS] approval of the plan via email on March 18, 2019, and Kirk Truscott provided Colville Confederated Tribes [CCT] approval of the plan via a phone call to Kristi Geris on March 25, 2019.)*
- Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the 2019 Rock Island and Rocky Reach Fish Spill Plan, as revised (Item III-B). *(Note: Jim Craig provided USFWS approval of the plan via email on March 18, 2019, and Kirk Truscott provided CCT approval of the plan via a phone call to Kristi Geris on March 25, 2019.)*
- Rock Island HCP Coordinating Committee representatives present approved the 2019 Rock Island Bypass Monitoring Plan, as revised (Item III-C). *(Note: Jim Craig provided USFWS approval of the plan via email on March 18, 2019, and Kirk Truscott provided CCT approval of the plan via a phone call to Kristi Geris on March 25, 2019.)*
- Rocky Reach HCP Coordinating Committee representatives present approved the 2019 RRJFBS Operations Plan, as revised (Item III-D). *(Note: Jim Craig provided USFWS approval of the plan via email on March 18, 2019, and Kirk Truscott provided CCT approval of the plan via a phone call to Kristi Geris on March 25, 2019.)*
- Wells HCP Coordinating Committee representatives present approved the 2019 Broodstock Collection Protocols (Item IV-B). *(Note: Kirk Truscott provided CCT approval of the protocols via a phone call to Kristi Geris on March 25, 2019.)*

Agreements

- HCP Coordinating Committees representatives present agreed to add Emi Kondo (National Marine Fisheries Service [NMFS]) to select HCP Hatchery Committees email distribution lists (Item V-B).

Review Items

- CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019 (Item IV-A).
- A draft 2017 Douglas PUD Pikeminnow Removal Annual Report was distributed to the HCP Coordinating Committees by Kristi Geris on January 29, 2019, which is available for a 60-day review with edits and comments due to Tom Kahler by Thursday, March 28, 2019.

Finalized Documents

- The Wells Project Survival Verification Study – Final 2020 Study Plan, which was approved by the Wells HCP Coordinating Committee on January 22, 2019, was distributed to the HCP Coordinating Committee by Kristi Geris on March 28, 2019.
- The Final 2018 Post-Season Bypass Report and Passage-Dates Analysis, which was approved by the Wells HCP Coordinating Committee on February 26, 2019, was distributed to the HCP Coordinating Committee by Kristi Geris on March 28, 2019.
- The Final 2019 Broodstock Collection Protocols were distributed to the HCP Coordinating Committee by Kristi Geris on March 29, 2019 (Item IV-B).
- The final 2018 Rock Island and Rocky Reach HCP Annual Reports were distributed to the HCP Coordinating Committees by Kristi Geris on April 8, 2019 (Item V-A).

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Scott Carlon added under HCP Administration a request to add Emi Kondo to select HCP Hatchery Committees email lists
- Tom Kahler added a Wells Dam bypass operations update

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft February 26, 2019 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. Geris said a minor edit was received from the Yakama Nation (YN) after the revised minutes were distributed. She said under Chelan PUD's 2018 Rock Island Smolt and Gas Bubble Trauma Evaluation Report topic, Keely Murdoch clarified that her comment about past sampling efforts at Rock Island Dam and observed gas bubble trauma expression was unrelated to efforts conducted by the YN, and she asked to omit this comment and leave the statement as her agreeing with Lance Keller's comments. Geris said she also updated the Review Items and Finalized Documents, as additional items were distributed. She also updated the Decision Summary to include approval of the Wells, Rock Island, and Rocky Reach HCP Annual Reports. HCP Coordinating Committees members present approved the February 26, 2019 meeting minutes, as revised. *(Note: Jim Craig provided USFWS approval of the February 26, 2019 meeting minutes via email on March 19, 2019, and Kirk Truscott provided CCT approval of the minutes via a phone call to Geris on March 25, 2019.)*

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on February 26, 2019, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on February 26, 2019):*

- *Lance Keller will review subyearling Chinook salmon sampled at the RRJSF during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on PIT-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in DART (Item I-C).*
  This action item will be carried forward.
- *Chelan PUD will provide a final timeline for repairing Rocky Reach Dam Turbine Unit C1 hub seals to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).*
  This action item will be discussed during today's meeting and will also be carried forward.
- *Tom Kahler will revise the draft 2018 Wells HCP Action Plan, as discussed, and will provide a final plan to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-A).*
  Kahler provided the final plan to Geris following the meeting on February 26, 2019, which Geris distributed to the HCP Coordinating Committees that same day.
- *Lance Keller will determine whether the weir box within the intake of Turbine Unit C1 was fixed to facilitate river flow through this area of the Intake Screen System with Turbine Unit C1 out of service during the 2019 bypass season (Item IV-A).*
  Keller said this fix was not completed because in order to troubleshoot the issue, the vertical barrier screen needs to be operational, which cannot occur while Turbine Unit C1 is out of commission. He said, however, a flushing valve will provide about 10 cubic feet per second (cfs) through the area to prevent fish from exiting the Turbine Unit C2 weir box and entering the Turbine Unit C1 weir box. Keller recalled this action item was to address a question Jim Craig asked about the 2019 RRJFBS Report, and Keller said he will communicate this response to Craig to close out the action item.
- *Lance Keller will inquire internally about the reasoning behind taking downstream-migrating Pacific Lamprey at the RRJFBS and releasing these fish at an upstream location (Item IV-A).*
  This action item will be carried forward.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on March 20, 2019 (*note: joint HCP Hatchery Committees/Priest Rapids Coordinating Committee [PRCC] Hatchery Subcommittee* *items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Broodstock Collection Protocols (joint)*: The HCP Hatchery Committees and PRCC Hatchery Subcommittee reviewed, edited, and approved the 2019 Broodstock Collection Protocols. The protocols were sent to the Wells HCP Coordinating Committee for review and approval. Once approved, the protocols will be submitted to NMFS.
- *Spring Chinook Salmon Carcass Recovery Bias (joint)*: The Washington Department of Fish and Wildlife (WDFW) provided a presentation titled, "Spring Chinook Carcass Recovery Bias in the Upper Wenatchee Basin." WDFW discussed how carcass bias was assessed, the factors affecting bias, and development of a model that can be used to adjust spawning escapements based on factors affecting bias. In general, bias is affected by stream flows, stream type, channel type, and fish size (age) and sex. Hillman said before, it was assumed that hatchery fish had a higher pre-spawn mortality rate; however, once escapements were adjusted for bias, WDFW found little difference in pre-spawn mortality between hatchery and natural-origin adults.
- *NMFS Consultation (joint)*: The Draft Environmental Assessment for Upper Columbia River Steelhead and Summer/Fall Chinook Salmon Programs is undergoing internal review and will soon be available for public review. Permits for the unlisted Chinook salmon programs are under review by General Council.
- *Bacterial Kidney Disease Testing (Wells)*: Douglas PUD has been sending virology samples (consisting of ovarian fluid, kidney, and spleen samples) to Washington Animal Disease Diagnostic Laboratory (WADDL) for processing and kidney samples to WDFW for traditional bacterial kidney disease ELISA (enzyme-linked immunosorbent assay) testing. Douglas PUD reported that WADDL has recently revised their protocols and can now report Optical Density values for bacterial kidney disease. Douglas PUD will determine if there is a cost difference between laboratories. The intent is to send all samples to WADDL for analysis.
- *Marking of 2018 Brood Chiwawa Spring Chinook Salmon (Rock Island/Rocky Reach)*: The Chiwawa spring Chinook salmon conservation program consists of juveniles from natural-origin spawners and hatchery-origin spawners. The question the Rock Island HCP Hatchery Committee is considering is should all fish within the program be marked the same or should fish within the program be marked differentially based on the origin of their parents? Unfortunately, the Spring Chinook Salmon Management Plan, Biological Opinions, Hatchery and Genetic Management Plans, and Permits are not clear and tend to conflict with each other on how the fish should be marked. The Rock Island HCP Hatchery Committee is working to resolve this issue.
- *Joint Meetings of the HCP Hatchery Committees and PRCC Hatchery Subcommittee*: The HCP Hatchery Committees and PRCC Hatchery Subcommittee are currently reviewing and updating their meeting protocols and distribution lists.

- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on April 17, 2019.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on March 14, 2019:

- *Upper Kahler Stream and Floodplain Enhancement Project*: In December 2018, the HCP Tributary Committees received a General Salmon Habitat Program proposal from the YN titled, "Upper Kahler Stream and Floodplain Enhancement Project." The purpose of the project is to reduce the risk of an avulsion near river mile 8.6 on Nason Creek by constructing a large, buried, log jam at the upstream inlet of the developing avulsion channel and filling the avulsion channel with large substrate. The project will also construct three additional buried bank jams and enhance fish habitat at the downstream end of the avulsion channel. The total cost of the project was $482,500. The sponsor requested $231,500 from HCP Plan Species Account Funds. In December 2018, the HCP Tributary Committees elected to not fund this project as currently designed but invited the YN to provide a presentation to the HCP Tributary Committees to explain the design of the project. In January 2019, the YN and their consultant provided a presentation describing the design of the proposed project. The HCP Tributary Committees struggled with the proposed filling of the avulsion channel with large sediments and recommended instead adding wood and a few boulders in the avulsion channel. These structures should help trap smaller sediments and fill the channel naturally. The YN provided a written response to the HCP Tributary Committees concerns and identified four alternatives, one of which was the original proposed action. After discussing the alternatives with the YN and their engineer, the Rock Island HCP Tributary Committee agreed to fund the four large wood structures within Nason Creek; however, elected to not fund any actions that would fill the avulsion channel and asked the YN to provide a cost estimate for constructing the four wood structures within Nason Creek. Hillman said once the Rock Island HCP Tributary Committee receives a budget and approves it, the YN can start construction. John Ferguson asked if the proposal is to rely on wood structures to trap sediment in the avulsion channel? Hillman said no, all wood structures will be placed in Nason Creek for bank stabilization, structure, and fish habitat; and the HCP Tributary Committees elected to not fund filling the avulsion channel. Hillman said the river will eventually migrate through the avulsion channel and the intent of this project is to prevent this from happening soon. He said the landowner reached out to the YN for help on this.
- *Stormy Project Area "A" Stream and Floodplain Enhancement Project*: In December 2018, the HCP Tributary Committees received a General Salmon Habitat Program proposal from the YN titled, "Stormy Project Area 'A' Stream and Floodplain Enhancement Project." The purpose of the project is to maintain salmon and steelhead spawning habitat within the middle Entiat River, improve mainstem juvenile rearing and adult holding habitat, and improve off-channel

juvenile rearing habitat. The total cost of the project was $1,652,218.15. The sponsor requested $1,140,968.15 from HCP Plan Species Account Funds. In December 2018, the HCP Tributary Committees elected to not fund this project as currently designed but invited the YN to provide a presentation to the HCP Tributary Committees to explain the design of the project. In January 2019, the YN and their consultant provided a presentation on the design of the Stormy Area A Project. Following the presentation and discussions with all members of the HCP Tributary Committees, the HCP Tributary Committees agreed to support the excavation of the perennial side channel on river right and the side channel on river left, including installing apex log jams used to control flows into the side channels. The HCP Tributary Committees asked the YN for a revised budget for the construction of the perennial side channels and apex jams. In February 2019, the YN submitted a revised proposal and cost estimate. The total cost of the project was reduced to $1,564,211.15 and the YN requested $823,161.15 from HCP Plan Species Account Funds. The Rocky Reach HCP Tributary Committee approved $823,161.15 for the project.

- *East Fork Mission Creek Floodplain Restoration Project*: The HCP Tributary Committees received a Small Project proposal from Chelan County Natural Resource Department (CCNRD) titled, "East Fork Mission Creek Floodplain Restoration Project." The purpose of this project is to develop permit-ready designs that will result in improved base flows in the Mission Creek watershed by reconnecting floodplain in a severely incised system and improve habitat for steelhead. CCNRD intends to accomplish this by removing an eroding road prism located within the floodplain, adding in-stream wood, and addressing potential passage barriers. The project is located along a 2.8-mile stretch of East Fork Mission Creek in the upper Mission Creek watershed. The total cost of the design project is $96,169. The sponsor requested $74,669 from HCP Plan Species Account Funds. The HCP Tributary Committees were unable to make a funding decision without more information on the status of the road. It is unclear if the road is permanently closed and formally abandoned. The HCP Tributary Committees have asked CCNRD to provide clarification on the closure of the road. Once this is received, the HCP Tributary Committees will make a funding decision.
- *2019 Eightmile Creek Fisheries Assessment Project*: The HCP Tributary Committees received a Small Project proposal from WDFW titled, "2019 Eightmile Creek Fisheries Assessment Project." The purpose of this project is to assess the status of fish within Eightmile Creek, a tributary to the Chewuch River in the Methow River Basin. These data will be used to determine a strategy for removing brook trout and restoring native salmonids to 21 kilometers of stream. Currently, a fish passage barrier near the mouth of Eightmile Creek precludes steelhead (and bull trout) from migrating into the stream. Because the YN are looking to remove the barrier, managers want information on species composition, fish abundance, stream flows, and temperatures within Eightmile Creek. Tissue samples from bull trout and

O. mykiss will also be collected within Eightmile Creek to determine genetic composition. The total cost of the project is $67,200. The sponsor requested the full amount from HCP Plan Species Account Funds. The HCP Tributary Committees were unable to make a funding decision and asked the sponsor to: 1) include a management plan that clearly identifies decision rules for determining which strategy would be selected for removing brook trout (i.e., what results are needed to determine whether to use electrofishing, piscicides, or other removal techniques); and 2) consider using electrofishing rather than snorkeling to conduct the assessments. Complete census surveys with electrofishing gear can be used to provide data on species richness and abundance and can be used to remove brook trout during the surveys. Hillman said the HCP Tributary Committees sent a letter to WDFW asking WDFW to address these issues, and once resolved, the HCP Tributary Committees can then make a funding decision.

- *Presentation by CCNRD on the Monitor Side Channel Design Project*: CCNRD and their consultants provided an update on the Monitor Side Channel Restoration Design Project, which the Rock Island HCP Tributary Committee funded in 2018. CCNRD described the goals and objectives of the project and identified design challenges and constraints. They also provided results from their hydraulic modeling work and presented conceptual designs that included boulder clusters, bank engineered log jams, weir logs, and willow trenches. Members provided feedback on the proposed conceptual designs. CCNRD and their consultants will continue working on the designs and will provide additional updates to the HCP Tributary Committees in the near future.
- *Wells HCP Tributary Committee Action Plan*: On January 17, 2019, Douglas PUD provided the HCP Tributary Committees with the Draft 2019 Wells HCP Action Plan for a 30-day review. Wells HCP Tributary Committee representatives reviewed the tributary section of the action plan and provided minor edits, which were incorporated into the plan. No other edits or comments were provided.
- *Rock Island and Rocky Reach HCP Tributary Committees Action Plans*: On February 11, 2019, Chelan PUD provided the HCP Tributary Committees with the Draft 2019 Rock Island and Rocky Reach HCP Action Plan for a 30-day review. Rock Island and Rocky Reach HCP Tributary Committees representatives reviewed the tributary section of the action plan and had no comments or edits.
- *Plan Species Account Deposits*: At the end of January 2019, the PUDs deposited funds into each of the Plan Species Accounts. Chelan PUD deposited $784,331.00 into the Rock Island Plan Species Account and $371,474.00 into the Rocky Reach Account. Douglas PUD deposited $284,793.79 into the Wells Account. As of March 2019, the unallocated balances within each account are $6,910,306.00 in the Rock Island Account, $3,215,267.00 in the Rocky Reach Account, and $1,813,698.00 in the Wells Account. Thus, among the three accounts, there is

about $11,939,271 available. Ferguson asked if the unallocated balance includes the decisions made in March 2019? Hillman said it does not, but accounting for decisions made during the meeting on March 14, 2019, the combined balance would decrease by about $1,000,000.

- *Review of a Draft Statement of Agreement*: On February 25, 2019, the YN submitted a draft Statement of Agreement (SOA) to the HCP Tributary Committees for review. The purpose of the draft SOA is to provide a basis for decision-making in the HCP Tributary Committees. The YN asked the HCP Tributary Committees to review and, if necessary, edit the draft SOA. The YN would like the HCP Tributary Committees to vote on the SOA during the HCP Tributary Committees meeting on April 11, 2019. There was a lot of discussion on the draft SOA including what precipitated the need for an SOA, why an SOA is necessary, and what will be accomplished by approving the SOA. Most members did not see a need for an SOA, thought the language was too strong, and took away each member's discretionary rights when reviewing and voting on project proposals. The CCT noted they cannot support any SOA that will take away their right to prevent the YN from owning land in the Methow River Basin. It was also pointed out that editing the draft SOA to preserve the discretionary voting rights of signatory parties would result in a very complicated document that would no longer fulfill the intent of the YN preparing the SOA. Most members thought it would be more appropriate to update Section 5 in the HCP Tributary Committees' Policies and Procedures for Funding Projects document. They thought the evaluation criteria currently being reviewed by the HCP Tributary Committees could be inserted into the Policies and Procedures document, and those can be reviewed and updated annually or more frequently if necessary. The HCP Tributary Committees believe this would eliminate the need for an SOA. That said, the YN asked members to review and edit the draft SOA and be prepared to discuss it and vote on it during the HCP Tributary Committees meeting on April 11, 2019. Hillman said no edits or comments have been received on the draft SOA to date. Ferguson asked each HCP Coordinating Committees representative if they had any questions or wanted to provide any additional comments at this time. Keely Murdoch reiterated that the YN will likely request a vote on the draft SOA during the HCP Tributary Committees meeting on April 11, 2019, but the YN are still discussing the SOA and reviewing their options. No other comments were expressed.
- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on April 11, 2019.

III. Chelan PUD

A. DECISION: 2019 Rock Island and Rocky Reach HCP Action Plan (Lance Keller)

Lance Keller said a draft 2019 Rock Island and Rocky Reach HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 12, 2019, and was available for a 30-day review with edits and comments due to Keller by Thursday, March 14, 2019. Keller said the tributary and hatchery sections have already been approved by the respective HCP Committees, and there are no outstanding edits or comments to be discussed.

Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the 2019 Rock Island and Rocky Reach HCP Action Plan. *(Note: Jim Craig provided USFWS approval of the plan via email on March 18, 2019, and Kirk Truscott provided CCT approval of the plan via a phone call to Geris on March 25, 2019.)*

B. DECISION: 2019 Rock Island and Rocky Reach Fish Spill Plan (Lance Keller)

Lance Keller said a draft 2019 Rock Island and Rocky Reach Fish Spill Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, and was available for a 32-day review with edits and comments due to Keller by Monday, March 18, 2019. Keller said questions were received from USFWS on March 6, 2019, which Keller responded to on March 15, 2019. Keller summarized USFWS questions, as follows:

Question 1: How was “shaped spill” derived for Rock Island and Rocky Reach dams?

Keller explained that spill shaping at both Rock Island and Rocky Reach dams was developed and informed from hydroacoustic data.

Question 2: For Rocky Reach Dam, why does the “spill shape %” not add up to 100?

Keller explained that spill shaping is a continuous event where the first hour of spill is a continuation of the last 13 hours of the previous day. He said Jim Craig expected the sum of the block releases to equal 100, which would be true if the values were representing total flow passing the project; however, this is not the case. Keller said it is just a coincidence that summing the block releases at Rock Island Dam equals 98.

Keller said his responses seemed to have adequately addressed Craig’s questions because Craig provided USFWS approval of the plan via email on March 18, 2019.

Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the 2019 Rock Island and Rocky Reach Fish Spill Plan, as revised. *(Note: Craig provided USFWS approval of the plan via email on March 18, 2019, and Kirk Truscott provided CCT approval of the plan via a phone call to Kristi Geris on March 25, 2019.)*

C. DECISION: 2019 Rock Island Bypass Monitoring Plan (Lance Keller)

Lance Keller said a draft 2019 Rock Island Bypass Monitoring Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019, and was available for a 32-day review with edits and comments due to Keller by Monday, March 18, 2019. Keller said editorial comments were received from USFWS on March 11, 2019, including wordsmithing to improve the flow of information and the addition of page numbers.

Rock Island HCP Coordinating Committee representatives present approved the 2019 Rock Island Bypass Monitoring Plan, as revised. *(Note: Jim Craig provided USFWS approval of the plan via email on March 18, 2019, and Kirk Truscott provided CCT approval of the plan via a phone call to Kristi Geris on March 25, 2019.)*

D. DECISION: 2019 Rocky Reach Juvenile Fish Bypass System Operations Plan (Lance Keller)

Lance Keller said a draft 2019 RRJFBS Operations Plan was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2019 and was available for a 32-day review with edits and comments due to Keller by Monday, March 18, 2019.

Rocky Reach HCP Coordinating Committee representatives present approved the 2019 RRJFBS Operations Plan, as revised. *(Note: Jim Craig provided USFWS approval of the plan via email on March 18, 2019, and Kirk Truscott provided CCT approval of the plan via a phone call to Kristi Geris on March 25, 2019.)*

E. Rocky Reach Dam Turbine Unit C1 Update (Lance Keller)

Lance Keller said the rotor has been removed from Turbine Unit C1 and mechanics are continuing disassembly of the unit to reach the trunnion bushings.

Keller said mechanics have now also detected a trunnion seal leak in Turbine Unit C3. He said on October 31, 2018, Turbine Unit C3 was taken offline for routine overhaul work and mechanics discovered about 5 gallons of water inside the hub, but no recordable oil loss was documented. Keller said considering the issues experienced with Turbine Unit C1, mechanics decided to run and test the unit, which the unit passed, and the unit was returned to service on December 31, 2018. Keller said mechanics continued monitoring the tailrace for the presence of oil, and on February 19, 2019, the unit was taken offline to check the level of oil in the unit. He said this time, mechanics discovered more than 5 gallons of water inside the hub, and crews are still working internally to determine how much oil has been lost. He said last week, the engineered seals designed for Turbine Unit C1 were installed in Turbine Unit C3, the unit was pressurized, and the seals did not work; therefore, Turbine Unit C3 is out-of-service. He said mechanics are now moving through the same evaluation process as was done for Turbine Unit C1, including considering hydraulically locking the blades into place. He said a person working for Alstom on Turbine Unit C9 suggested using a compound that is injected into the hub to improve the seal and allow the blades to operate in a Kaplan configuration. He said Rocky Reach Dam mechanics are currently considering both of these options as well as others. He said two key things to note, include: 1) based on current snowpack and water forecasts, Chelan PUD is not expecting an impact to total dissolved gas due to the decreased powerhouse capacity; and 2) work on Turbine Unit C3 will not impact the return-to-service date for Turbine Unit C1, which is still August 2019.

Keely Murdoch asked if having both Turbine Unit C1 and Turbine Unit C3 out-of-service will affect attraction flow? Keller said there are no available survival study data to review that specifically address this; however, he discussed this with Steve Hemstrom and Alene Underwood, and they do not anticipate an impact. Keller said additionally, Turbine Unit C1 and Turbine Unit C3 are located in a cul-de-sac which provides six passage routes (three turbine routes, two bypass screen routes, and one route via the surface collector structure). He said Turbine Unit C2 is currently the closest operating turbine passage route to the surface collector structure, and with both Turbine Unit C1 and Turbine Unit C3 offline, it seems once fish reach the cul-de-sac area the odds of fish passing via the collection system is increased with Turbine Unit C3 out-of-service.

Keller said Chelan PUD did ask Dr. John Skalski (Columbia Basin Research) to review juvenile survival data in terms of meeting survival standards with Turbine Unit C1 out-of-service. Keller said with Turbine Unit C1 offline, this means half of the available passage routes via diversion screens are not available. He said Skalski used spring Chinook salmon data from 2010 and 2011 to determine route-specific survival and passage proportions. Keller said Skalski took an estimated reduction in bypass collection efficiency (i.e., reduced 50% use in diversion screens) and applied this to the powerhouse passage route to determine the overall project survival and combined adult and juvenile survival. Keller said all three scenarios involved a 50% reduction in bypass screen efficiency, and then additional reductions of 2.5%, 5%, and 7.5% in the proportion of overall fish bypassed via the surface collector passage route were applied. He said day and night passage proportions and survivals were applied to dam survival and then project survival, and those were then multiplied to calculate the combined adult and juvenile survival. He said Skalski also found under all scenarios the project will continue to meet combined 91% juvenile and adult survival standard on a year-to-year basis. Keller said in summary, Chelan PUD does not believe there will be an impact from Turbine Unit C3 being out-of-service. He said if there is a slight reduction in collection efficiency, the project will still meet the survival standards under all three scenarios Skalski modeled.

Scott Carlon asked about the modified bypass operations to increase flow through the screens. Keller explained that these operations will include: 1) using three additional RRJFBS surface collector pumps to increase attraction flow from 6,000 to 6,660 cfs into the RRJFBS surface collector entrances (3,330 cfs on each side); and 2) increasing Turbine Unit C2 flow from its normal soft-limit set-point of 12,200 cfs (12.2 kcfs) to a soft-limit flow of 15.2 kcfs. Keller recalled these modified operations were initially developed in 2013 to accommodate repairs to the wedge carriers in Turbine Unit C1 and Turbine Unit C2. He said the operations were developed in consultation with Bryan Nordlund (NMFS, retired) and the Rocky Reach HCP Coordinating Committee to increase velocity through the area without creating concern for impingement.

Keller said a marked fish release was also conducted last week in the RRJFBS and intake screen system deployed in Turbine Unit C2 to verify no impingements under the modified bypass operations. He said there were issues with the Turbine Unit C2 release, and crews plan to retest this release at a later date.

Chad Jackson asked if the Turbine Unit C1 and Turbine Unit C3 repairs will impact planning for the 2021 survival study. Keller said as of now, Chelan PUD does not foresee these repairs impacting the study.

Murdoch asked if this issue with failing trunnion seals might be happening in the other turbine units. Keller said the larger units, Turbine Units C8 to C11, are all designed the same, and the smaller units, Turbine Units C1 to C7, are all designed the same. He said Rocky Reach Dam mechanics are monitoring trunnion bushing wear in the units and Rocky Reach Dam engineers are using the information from Turbine Unit C1 and Turbine Unit C3 to evaluate the other small units. Keller said the Rocky Reach Dam engineers are also looking to refine the data on the trunnion bushings and Chelan PUD is also looking into other seal contractors, as well.

Keller said he will add Turbine Unit C3 to the regular Turbine Unit C1 updates to the HCP Coordinating Committees.

F. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said as of last month, Rock Island Dam mechanics completed the disassembly of Turbine Unit B4 and they are now developing a plan to inspect the liner. Keller said this entails accessing the discharge ring and liner to analyze what repairs are needed. He explained that the liner is the interaction point where the tips of the turbine blades meet the rest of the turbine pit. He said the unit is equipped with its original discharge ring and liner, so mechanics are investigating what is needed to uphold the integrity of these components. Keller said the return-to-service date for Turbine Unit B4 is still July 2019.

John Ferguson asked what work is planned after Turbine Unit B4? Keller said the maintenance will continue moving towards the Douglas County side of the river starting with Turbine Unit B3. He recalled Turbine Unit B4 is the closest small unit to the spillway and the first small unit in the operating sequence of Powerhouse 1.

G. Rock Island Adult Fishway Maintenance Update (Lance Keller)

Lance Keller recalled when the attraction water system valves installed in the bottom of the middle fish ladder at Rock Island Dam were inspected, mechanics found water and scouring in the gear boxes. Keller said the mechanical foreman did not have confidence to operate the ladder for the 2019 season without first repairing the valves; therefore, the valves (still under warranty) were extracted and sent to Texas for repair. Keller said the valves were received and installed and the middle fish ladder was back online on March 15, 2019. He noted that March 15, 2019, is outside the regular maintenance window of December to February, but also noted that as far as fish passage, the middle ladder is used the least compared to the right and left ladders, with the bulk of fish passage occurring through the right ladder. Keller said all fish ladders at Rock Island Dam are now fully operational.

IV. Douglas PUD

A. CRITFC's Annual Request to Tag Sockeye Salmon at Wells Dam in 2019 (Tom Kahler)

Tom Kahler said CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019. Kahler said Kirk Truscott indicated the CCT are not yet ready to vote on this request (via a phone call to Geris on March 25, 2019), and Douglas PUD is okay with postponing the vote. Kahler said a vote will be needed no later than the HCP Coordinating Committees meeting on May 28, 2019.

Kahler said Jim Craig provided USFWS approval of this request via email on March 12, 2019. Kahler said Craig also suggested developing and distributing an annual post-tagging report containing data such as how many fish were tagged and problems encountered, if any, as well as a final summary report of findings when the study concludes. Kahler said the HCP Coordinating Committees made a similar request years ago, and in 2013, Jeff Fryer (CRITFC) provided an in-person presentation to the HCP Coordinating Committees about Fryer's work in general and working with the Okanagan Nation Alliance in British Columbia towards monitoring Canadian Okanagan River sockeye salmon. Kahler said Fryer publishes reports on this work and makes them publicly available. Kahler said he will distribute recent reports by CRITFC, which summarize findings from their sockeye salmon monitoring efforts.

B. DECISION: 2019 Broodstock Collection Protocols (Tom Kahler)

Tom Kahler said the draft 2019 Broodstock Collection Protocols were distributed to the HCP Coordinating Committees by Kristi Geris on March 23, 2019. Kahler recalled the Wells HCP stipulates that the Wells HCP Coordinating Committee will review the protocols, particularly regarding trapping effects on fish passage. Kahler said there were no changes in the proposed trapping under this year's protocols compared to last year's Wells HCP Coordinating Committee-approved protocols and he is unaware of any reasons not to approve the 2019 protocols. He said once approved, the protocols will be submitted to NMFS by April 15, 2019.

John Ferguson noted that Kahler and Keely Murdoch already provided Douglas PUD and the YN approval, respectively, via the HCP Hatchery Committees and PRCC Hatchery Subcommittee approvals on March 22, 2019. Ferguson said Kirk Truscott provided CCT approval of the protocols via a phone call to Geris on March 25, 2019.

Wells HCP Coordinating Committee representatives present approved the 2019 Broodstock Collection Protocols. The Final 2019 Broodstock Collection Protocols were distributed to the HCP Coordinating Committee by Geris on March 29, 2019.

C. Wells Dam Bypass Operations Update (Tom Kahler)

Tom Kahler said Wells Dam mechanical staff are in the process of installing the bypass barriers at Wells Dam. Kahler said all barriers are in place except for one in Bypass Bay 2. He further explained that the turbine intakes and spillway intakes are staggered, and the bypass barrier for one of the intake slots for Bypass Bay 2 is not yet installed, which is located above one of the turbine unit intakes for Turbine Unit 2. Kahler clarified this is not the same as the baffles with the PIT-tag antenna, which are installed all of the time. He said bypass operations begin on April 9, 2019.

V. HCP Administration

A. 2018 HCP Annual Reports (John Ferguson)

John Ferguson said the 2018 Wells HCP Annual Report was approved by the Wells HCP Coordinating Committee on March 22, 2019, after no disapprovals were received prior to the 37-day review period deadline and edits and comments received on the report were addressed and approved by the CCT. The final report was distributed to the HCP Coordinating Committees by Kristi Geris on March 25, 2019.

Ferguson said the 2018 Rock Island and Rocky Reach HCP Annual Reports were approved by the Rock Island and Rocky Reach HCP Coordinating Committees after no disapprovals were received prior to the 30-day review period deadline on March 18, 2019. Geris said the final reports will be distributed in early April 2019. *(Note: the final 2018 Rock Island and Rocky Reach HCP Annual Reports were distributed to the HCP Coordinating Committees by Geris on April 8, 2019.)*

B. HCP Hatchery Committees Email Distribution List – Emi Kondo (Scott Carlon and John Ferguson)

John Ferguson said a request was received from Brett Farman (NMFS HCP Hatchery Committees Representative) to replace Amilee Wilson (NMFS) with Emi Kondo on the final HCP Hatchery Committees agendas and meeting minutes email distribution lists. Keely Murdoch said Wilson formerly worked on permitting for the HCP Hatchery Committees, but now Kondo does this work.

HCP Coordinating Committees representatives present agreed to add Kondo to select HCP Hatchery Committees email distribution lists.

C. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on April 23, 2019, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The May 28 and June 25, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: May 28, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the April 23, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, April 23, 2019, from 10:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on passive integrated transponder (PIT)-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item I-C).
- Lance Keller will inquire internally about the reasoning behind taking downstream-migrating Pacific lamprey at the Rocky Reach Juvenile Fish Bypass System (RRJFBS) and releasing these fish at an upstream location (Item I-C).
- Tom Kahler will distribute recent reports by the Columbia River Inter-Tribal Fish Commission (CRITFC) that summarize findings from their sockeye salmon monitoring efforts (Item I-C). *(Note: Kahler provided a CRITFC report covering 2016 and 2017 tagging efforts to Kristi Geris on May 20, 2019, which Geris distributed to the HCP Coordinating Committees that same day; the 2018 report will be available in late summer 2019.)*
- Tracy Hillman will further discuss with the HCP Hatchery Committees and Priest Rapids Coordinating Committee (PRCC) Hatchery Subcommittee about combining the committees' email distribution lists and will report back to the HCP Coordinating Committees regarding the path forward (Item II-A). *(Note: Hillman provided updated HCP Hatchery Committees and PRCC Hatchery Subcommittee email distribution lists for HCP Coordinating Committees approval to Kristi Geris on May 20, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Kirk Truscott will contact Jeff Fryer (CRITFC) to obtain clarification on questions the Colville Confederated Tribes (CCT) have about CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 (Item III-A).

- Kirk Truscott will contact Lance Keller to further discuss options to increase attraction flow through the cul-de-sac area in the Rocky Reach Dam forebay (near Turbine Units C1, C2, and C3) while Turbine Units C1 and C3 are offline for maintenance (Item IV-A).
- Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item IV-A).
- Kristi Geris will coordinate with Denny Rohr (PRCC Facilitator) regarding moving the PRCC meeting on May 22, 2019 to May 29, 2019, to dovetail with the HCP Coordinating Committees meeting on May 28, 2019 (Item V-A). *(Note: Geris confirmed with Rohr via email on April 25, 2019, that the PRCC meeting on May 22, 2019 has been rescheduled to May 29, 2019.)*
- The HCP Coordinating Committees meeting on May 28, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item V-A).

Decision Summary

- There were no HCP Decision Items approved during today's meeting.

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019 (Item III-A).

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Lance Keller added: 1) Rock Island Dam 2019 Spring Spill; and 2) Subyearling Chinook Salmon Statement of Agreement (SOA)
- Ferguson added HCP Hatchery Committees and PRCC Hatchery Subcommittee Email Distribution Lists under the HCP Hatchery Committees Update

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft March 26, 2019 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. HCP Coordinating Committees members present approved the March 26, 2019 meeting minutes, as revised. The CCT and U.S. Fish and Wildlife Service (USFWS) abstained, because CCT and USFWS representatives were not present during the March 26, 2019 meeting.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on March 26, 2019, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on March 26, 2019):*

- *Lance Keller will review subyearling Chinook salmon sampled at the RRJSF during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on PIT-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in DART (Item I-C).*
  This action item will be carried forward.
- *Lance Keller will notify Jim Craig of what he determined about operating the weir box within the intake of Turbine Unit C1 to facilitate river flow through this area of the Intake Screen System with Turbine Unit C1 out of service during the 2019 bypass season (Item I-C).*
  Keller said he and Craig discussed this action item.
- *Lance Keller will inquire internally about the reasoning behind taking downstream-migrating Pacific lamprey at the RRJFBS and releasing these fish at an upstream location (Item I-C).*
  This action item will be carried forward.
- *Chelan PUD will provide a final timeline for repairing Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 hub seals to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-E).*
  This will be discussed during today's meeting.
- *Tom Kahler will distribute recent reports by CRITFC that summarize findings from their sockeye salmon monitoring efforts (Item IV-A).*
  Kahler said past reports up to 2015 are available for download from CRITFC's website; however, more current reports were not available. He said he will contact Jeff Fryer to ask about more recent reports. This action item will be carried forward.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on April 17, 2019 (*note: joint HCP Hatchery Committees/PRCC Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Marking of 2018 Brood Chiwawa/Nason Conservation Program Spring Chinook Salmon (joint)*: Recall the Chiwawa spring Chinook salmon conservation program consists of juveniles from natural-origin spawners (wild-by-wild [WxW]) and hatchery-origin spawners (hatchery-by-hatchery [HxH]). During the HCP Hatchery Committee meeting on March 11, 2019, the Rock Island HCP Hatchery Committee discussed whether all fish within the Conservation Program should be marked the same or differentially based on the origin of their parents. Following the meeting, the Joint Fisheries Parties convened and identified a possible marking strategy. The Joint Fisheries Parties proposed a second mark/tag for HxH fish within the conservation programs. Thus, HxH spring Chinook salmon within the Chiwawa Conservation Program will receive a coded wire tag (CWT) in the snout and a blank wire tag in the caudal area. WxW spring Chinook salmon in the Chiwawa Conservation Program will only receive a CWT in the snout. All conservation fish will retain the adipose (ad) fin. Only safety net program fish will be ad-clipped. Safety net program fish will also receive a CWT in the snout. Unlike the Chiwawa Conservation Program, both WxW and HxH Nason Creek conservation fish will receive a double tag; WxW spring Chinook salmon will receive a CWT in the snout and a blank wire tag in the dorsal area, and HxH spring Chinook salmon will also receive a CWT in the snout and a blank wire tag in the caudal area. Thus, all release groups and crosses will be uniquely marked. The Rock Island HCP Hatchery Committee approved the marking strategy provided Grant PUD approves the strategy for the Nason Creek programs.
- *Broodstock Collection Protocols Timeline (joint)*: The 2019 Broodstock Collection Protocols are now complete, and the HCP Hatchery Committees and PRCC Hatchery Subcommittee are now planning for the next protocols, including beginning the process of updating the protocols in September. This will allow the Committees time to identify major program changes that require extensive review and approval by the Committees (e.g., through an SOA) versus issues that can simply be addressed within the protocols document. In addition, the Committees will identify members who can help develop different sections of the Broodstock Collection Protocols. Historically, the protocols have been written by Washington Department of Fish and Wildlife, and this will allow all Committees members to contribute, including the PUDs.

Additionally, an earlier start on the protocols should reduce the time needed to review and discuss protocol changes in the new year.

- *National Marine Fisheries Service (NMFS) Consultation Update (joint)*: NMFS recently requested public comment on the Draft Environmental Assessment for Upper Columbia River Steelhead and Summer/Fall Chinook Salmon Programs and their associated Hatchery and Genetics Management Plans. Comments on these documents are due to NMFS on May 2, 2019. Permits for the unlisted Chinook salmon programs are under review by General Council. Kirk Truscott asked if NMFS provided an update on the release of the steelhead permits. Hillman said they did not, and he thinks the last update provided was that NMFS was unsure about the release timing of the permits.
- *Joint Meetings of the HCP Hatchery Committees and PRCC Hatchery Subcommittee (joint)*: The HCP Hatchery Committees are reviewing their email distribution lists. Hillman said logistically, it would be easiest to distribute a single email to both the HCP Hatchery Committees and PRCC Hatchery Subcommittee, as opposed to separate emails to each respective committee, which would also reduce duplicative emails to members on multiple lists. He said some people on the PRCC Hatchery Subcommittee email lists are not currently on the HCP lists and vice versa. He said he believes it is important to develop two lists; one list to receive all materials (draft and final) and one list for final materials only. He suggested the HCP Hatchery Committees develop these lists for HCP Coordinating Committees review, including justification for why non-Committees members are included on the lists. He suggested that Grant PUD representatives are to be included on the all materials list. John Ferguson said he liked the idea of the HCP Hatchery Committees vetting the lists carefully and bringing the lists to the HCP Coordinating Committees for review. Ferguson said since this is a question about adding Grant PUD staff to HCP lists and there are no Grant PUD members on the HCP Coordinating Committees, he suggested that Hillman as Chair of the HCP Hatchery Committees bring this request forward for review. Truscott said the CCT approves of this approach or would also accept a memorandum from the HCP Hatchery Committees as a whole. Hillman noted that the HCP Hatchery Committees have not yet heard back from Grant PUD about whether Grant PUD wants PRCC Hatchery Subcommittee products distributed to the HCP distribution lists; therefore, it is still unclear if merging the lists will actually happen. Hillman said he will further discuss combining the committees' email distribution lists with the HCP Hatchery Committees and PRCC Hatchery Subcommittee and will report back to the HCP Coordinating Committees regarding the path forward. *(Note: Hillman provided updated HCP Hatchery Committees and PRCC Hatchery Subcommittee email distribution lists for HCP Coordinating Committees approval to Kristi Geris on May 20, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*
- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on May 15, 2019.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on April 11, 2019:

- *Upper Kahler Stream and Floodplain Enhancement Project*: Recall this General Salmon Habitat Program proposal has been under discussion since 2018. The project is on Nason Creek. The Rock Island HCP Tributary Committee agreed to fund the four large wood structures associated with the project, which was submitted by the Yakama Nation (YN). During the HCP Tributary Committees meeting on March 14, 2019, the Rock Island HCP Tributary Committee indicated they would not fund any actions associated with filling the avulsion channel. The Rock Island HCP Tributary Committee asked the YN to provide a detailed budget for the construction of the four large wood structures within Nason Creek. On April 1, 2019, the YN provided a revised budget for the construction of the four wood structures within Nason Creek. After review, the Rock Island HCP Tributary Committee approved the budget for $149,000.
- *Evaluating Environmental Impacts of Tumwater Dam*: The HCP Tributary Committees received a General Salmon Habitat Program proposal from Cascade Columbia Fisheries Enhancement Group titled, "Evaluating Environmental Impacts of Tumwater Dam." The purpose of the project is to evaluate how Tumwater Dam affects water quality and habitat forming processes. Specifically, the project will: 1) quantify the difference between existing and historical habitat conditions within the vicinity of the dam and Lake Jolanda; 2) evaluate how water quality (e.g., temperature and dissolved oxygen) in Lake Jolanda may affect fish migration and behavior; 3) quantify and classify sediments stored behind Tumwater Dam; 4) test sediment behind Tumwater Dam for toxins or heavy metals; and 5) evaluate hydraulics and slope stability of Highway 2 and Lake Jolanda shorelines within a dam removal scenario. The total cost of the project is $279,600. The sponsor requested $139,800 from HCP Plan Species Account Funds. After careful review, the HCP Tributary Committees elected to not fund the assessment. Although the HCP Tributary Committees see value in better understanding entrance efficiency, thermal regimes, and sediments, the HCP Tributary Committees believe the cost of the proposed work is too expensive and noted that results from the work will not be compelling enough to lead to dam removal in the near future. Much of this work would need to be repeated in the future should dam removal ever be considered. Furthermore, the effects of Tumwater Dam on fish have not been identified as important data gaps by the Regional Technical Team, nor is Tumwater Canyon (middle Wenatchee) a priority area for restoration.
- *East Fork Mission Creek Floodplain Restoration*: In March 2019, the HCP Tributary Committees received a Small Project proposal from Chelan County Natural Resource Department (CCNRD) titled, "East Fork Mission Creek Floodplain Restoration Project." The purpose of this project is to develop permit-ready designs that will result in improved base flows in the Mission Creek watershed by reconnecting floodplain in a severely incised system and improve habitat for steelhead. CCNRD intends to accomplish this by removing an eroding road prism located

within the floodplain, adding in-stream wood, and addressing potential passage barriers. The project is located along a 2.8-mile stretch of East Fork Mission Creek in the upper Mission Creek watershed. The total cost of the design project is $96,169. CCNRD requested $74,669 from HCP Plan Species Account Funds. During the HCP Tributary Committees meeting on March 14, 2019, the HCP Tributary Committees were unable to make a funding decision because it was unknown whether the U.S. Forest Service (USFS) road is officially and permanently closed. On March 27, 2019, CCNRD informed the HCP Tributary Committees the road is not officially and permanently closed. Based on this information, the HCP Tributary Committees elected to not fund the project. The HCP Tributary Committees indicated they would reconsider the proposal if the road is officially and permanently closed, and an upland trail is constructed. Jim Craig asked if there is any desire by USFS to close this road. Hillman said his understanding is there is not because the road is used by recreational vehicles. He said, however, USFS is interested in building a new trail for recreational vehicle use upland of the existing road and proposed project area so USFS can remove the existing road. Craig asked if there is movement to build the trail. Hillman said yes, the project sponsor is currently seeking a cost share or separate funding to complete this work. He said once the new trail is built and the existing road is closed, the HCP Tributary Committees will reconsider funding this project.

- *Coordination with the U.S. Bureau of Reclamation on the Sugar Levee Project*: The U.S. Bureau of Reclamation (Reclamation) met with the HCP Tributary Committees to discuss a cooperative relationship between Reclamation and the HCP Tributary Committees on the Sugar Levee Project. The purpose of the project is to evaluate removal or breaching of the Sugar Levee, which is located near river mile 42.2 in the Middle Reach of the Methow River just upstream from the Town of Twisp. This project will reconnect side channels and more than 17 acres of floodplain habitat. This project was identified as a possible targeted project by the HCP Tributary Committees. Following the meeting with Reclamation, the HCP Tributary Committees agreed to work with Reclamation on developing the Sugar Levee Enhancement Project. Importantly, the relationship allows any party to exit the process at any time if the party sees the process going in the wrong direction. Ferguson asked what this partnership means? Hillman said this means HCP Tributary Committees members will be participating in meetings with Reclamation on behalf of the HCP Tributary Committees. He explained that Reclamation is identifying target project areas similar to what the HCP Tributary Committees are doing, and Sugar Levee is a common target between the two. He said Reclamation will take the lead on moving this project forward and at some point, Reclamation will not have the resources to move the project forward; therefore, Reclamation needs a funding partner. He said Reclamation distributed a request for proposals to design the project and develop alternatives for removing the levee, which is where the HCP Tributary Committees come in. He said Reclamation also has technical services in Colorado to complete the modeling work at no cost to the HCP Tributary Committees. He said the HCP Tributary Committees indicated interest in being involved in every step of the process and the Committees can provide funding to help move the project forward; however, if the HCP Tributary Committees believe the process is headed in the wrong direction the Committees have the option to opt out. He said Reclamation is doing most of the planning and modeling, while the HCP Tributary Committees would help with the design and provide funding.

- *Review of the YN Draft SOA*: On February 25, 2019, the YN submitted a draft SOA to the HCP Tributary Committees for review. The purpose of the draft SOA is to provide a basis for decision-making in the HCP Tributary Committees. The YN asked members to review the draft SOA, edit it as necessary, and vote on it during the HCP Tributary Committees meeting on April 11, 2019. Because no edits were offered prior to or during the meeting on April 11, 2019, Hillman asked each member to vote on the existing SOA and provide their reasons for their yes or no vote. All members except the YN voted no on the SOA. The primary reason given for members' lack of support for the SOA was because members found no need for an SOA, especially given the recent and ongoing development of evaluation criteria. Some noted the SOA is too restrictive and others suggested the SOA does not address the underlying issue between the YN and the CCT. The CCT voted no because the CCT cannot support an SOA that removes their right to prevent the YN from owning property in the Upper Columbia River Basin. The YN are currently evaluating whether they will dispute the decision by the HCP Tributary Committees. Ferguson asked Tom Kahler and Keely Murdoch if Douglas PUD or the YN, respectively, have updates to add. Kahler and Murdoch said they have nothing further to add.
- *Review of Section 5 of the Policies and Procedures Document*: During the HCP Tributary Committees meeting on March 14, 2019, the HCP Tributary Committees directed Hillman to add the evaluation criteria into Section 5 of the Policies and Procedures for Funding Projects document. Hillman added the criteria to Section 5 and the HCP Tributary Committees reviewed and edited the criteria. After discussion, the HCP Tributary Committees approved the revisions to Section 5 of the Policies and Procedures document.
- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on Wednesday, May 8, 2019 (rather than the typical second Thursday of the month) because the HCP Tributary Committees will be reviewing approximately 15 to 20 draft Salmon Recovery Funding Board and HCP Tributary Committees proposals. Hillman said the proposals will be evaluated as fundable or not fundable. He said for fundable proposals, the HCP Tributary Committees will ask sponsors to submit a final proposal to be evaluated in July 2019.

III. Douglas PUD

A. CRITFC's Annual Request to Tag Sockeye Salmon at Wells Dam in 2019 (Tom Kahler)

John Ferguson recalled CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019. Ferguson also recalled that Kirk Truscott requested additional time before voting to address a few questions he had about the request.

Truscott said he has not yet addressed these questions. He said he knows a decision is needed by May 2019 and he hopes to be ready to vote before this time. Tom Kahler asked if there is anything Douglas PUD can do to help address these questions. Truscott said no; rather, he needs to coordinate with Jeff Fryer to obtain clarification on a few details. Truscott said the request does not specify what will be used to anesthetize the fish. Keely Murdoch said she believes Aqui-S will be used similar to last year. Truscott said he also has a preference on tag location (i.e., what part of the fish will be tagged). He said a portion of the sockeye salmon run is already receiving tags at Bonneville Dam. He said the less these fish are handled the better. He said CRITFC's request also indicates that sampling will be coordinated with brood collection, and he wants to verify this means trapping will be conducted concurrent with the other collection efforts.

Truscott said he will contact Fryer to obtain clarification on questions the CCT have about CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019. Ferguson suggested that Truscott email the HCP Coordinating Committees with the responses to these questions once obtained and before the HCP Coordinating Committees meeting on May 28, 2019.

B. Wells Dam Bypass Operations Update (Tom Kahler)

Tom Kahler said an email about bypass operations at Wells Dam was distributed to the HCP Coordinating Committees by Kristi Geris on April 10, 2019.

Kahler said when bypass operations started at Wells Dam (on April 9, 2019 at 00:00 hours), Douglas PUD was in the process of recommissioning Turbine Unit 2, which had been offline for a unit overhaul; therefore, Spillway 2 remained offline. He said additionally, per the Wells Dam 2019 Bypass Operating Plan, a turbine cannot be operated without an adjacent bypass unit operating, which means while Spillway 2 is not in operation, Turbine Unit 1 also cannot be in operation. He said because the barriers for a bypass sit on top of the turbine intake bulkheads, recommissioning a turbine unit requires a labor-intensive process involving removing the bulkheads, installing the trash racks, and reinstalling the bypass barriers back on top of the trash racks. He said crews completed this process for Turbine Unit 2, the unit was reset to re-water, and commissioning of Spillway 2 was initiated; but then a contractor removed a pipe and underestimated the pressure of the water inside, which ultimately flooded Turbine Units 1, 2, and 3. Kahler said, therefore, commissioning of Turbine Unit 2 was halted, and Turbine Unit 1 remained offline. He said Spillway 2 finally resumed operation on April 22, 2019, and Turbine Unit 1 is now also online. He said Spillway 4 was taken offline today, April 23, 2019 (because the rebuild of Turbine Unit 3 began). He said Turbine Units 3 and 4 will remain offline until the trash racks and bulkheads are swapped in the intakes of Turbine Unit 3 and the bypass barriers are reinstalled. He said then Turbine Unit 4 and Spillway 4 will resume operation, and Turbine Unit 3 will remain offline until completion of the rebuild.

Kirk Truscott asked how long Spillway 2 was offline. Kahler said the spillway was on and off over one weekend. Truscott noted that Spillway 2 is the bay with the PIT-tag array where the HCP Coordinating Committees are hoping to collect data on emigration timing of early yearling spring Chinook salmon. Kahler said yes, this was unfortunately a lost data opportunity. Truscott asked why this rebuild and recommissioning of Turbine Unit 2 was not scheduled to be complete prior to the fish passage season. He said these types of setbacks do not sit well with him in that it seems fish are an afterthought in scheduling. Kahler said the schedule was to have Turbine Unit 2 operational by the end of 2018, but things went wrong on the contractors' side that resulted in unexpected delays. He said this was a complete overhaul, which typically requires an 18-month schedule. Truscott said this is unfortunate and asked if there is any way to prevent this from happening in the future. He asked if this is a 20-year contract to rebuild the entire system, and Kahler replied yes.

Kahler said another challenge is that the Wells Project Chief Engineer, Ken Pflueger, who was on staff for over 30 years retired last fall. Kahler said Pflueger was a contractor/consultant working on projects associated with Wells Dam before joining Douglas PUD and was an excellent nexus between Natural Resource staff, contractors, and dam operations. Kahler said Pflueger was an advocate for natural resources, was great at anticipating conflicts between contracts and operations, and understood compliance with the Federal Energy Regulatory Commission and total dissolved gas requirements. Kahler said since Pflueger retired, the importance of his role in the seamless consideration of fish in project operations has become apparent, and Natural Resource staff are working to establish necessary coordination with dam operations regarding operations with potential to affect compliance with agreements. He added that every turbine unit is taken offline at least once every 2 years for biannual maintenance, in addition to any units removed from service for overhauling. He said so long as Natural Resource staff are involved in these conversations, they can have influence, which has been done in the past. Truscott noted that it is a big deal to have all spillways online as required by the Wells HCP. Kahler said at least four of five spillways have been in operation during this bypass season, which is consistent with Section 4.3 of the Wells HCP. He said Spillway 2 where the PIT-tag antenna is located is the only spillway that was not in operation. Truscott said this is what is frustrating; that the HCP Coordinating Committees discussed and planned using this location to collect data on early emigrating yearling spring Chinook salmon and the data were missed. Kahler said some data were collected. He said fish can swim into this area in the forebay even though water is not flowing through the spillway or associated unit. He said he plans to develop event logs and asked when the CCT started releasing subyearlings. Truscott said April 15, 2019. Kahler said there were detections of Omak and Similkameen fish last week.

IV. Chelan PUD

A. Rocky Reach Dam Turbine Unit C1 and C3 Update (Lance Keller)

Lance Keller said the disassembly of Turbine Unit C1 is progressing as planned. He said the runner and hub might be removed by now or mechanics are very close to doing so, which will allow access to the trunnion seals.

Keller said Rocky Reach Dam mechanical staff are still working with engineers to develop a solution for Turbine Unit C3. He said hydraulically locking the blades into place via governor control or manufacturing new trunnion seals are all still being considered. He recalled discussing during the last HCP Coordinating Committees meeting on March 26, 2019, that the engineered seals designed for Turbine Unit C1 were installed in Turbine Unit C3 and did not work, and Chelan PUD may try another contactor who has previously completed work and provided seals for units at Rock Island Dam. Keller said the path forward for Turbine Unit C3 will not affect the repair schedule for Turbine Unit C1.

Kirk Truscott said he reviewed the meeting minutes from the HCP Coordinating Committees meeting on March 26, 2019, and he reviewed the report by Drs. John Skalski and Richard Townsend (Columbia Basin Research) titled, "Projections of Joint Juvenile/Adult Survival Performance at Rocky Reach Dam under Alternative Juvenile Passage Distributions," (Attachment B), which was distributed to the HCP Coordinating Committees by Kristi Geris on April 5, 2019. Truscott asked about the rationale behind the three scenarios selected to assess survival. Keller said these scenarios were developed to help think about how decreased juvenile yearling Chinook salmon passage via Turbine Unit C3 and the bypass screens (Turbine Unit C1) might translate into changes in juvenile project survival estimates and ultimately the 91% combined juvenile/adult survival metric for Plan Species outlined in the Rocky Reach HCP. Truscott asked how the values 2.5%, 5.0%, and 7.5% were selected (the three scenarios modeled included rerouting 50% of the fish that passed via the bypass screens and 2.5%, 5.0%, or 7.5% of the fish that passed via the surface collector (SC) through the powerhouse and estimating project survival accordingly). Keller said these values were selected after internally discussing and judging the potential decrease in bypass passage routes and attraction flow in the cul-de-sac area with Turbine Units C1 and C3 offline while also considering the modified bypass operations to increase flow through the area, including the following:

Normal Operations (Turbine Units C1 and C3 online)	Modified Operations (Turbine Units C1 and C3 offline)
Individual Fish Passage Routes	
3 turbine routes (via Turbine Units C1, C2, and C3)	1 turbine route (via Turbine Unit C2)
2 bypass screen routes (via Turbine Units C1 and C2)	1 bypass screen route (via Turbine Unit C2)
2 bypass entrance routes (via two entrances to SC)	2 bypass entrance routes (via two entrances to SC)
Considerations	
7 passage routes total	4 passage routes total + 3 additional RRJFBS SC pumps to increase attraction flow from 6 to 6.66 kcfs into the RRJFBS SC entrances (3.33 kcfs on each side) + Increasing Turbine Unit C2 flow from its normal soft-limit set-point of 12.2 kcfs to a soft-limit flow of 15.2 kcfs

Keller said with these considerations, Chelan PUD wanted to know what decrease in survival could possibly result should bypass system fish collection decrease with Turbine Units C1 and C3 not operating. He said Skalski took nautical day and night passage proportions and route specific survivals and applied them to day and night dam survival and then project survival, and those were then multiplied by the specific annual observed adult survival to calculate the combined adult and juvenile survival. Keller said Skalski also included confidence intervals around these results.

Truscott said he is concerned about the attraction flow through the cul-de-sac area. He asked, for example, what if there is a 25%, 40%, or 85% reduction in attraction flow? He asked what can the HCP Coordinating Committees do, notably when turbine units are offline and there is no option to spill. He asked if there is a way to provide additional flow into this area. He also asked if there is a certain amount of flow Chelan PUD is trying to replace. Keller said with Turbine Units C1 and C3 offline and with the modified operations in place, attraction flow into the cul-de-sac area will essentially be reduced by approximately 10,000 cubic feet per second (10 kcfs) compared to normal operations. He added that it is convenient that this issue is occurring during a low flow year. Truscott said his concern is that 40% of fish pass Rocky Reach Dam via the cul-de-sac area and it is important to make sure these fish get there. He added that one could suggest having 30% less attraction flow might translate into 30% less fish passing there. John Ferguson pointed out flow into the bypass is now a much greater proportion of flow passing through Turbine Units C1 to C3 (i.e., bypass flow is competing with flow going into one unit not three). Truscott agreed but indicated his concern is whether fish are being attracted to the cul-de-sac area. Keller said Chelan PUD would take a closer look into attraction flow in the cul-de-sac area. Truscott said he will also contact Keller to further discuss options to increase attraction flow through the cul-de-sac area in the Rocky Reach Dam forebay (near Turbine Units C1, C2, and C3) while Turbine Units C1 and C3 are offline for maintenance.

Ferguson asked if Chelan PUD chooses to hydraulically lock the blades into place as the preferred path forward for Turbine Unit C3, what input is needed from the HCP Coordinating Committees. He asked if the HCP Coordinating Committees need to suggest a particular efficiency setting to maximize survival through the turbine unit. Keller said it is desirable to operate the unit near peak efficiency to avoid wear and tear. He said a unit will run rough until it reaches a setpoint. Jim Craig added that running a unit below peak efficiency will cause cavitation. Keller agreed and added that the way turbine units are designed, the more efficient a unit operates (less cavitation) the better that is for the unit and fish passing through the unit. Truscott said if Turbine Unit C3 comes off and on for load, this could result in operating the unit inefficiently as it ramps up from a dead stop. Keller said he believes if the Turbine Unit C3 blades are hydraulically locked at a fixed point, the unit will be turned on and operated for an extended period of time to reduce starts and stops. He said the unit would be given a hard setpoint based on the blade angle and efficiency curve, which are based on the forebay elevation, and the other turbine units would be adjusted as needed. He added that given the low snowpack estimates for 2019 to date, as well as the fact that Turbine Unit C3 is the next unit to sequentially operate behind Turbine Unit C2, if Turbine Unit C3 were to shut down due to decreased flows, Turbine Unit C2 would be the only operating unit in the Rocky Reach Dam powerhouse (Turbine Unit C2 is the first unit on and last unit off). He said at this point, he believes the most appropriate action item is to provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available.

Tom Kahler asked when Turbine Unit C1 will be returned to service. Keller said August 2019, so the unit will be back online for the 2020 juvenile fish bypass season. Kahler summarized that Turbine Unit C1 will be back in operation in 2020 along with Turbine Unit C2, and Chelan PUD is unsure about Turbine Unit C3? Keller said this is currently correct.

B. Rock Island Dam 2019 Spring Spill (Lance Keller)

Lance Keller said an email notification that spring fish spill was initiated at Rock Island Dam on April 17, 2019, at 00:00 hours was distributed to the HCP Coordinating Committees by Kristi Geris on April 18, 2019. Keller said Chelan PUD monitored the daily index counts at the Rock Island Dam Juvenile Fish Bypass Trap and as of April 16, 2019, Program RealTime indicated all passage estimates for juvenile yearling Chinook salmon, sockeye salmon, and steelhead had remained below 1.0%. He said based on these data, Chelan PUD did not see a need to initiate spill before April 17, 2019, to meet the 95% spill coverage target for spring migrating HCP Plan Species at Rock Island Dam.

Keller said Rock Island Dam will transition from spring to summer spill when subyearlings detections begin at the dam.

C. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said Rock Island Dam mechanics continue to work on the liner in Turbine Unit B4. Keller said the plan is to reuse or repair the liner currently installed in the unit. He said the return-to-service date for Turbine Unit B4 is still July 31, 2019.

D. Subyearling Chinook Salmon SOA (Lance Keller)

Lance Keller said Chelan PUD's current SOA maintaining Rock Island and Rocky Reach subyearling Chinook salmon in Phase III (Additional Juvenile Studies) for up to 3 years expires on September 29, 2019, and Keller said he believes Grant PUD may have a similar agreement in place.

Keller recalled in 2016, the HCP Coordinating Committees and PRCC convened a Subyearling Chinook Salmon Passage Survival Workshop in SeaTac, Washington. He said attendees included various agencies and speakers included Grant, Chelan, and Douglas PUDs, and Dr. John Skalski, among others. Keller said topics and presentations addressed the feasibility of conducting subyearling studies, including discussion on life history, tag technology, and statistical analyses. He said at that time, largely due to subyearlings having varying life history, lack of tag technology, and Skalski's findings, it was concluded that conducting subyearling studies in the Rock Island and Rocky Reach projects was not feasible. He said based on these findings, the Rock Island and Rocky Reach HCP Coordinating Committees approved the SOA maintaining Rock Island and Rocky Reach subyearling Chinook salmon in Phase III (Additional Juvenile Studies) on September 29, 2016.

Keller said to his knowledge, there are now tags available that are smaller in size, but the battery life is still comparable and remains an issue, and Skalski's calculation capability remains the same. Keller said Chelan PUD may propose another SOA maintaining Rock Island and Rocky Reach subyearling Chinook salmon in Phase III (Additional Juvenile Studies) for another 3 years, perhaps coupled with an updated presentation from Skalski.

Tom Kahler said there is still the fundamental problem of the inability to distinguish mortalities from non-migrants. Keller agreed and said a battery with a much longer lifespan than what is currently available is needed to conduct a project-scale study. Kahler said additionally, fish are not migrating, and the HCPs specify studying migrants. He said the hope was to identify migrants based on characteristics, but this has not yet been accomplished.

Kahler also noted that the long-awaited Douglas PUD subyearling report is currently being tech edited and should be available soon. He said the report evolved into something much more than what Douglas PUD was presenting annually during the study, including more analyses. He said the report should be useful for everyone.

Jim Craig said it is beneficial to rehash the ability to study subyearlings every so often. Keller agreed and said there is language in Chelan PUD's current SOA to provide quarterly updates; however, after no changes happened during the first few quarters no further updates were provided or requested by the HCP Coordinating Committee. He said if there is another 3-year SOA, Chelan PUD will be sure to add subyearlings to the agenda each quarter.

John Ferguson suggested adding subyearling Chinook salmon to each agenda through September 2019 to continue this discussion and keep reviewing information as it becomes available. He said this information may include a new SOA from Chelan PUD, the Douglas PUD subyearling report, perhaps a presentation of the data, and possibly a presentation by Skalski. Ferguson said the meeting minutes will then document what the HCP Coordinating Committees discussed and reviewed. He said Chelan PUD can then take this documentation and perhaps include a bulleted list of activities in the background of an SOA and reference documents.

Kirk Truscott said besides the tagging effort conducted by Douglas PUD, there have been no additional studies. Truscott said the CCT are perplexed that subyearlings are being tagged at Gebbers Landing and there are no adults being detected at Bonneville Dam, but there are recaptures of juveniles at detection locations. He said this indicates the fish are moving. He said Douglas PUD conducted tagging efforts from 2011 to 2013 and the CCT have been conducting tagging efforts since 2014, and at some point, someone is going to ask why subyearling Chinook salmon have been maintained in Phase III for 12 years and no studies have been conducted. He said his question is, where are these fish going?

V. HCP Administration

A. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on May 28, 2019, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

HCP Coordinating Committees members who are also members on the PRCC noted that as the calendar falls in May 2019, the PRCC meeting is scheduled 1 week prior to the next HCP Coordinating Committees meeting instead of the day after. Kristi Geris said she will coordinate with Denny Rohr regarding moving the PRCC meeting on May 22, 2019, to May 29, 2019, to dovetail with the HCP Coordinating Committees meeting on May 28, 2019. *(Note: Geris confirmed with Rohr via email on April 25, 2019, that the PRCC meeting on May 22, 2019, has been rescheduled to May 29, 2019.)*

The June 25 and July 23, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

COLUMBIA BASIN RESEARCH

Projections of Joint Juvenile/Adult Survival Performance at Rocky Reach Dam under Alternative Juvenile Passage Distributions

14 March 2019

TO: LANCE KELLER
PUD No. 1 of Chelan County
P.O. Box 1231, Wenatchee, Washington 98801

FROM: JOHN R. SKALSKI AND RICHARD L. TOWNSEND
Columbia Basin Research, School of Aquatic and Fishery Sciences, University of Washington
1325 Fourth Avenue, Suite 1515, Seattle, Washington 98101-2540

1 Introduction

This report summarizes the results of projections of joint juvenile/adult survival values at Rocky Reach Dam under alternative juvenile passage distribution. Using either the 2010 or 2011 acoustic tag data on route-specific yearling Chinook salmon passage proportions and survival (Skalski et al. 2011, 2012), estimates of dam passage survival were recalculated based on three alternative redistribution scenarios. Those three scenarios were as follows:

- Scenario 1. Reroute 50% of the fish that passed via the bypass screens and 2.5% of the fish that passed via the surface collector and route them through the powerhouse and apply average survival of units 1–11 to those fish. Calculate new project survival for each year and standard error.
- Scenario 2. Reroute 50% of the fish that passed via the bypass screens and 5.0% of the fish that passed via the surface collector and route them through the powerhouse and apply average survival of units 1–11 to those fish. Calculate new project survival for each year and standard error.
- Scenario 3. Reroute 50% of the fish that passed via the bypass screens and 7.5% of the fish that passed via the surface collector and route them through the powerhouse and apply average survival of units 1–11 to those fish. Calculate new project survival for each year and standard error.

Dam passage survival was calculated as the route-specific survival values weighted by the route specific passage proportions (Appendix A). Estimates of dam passage survival were calculated separately for day and night and then the values weighted by diel passage proportions (Appendix A). Finally, the joint juvenile/adult survival values were calculated as the product

$$\overset{\circ}{S} = \hat{S}_{\text{DAM}} \cdot \hat{S}_{\text{POOL}} \cdot \hat{S}_{\text{ADULT}}$$

where in both years $\hat{S}_{\text{ADULT}} = 0.999$ ($\widehat{SE} = 0.06$). The adult survival value is based on a conversion rate/survival estimates from the years 2009–2011 (Buchanan and Skalski 2011).

Appendix A defines the formula used to calculate dam passage survival under different redistribution scenarios. Appendix B has the yearling-specific juvenile passage data used in the calculations.

2 Results

The HCP specifies a combined adult juvenile survival benchmark of 0.91. The observed value of dam passage survival in 2010 (i.e., 0.9304) was lower than in 2011 (i.e., 0.9642) (Table 1). Shifting fish distributions from high survival routes (i.e., bypass, spill) to lower survival routes (i.e., powerhouse) uniformly results in lower projected values of dam passage survival in all circumstances (Table 1).

Combining the projected estimates of dam passage survival with pool passage survival and the adult survival, the resulting estimates of joint juvenile/adult survival for yearling Chinook salmon remain ≥ 0.91 under all circumstances (Table 2).

Table 1. Projected values of yearling Chinook salmon juvenile survival ($\hat{S}_{\mathrm{DAM}}$) at Rocky Reach Dam for the years 2010 and 2011 for the three alternative redistribution scenarios.

	Year	
Scenario	2010	2011
Actual annual estimate	0.9304 (0.0088)	0.9642 (0.0091)
Scenario number one	0.9225 (0.0103)	0.9593 (0.0175)
Scenario number two	0.9203 (0.0107)	0.9578 (0.0182)
Scenario number three	0.9181 (0.0112)	0.9563 (0.0188)

Table 2. Projected values of joint juvenile/adult survival ($\hat{S}_o$) for the three alternative redistributions of passage proportions using either 2010 or 2011 year-specific acoustic tag information

	Year	
Scenario	2010	2011
Actual annual estimate	0.9241 (0.0573)	0.9285 (0.0566)
Scenario number one	0.9162 (0.0584)	0.9237 (0.0594)
Scenario number two	0.9140 (0.0583)	0.9223 (0.0595)
Scenario number three	0.9119 (0.0582)	0.9209 (0.0596)

3 Discussion

The results suggest the estimate of joint juvenile/adult survival is rather robust to year effects and the three scenarios we examined. In all six cases examined, the projections remained above 0.91.

Appendix A

Formula used to project dam passage survival for yearling Chinook salmon under alternative redistribution scenarios

$$\hat{S}_{\mathrm{DAM}} = p_D \left[\begin{array}{l} S_{SC}(p_{SC} - \mathbf{\Delta}_{SC}) + S_{BY}\, p_{BY}(1 - \mathbf{\Delta}_{BY}) \\ + \left(\dfrac{2S_{1-2} + 9S_{3-11}}{11} \right) (p_{1-2} + p_{3-11} + \mathbf{\Delta}_{SC} + p_{BY}(1 - \mathbf{\Delta}_{BY}) \end{array} \right]$$

$$+ pN \left[\begin{array}{l} S_{SC}(p_{SC} - \mathbf{\Delta}_{SC}) + S_{BY}\, p_{BY}(1 - \mathbf{\Delta}_{BY}) \\ + \left(\dfrac{2S_{1-2} + 9S_{3-11}}{11} \right) (p_{1-2} + p_{3-11} + \mathbf{\Delta}_{SC} + p_{BY}(1 - \mathbf{\Delta}_{BY}) \end{array} \right]$$

where $\rho_D = 1 - \rho_N$ = proportion of fish passing through the dam during daytime,

S_{SC} = survival probability through surface collector,

S_{BY} = survival probability through bypass,

S_{SP} = survival probability through spillway,

S_{1-2} = survival probability through turbine units 1– 2,

S_{3-11} = survival probability through turbine units 3–11,

p_{SC} = proportion of fish passing through surface collector,

p_{BY} = proportion of fish passing through bypass,

p_{SP} = proportion of fish passing through spillway,

p_{1-2} = proportion of fish passing through turbine units 1–2,

p_{3-11} = proportion of fish passing through turbine units 3–11,

Δ_{SC} = proportion of fish in surface collector shifted to units 1–11,

Δ_{BY} = proportion of fish in bypass collector shifted to units 1–11.

Appendix B

Route-specific passage proportions and survival for juvenile yearling Chinook salmon at Rocky Reach Dam, 2010–2011

Table B1. Estimates of acoustic-tagged yearling Chinook salmon passage proportions at Rocky Reach Dam during nautical day and night periods in 2010. Standard errors in parentheses.

	Passage proportions	
Route	Nautical day	Nautical night
Surface collector	0.4262 (0.0224)	0.6000 (0.0316)
Bypass screens	0.0676 (0.0114)	0.0208 (0.0092)
Units 1–2	0.1906 (0.0178)	0.0833 (0.0178)
Units 3–11	0.3156 (0.0210)	0.2958 (0.0295)

Table B2. Estimates of route-specific survival at Rocky Reach for yearling Chinook salmon during nautical day and night periods in 2010. Standard errors in parentheses.

	Absolute survival	
Parameter	Nautical day	Nautical night
$S_{\text{Surface collector}}$	0.9685 (0.0091)	0.9685
$S_{\text{Bypass screens}}$	0.9231 (0.0424)	0.9891 (0.0152)
$S_{\text{Units 1–2}}$	0.9192 (0.0276)	0.8902 (0.0677)
$S_{\text{Units 3–11}}$	0.8359 (0.0301)	0.9194 (0.0332)

Table B3. Estimates of acoustic-tagged yearling Chinook salmon passage proportions at Rocky Reach Dam during day and night periods in 2011. Standard errors in parentheses

	Passage proportions	
Route	Nautical day	Nautical night
Surface collector	0.3800 (0.0224)	0.2229 (0.0222)
Bypass screens	0.0510 (0.0101)	0.0657 (0.0132)
Units 1–2	0.0488 (0.0099)	0.0657 (0.0132)
Units 3–11	0.4777 (0.0230)	0.5857 (0.0263)
Spillway	0.0425 (0.0093)	0.0600 (0.0127)

Table B4. Estimates of route-specific survival at Rocky Reach for yearling Chinook salmon during day and night periods in 2011. Standard errors in parentheses.

	Absolute survival	
Parameter	Nautical day	Nautical night
$S_{\text{Surface collector}}$	0.9976 (0.0053)	0.9974
$S_{\text{Bypass screens}}$	1.0146 (0.0113)	1.0106 (0.0141)
$S_{\text{Units 1–2}}$	0.9264 (0.0605)	0.8788 (0.0720)
$S_{\text{Units 3–11}}$	0.9469 (0.0199)	0.9464 (0.0216)
S_{Spillway}	1.0146 (0.0113)	1.0106 (0.0141)

Table B5. Day (p_D) and (p_N) passage proportions and pool survival for year 2010 and 2011 for yearling Chinook salmon.

Year	p_D	p_N	S_{POOL}
2010	0.52	0.48	0.9942
2011	0.409	0.591	0.9639

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: June 25, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the May 28, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, May 28, 2019, from 10:00 a.m. to 12:45 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine the following: 1) whether the index samples collected represent overall passage trends based on passive integrated transponder (PIT)-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item II-C).
- Kirk Truscott will contact Lance Keller to further discuss options to increase attraction flow through the cul-de-sac area in the Rocky Reach Dam forebay (near Turbine Units C1, C2, and C3) while Turbine Units C1 and C3 are offline for maintenance (Item II-C).
- Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item II-C).
- Anchor QEA, LLC, will contact Jim Craig to obtain U.S. Fish and Wildlife Service (USFWS) approval of the updated HCP Hatchery Committees and Priest Rapids Coordinating Committee (PRCC) Hatchery Subcommittee email distribution lists (Item III-A). *(Note: Kristi Geris emailed Craig with this request following the meeting on May 28, 2019, and Craig provided USFWS approval of the lists via email on May 29, 2019, as distributed to the HCP Coordinating Committees by Geris that same day.)*
- The HCP Coordinating Committees will begin discussing the necessity and significance of the data behind the Columbia River Inter-Tribal Fish Commission's (CRITFC's) annual request to tag sockeye salmon at Wells Dam during the HCP Coordinating Committees meeting in December 2019 (Item IV-A). *(Note: Kristi Geris added this to the agenda for December 2019.)*

- Douglas PUD will review available PIT-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item IV-B).
- The HCP Coordinating Committees meeting on June 25, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item VI-C).

Decision Summary

- HCP Coordinating Committees representatives present approved the updated HCP Hatchery Committees and PRCC Hatchery Subcommittee email distribution lists, contingent on USFWS approval of the lists (Item III-A). *(Note: Jim Craig provided USFWS approval of the lists via email on May 29, 2019.)*
- Wells HCP Coordinating Committee representatives present approved CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019, with the caveat that approval of the tagging will be reviewed again if low flow and warm water migration conditions develop, potentially affecting adult sockeye salmon survival (Item IV-A). *(Note: Jim Craig provided USFWS approval of this request via email on May 23, 2019.)*

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- The draft *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019, and is available for a 60-day review with edits and comments due to Tom Kahler by Tuesday, July 23, 2019 (Item I-A).

Finalized Documents

- There are no documents that have been recently finalized.

I. Joint HCP Coordinating Committees and PRCC

A. PRESENTATION: Douglas PUD Subyearling Chinook Salmon Report (Tom Kahler)

Tom Kahler shared a presentation titled, "Post-emergence Behavior of Subyearling Summer/Fall Chinook in Wells Reservoir and Implications for the Measurement of Passage Survival through the

Wells Hydroelectric Project" (Attachment B), which was distributed to the HCP Coordinating Committees by Kristi Geris following the HCP Coordinating Committees meeting on May 28, 2019.

Slide 2 of Attachment B

Kahler said this HCP Decision Flow Chart is copied from Section 14 of the Wells HCP. He said the chart indicates that if the combined adult and juvenile project survival cannot be measured for a species and a juvenile dam passage study cannot be conducted, then juvenile dam passage survival can be calculated, and the species can be designated in Phase III (Additional Juvenile Studies). He said this is what was done for subyearling Chinook salmon in 2005.[1]

Kahler recalled subyearling studies conducted by Billy Connor (USFWS) in the Snake River and other U.S. Army Corps of Engineer (USACE) subyearling studies, which prompted Douglas PUD to ask whether subyearlings in the Columbia River behave similarly as in the Snake River. Kahler said in 2009, the HCP Coordinating Committees and PRCC convened a "Subyearling Summit" and invited various guest speakers, including Connor and Eric Hockersmith (Northwest Fisheries Science Center), among others. Kahler said based on these discussions it appeared that subyearlings might be different in the upper Columbia River compared to the Snake River, so Douglas PUD decided to start studying subyearlings in the Wells Reservoir. He said PIT-tagged subyearlings were already being monitored at Rocky Reach Dam, but meaningful analysis was not possible because of the small number tagged individuals. Douglas PUD tagged additional subyearlings to add to this number.

Slides 3 to 4 of Attachment B

Kahler said the photo on slide 3 shows a mixed school of subyearlings, stickleback, and other species. He said in this particular photo, no fish were greater than 60 millimeters (mm) in length. He said several of these schools were observed in the Wells Reservoir during spring, so Douglas PUD decided to attempt a tagging effort. He said summer/fall Chinook salmon spawn in the Okanogan and Methow rivers, and near Chief Joseph Dam, among other locations, and progeny of these spawners occupy Wells Reservoir temporarily.

Slides 5 to 7 of Attachment B

Kahler said the photo on slide 5 shows a beach seining effort. He said Douglas PUD set net-pens in the river and contracted Biomark to conduct the PIT-tagging. He said a tagging station was set up on a barge that was towed to the different tagging locations. He said collected fish were placed in the net-pens overnight to empty their stomachs and were tagged into empty net-pens the next day, then released the following morning.

---

[1] Per the Statement of Agreement (SOA) titled, "Wells HCP Coordinating Committee Summary Agreement Adult Fallback Studies," as approved by the Wells HCP Coordinating Committee on February 22, 2005.

Slides 8 to 10 of Attachment B

Kahler said crews attempted several seining locations in 2011. He said most of the shoreline immediately downstream of Washburn Island was too hard to seine due to high current velocity at this location near the thalweg of the river; however, the short stretch of shoreline closest to the levy was a productive location initially. He said other locations included at the mouth of the Okanogan River up to the Highway 97 bridge and Gebbers Landing, which is a high bluff with a sand and cobble beach, with little debris. He said all locations had bycatch except Gebbers Landing, and crews ended up abandoning all locations except Gebbers Landing.

Kirk Truscott asked about the species of bycatch encountered. Kahler said there were juvenile whitefish, suckers, stickleback, and pikeminnow, to name a few. Truscott asked if any steelhead were encountered. Kahler said not often, but sometimes a yearling, smolt, or triploid were encountered. He said most fish were juveniles. He said some juvenile kokanee were encountered, as well.

Kahler said crews also seined at the mouth of the Methow River; however, there was a lot of debris and high river flow. He said crews also tried downstream near Wells Dam, but never found a productive location. He said in 2012, at river left near Wells Dam, there was one location similar to Gebbers Landing in terms of beach characteristics. He said this location was productive; however, it was not as productive as Gebbers Landing. He said sampling this site resulted in a lot of tagged fish being recaptured.

Slide 11 of Attachment B

Kahler said, in summary, fish were first detected at Rocky Reach Dam about 3 to 6 days after release. He said Douglas PUD seined through the second week in July; he noted that by the end of seining, subyearlings were difficult to collect. He said the total number tagged equaled nearly 51,000 fish over the 3-year effort. He said detections at RRJ (Rocky Reach Dam Juvenile Bypass System) were fairly consistent, with the most detections occurring in 2013. He said the percent detected at RRJ ranged from approximately 6% to 11% of total tagged fish per year. He also noted the high number of unique detections when including all detection sites combined.

Andrew Gingerich said Douglas PUD also conducted scoping efforts to determine when fish were available in the Wells Reservoir each year. He said this table just summarizes what was tagged. Kahler agreed and said the tagging threshold was 60 mm. He said the contractor tagged down to 58 mm, but did not tag many at that size. He said by 2013, Douglas PUD set the lower size-at-tagging threshold firmly at 60 mm. Kahler said, as Gingerich explained, crews conducted sampling to monitor how large the fish were and when the mean fish size reached 60 mm, Biomark would come out and start tagging.

Truscott asked how the unique detections for subyearlings compared to yearling Chinook salmon. Kahler said he has not examined that comparison; however, it would be easy to do by reviewing the Wells Project 2010 Survival Verification Study.

Slides 12 to 15 of Attachment B

Kahler said again, crews started seining long before tagging was initiated. He said when sufficient numbers of taggable-sized fish were available, the tagging effort would commence. He said in 2011, tagging commenced about the third week of June. He said in 2012, tagging started 1 week later compared to the previous year because fish were too small to tag. He said in 2013, tagging started earlier because the fish sizes were similar to 2011.

Kahler said in 2014, although the Colville Confederated Tribes (CCT) took over tagging efforts this year, Douglas PUD conducted another scoping effort to collect another year of data on early season fish size and availability.

Slides 16 to 17 of Attachment B

Kahler said crews were seeing swim-up fry in May. He noted that in 2012, crews were collecting fish less than 45 mm into the second week of July and fish less than 55 mm at the end of July. He questioned where these fish came from. Truscott said mainstem fish spawn in November and December, and he asked if there were more late small fish at Washburn Island compared to Gebbers Landing. Gingerich said fish collected at Washburn Island may be from mainstem spawners. He said these fish were not available as long as at the Gebbers location. He said 2 to 3 weeks into tagging the Washburn fish were no longer available. Kahler said perhaps these could be spring Chinook salmon that have been washed out from the upper watershed.

Slides 18 to 20 of Attachment B

Kahler said in 2011, detections at downstream projects peaked a few weeks after tagging commenced. He noted the multi-modal distribution of the detection pattern continuing downstream. He said once fish reached MCN (McNary Dam), the downstream migration rate increased dramatically. He noted that fish were being detected into November at downstream projects. He said 2012 data are similar, except that the multi-modality pattern at RRJ turned into a bimodal distribution at downstream projects. He said one fish was detected into the second week of December.

Peter Graf (Grant PUD) asked if Douglas PUD looked at whether study fish emigrated as yearlings. Kahler said at RRJ, there was only one yearling detected (tagged in 2011), and for downstream locations, there were 3 fish detected as yearling migrants. He added that this was surprising considering the persistent rate of reservoir-type juveniles identified by the scales of returning adults.

Truscott said it seems in the past 6 to 7 years, there has been a reduction of adults returning with reservoir-type scale patterns. Kahler agreed.

Slide 21 of Attachment B

Kahler said this slide summarizes travel rates in kilometers per day. He noted the lowest flow year was also the slowest rate.

Slides 22 to 27 of Attachment B

Kahler said in 2011, travel time and tagging length data appeared to show a break at fish tagged at 87 mm fork length, where fish less than 87 mm took longer to migrate and fish greater than 86 mm were faster. He said when these two size classes were compared, 2011 data showed that fish tagged at 87 mm or larger were five times faster in emigration compared to fish tagged at less than 87 mm. He said additionally, both size classes accelerated as they moved downstream from McNary Dam, but the larger fish showed greater acceleration. He said, however, 2012 data showed a similar pattern but not as pronounced; and 2013 data showed not much difference at all in emigration rate between the two size classes downstream from McNary Dam.

Graf asked if the larger fish were tagged later, and Gingerich said this was generally the case. Kahler said there is a general increase in size over time, but the increase was not as large as expected. He said the mean fish size at tagging increased from 70 to 80 mm over the tagging period in all 3 years.

Slide 28 of Attachment B

Kahler said when comparing detection rates by size class, the data indicate larger fish have a significantly higher chance of being detected compared to smaller fish.

Slides 29 to 36 of Attachment B

Kahler said travel times compared to tagging length were variable from 2011 to 2013. He said travel times for all years showed that fish showed a diversity of travel times to RRJ, with some fish emigrating rapidly (within 20 days), and others showing protracted residency (greater than 20 days). Those residing longer tended to comprise the smaller two-thirds of the size distribution, while those emigrating rapidly comprised the entire size range. This observed break between categories of travel time to RRJ varied by tagging week, ranging from 15 to 20 days, but in the dataset combining all weeks, the break was at 20 days.

Slides 37 to 38 of Attachment B

Kahler said during Week 1 of 2013 tagging, the distribution of fish sizes and travel times were similar at the upstream and downstream sites. He said by Week 3, there was an interesting shift of quite a few larger fish near the Wells Dam forebay exhibiting longer travel times.

Slides 39 to 41 of Attachment B

Kahler said travel times, post-tagging, from release to RRJ were compared for fish with travel times less than or equal to 20 days versus greater than 20 days. He said a high proportion of fish tagged in Week 1 exhibited longer travel times, but the proportions of fish with short or long travel times shifted over the tagging period such that a greater proportion fish tagged in Week 3 exhibited short travel times. He said there were also a number of fish recaptured in Wells Reservoir before emigrating to RRJ; therefore, post-recapture travel times to RRJ for fish recaptured in Wells Reservoir were also reviewed. He said the proportions of recaptured fish with travel times of less than or equal to 20 or greater than 20 days matched that in the entire population of fish detected at RRJ. He said fish with residence times less than 7 days between tagging and recapture manifested almost the same proportion of individuals with travel times greater than 20 days as the population of fish detected at RRJ; however, fish with residence times greater than or equal to 7 days between tagging and recapture had very different post-release travel time proportions (skewed toward long travel times). He added that these data indicate that fast emigrants to RRJ are not fish that had already resided in Wells Reservoir for a week or more prior to emigration to RRJ.

Slides 42 to 43 of Attachment B

Kahler said length at tagging of all tagged fish was compared to length at tagging of returning adults. He said the mean length at tagging of returning adults is significantly larger than that of all tagged fish, suggesting higher survival for larger fish. He said additionally, travel times from release to RRJ for all tagged fish were compared to travel times from release to RRJ for returning adults. He noted the bimodal distribution and said travel times between the two groups were not statistically different, suggesting there is no survival advantage to a lengthy residence time or rapid emigration. Graf summarized that returning adult fish are generally larger at tagging but not generally faster emigrants, and Kahler said this is correct.

Slide 44 of Attachment B

Kahler said fish growth in mm per day was compared across 2011, 2012, and 2013. He noted that inaccurate measuring during the 2011 and 2012 effort was corrected in 2013. He said generally, post-tagging, growth rates were relatively low for the first few days, but gradually increased so that by two weeks post-tagging growth rates typically exceeded 0.8 mm per day. He said by 20 days post-tagging, growth rate generally exceeded 1 mm per day, which is similar to estimated growth rates of untagged fish. He said that the lack of any evidences of a relationship between length at tagging and growth rates, indicates that the low growth rate post-tagging seems to result from the tagging process rather than from tag burden. He explained that seined fish were held in a pen, tagged, held again for recovery (from anesthesia), and then released. He said it takes a few days for a fish to recover from the tagging process, since they can’t freely feed during the threeday period.

Slides 45 to 53 of Attachment B

Kahler reviewed passage timing and corresponding fork-length data from historical fyke-net efforts compared to recent beach-seine efforts. He noted on slide 48 that in early June there were quite a few fyke-net catches and he suspects these were entrained fry, notably because the timing was around the typical peak of the freshet. He also pointed out the larger subyearlings in the fyke-net catches and speculated that these may be active migrants and noted that fish of those lengths were not well represented in the beach-seine catches. He said on slide 49, in the second and third weeks of June, which is the timing when tagging efforts commenced in 2011 to 2013, the data start showing alignment of distributions between fyke-net and beach seining efforts, but the beach-seine catches underrepresent the larger fish caught in the fyke-nets.

John Ferguson noted, from slide 50 to 51, the shift to the right where it seems the fyke-net effort at Wells Dam was collecting fish that had been in the reservoir longer compared to the beach seining efforts. Kahler said these data could be interpreted a number of ways. He said the beach seining efforts are not sampling everything that passes Wells Dam. Truscott said there are also two different populations. He said the beach seining efforts are more heavily biased to Gebbers Landing, whereas those fish in the fyke-net catches might be influenced more from the Methow River. Kahler said in retrospect, it would have been beneficial to collect genetic samples. Kahler emphasized the important point that the beach-seining effort was unsuccessful in capturing the larger fraction of subyearlings in the reservoir as indicated by the fact that the length distribution of beach-seine catches encompassed approximately the smaller one-half of the length distribution of fyke-net catches.

Kahler noted, on slide 52, that the beach seining efforts struggled to find fish; and on slide 53, in the last weeks of fyke-netting in August, the sample size decreased significantly.

Slides 54 to 55 of Attachment B

Kahler said the graphic on slide 54 compares the lengths of fish during Weeks 28 to 29, captured by night purse seining, mostly night fyke-netting, and day beach seining. He said the fyke-net and 1984 purse-seine data match, and though the 1983 purse-seine data align more closely with the beach-seine data, it still represents a population of larger fish than that represented in the beach-seine catches. He noted that the beach seining efforts were unable to collect larger fish compared to the other efforts, and also captured smaller fish not observed in the other efforts. He said slide 55 shows that neither daytime beach seining nor the capture of an offshore school by beach seining were able to catch fish within the size range of those captured by nighttime purse seining at approximately the same river mile. He noted that while the purse seining succeeded in obtaining large fish, it yielded very small numbers of catch during this time of the year (Week 27).

Slide 56 of Attachment B

Kahler said this slide shows the progression in fork length at tagging of fish captured in fyke-nets compared to beach-seined fish. He noted that the mean fork length is smaller, and the progression rate is lower in beach-seined fish compared to fish captured in fyke-nets.

Slides 57 to 59 of Attachment B

Kahler said these next slides show travel times by fish length at tagging for fish detected at WEJ (Wells Dam Bypass Bay Sample) and RRJ in 2017 and 2018. He said because WEJ was installed after the Douglas PUD tagging effort, these data are CCT-tagged fish. He said 30 of 32 fish were detected at WEJ within 20 days post-release. He said when proportional travel times are added to these data, the extrapolated travel times from WEJ to RRJ are mostly less than or equal to 20 days. He noted that all of the 7 fish captured at WEJ and RRJ were detected at WEJ within 10 days of release, and all but 2 spent most of their total travel time in the Rocky Reach Reservoir.

Slide 60 of Attachment B

Kahler said this slide shows the time of day fish were detected at WEJ compared to fish detected at RRJ. He said while about 65% of fish detected at WEJ were during the dusk-to-dawn timeframe, the actual times differed compared to the group at large detected at RRJ. Ferguson asked if these data differed from the fyke-net data, and Kahler said yes but the fyke-net data were individual events and not continuous sampling.

Slide 61 of Attachment B

Kahler said this slide was presented during the Subyearling Workshop held in 2016 and shows the estimated probability of mortal injury for certain sized fish carrying a certain sized tag when passing through a simulated turbine. He said according to this graph, a 60-mm Chinook salmon carrying a PIT-tag weighing approximately 0.1 gram would have just under a 20% probability of mortal injury at a given ratio of pressure change. He said the current Juvenile Salmon Acoustic Telemetry System (JSATS) tag weighs 0.22 gram, and in a 60-mm fish this tag burden would result in a 100% chance of mortality based on these studies. He said Pacific Northwest National Laboratory (PNNL) has recently developed a new ELAT (eel and lamprey acoustic tag) that is almost the same size and mass as a PIT-tag, only with a 20-day battery life. He said PNNL has reached a 35-day battery life in some ELATs; however, even if the ELAT battery life improves, there will still be sample size limitations.

Slides 62 to 68 of Attachment B

Kahler reviewed the conclusions and acknowledgements.

Discussion

Truscott thanked Douglas PUD for the effort in developing this presentation and report. He said it is interesting that fish passing Wells Dam (the fyke-net catches) are considerably larger than fish collected during beach seining efforts. Gingerich suggested resolving this question by taking fish detected at RRJ and applying a growth rate estimate based on what is known about growth in the Wells Reservoir. Kahler agreed, recalling that almost all 32 fish detected at WEJ were within 20 days of release, and within 15 days post-release fish growth was up to 0.8 to 1 mm per day. He said this curve can be applied to fish detected at RRJ to estimate fish size at Wells Dam.

Graf asked if there is a population of untagged fish sampled at RRJ and suggested perhaps comparing the run-at-large to PIT-tagged fish at RRJ to determine whether bias exists. Gingerich said he does not believe it is accurate to say the run-at-large is completely measured; for example, fry are only enumerated. Lance Keller agreed and said fry are enumerated and the species is recorded. He said for subyearlings exceeding the fry size threshold, a subsample of lengths and weights are collected each day until 100 fish of each species encountered are collected; therefore, not every fish is measured. He added that for recaptures, only lengths are recorded. Graf noted that the Entiat River produces a different fish. Gingerich also noted that the sample at RRJ is conducted during the morning hours and fish availability will be limited based on when subyearlings pass RRJ compared to when the sample is conducted. Keller said Chelan PUD conducted all-day sampling for 3 years and most of those fish were dominated by hatchery fish and subyearlings would show up after that initial hatchery pulse.

Ferguson noted the diverse behavior in the Wells and Rocky Reach reservoirs, but by the time fish reach MCN migration times are quick. He questioned how far upstream from MCN does this behavior start. Graf said Tom Desgroseillier (formerly USFWS, now WDFW) studied this with Entiat River fish and he found there was also a lot of diversity upstream of MCN before sorting out. Graf added that there were more than a few fish that overwintered near MCN.

Kahler said Dennis Dauble (PNNL, retired) conducted night sampling at a location in the Hanford Reach and most subyearling Chinook salmon captured were in fast, deep water and near the bottom, and only a fraction were caught off the shoreline. *(Note: Kahler later clarified the sampling method was fyke-netting with nets set along a cross-section of the river at various depths. Kahler said Dauble's team also beach-seined in nearshore areas; however, Kahler is unsure whether these activities were conducted during nighttime hours.)*

Truscott recalled requirements in the HCPs to study active migrants; however, he said impacts of a project on a population may apply to more than just active migrants. He said it seems from a population management standpoint, it might not be the best decision to only study active migrants.

Kahler said prior to the development of the Mid-Columbia River dams, records indicate that subyearlings emigrated rapidly and did not have lengthy residence times upriver. He said once the dams and projects were developed, it created a different river and fish have adapted to a reservoir environment. He questioned whether this is a good or bad thing for fish populations. He said perhaps the reservoir environment is an overall better rearing strategy verses immediately emigrating out to the estuary and around those predators.

Ferguson said the draft *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Geris on May 24, 2019, and is available for a 60-day review with edits and comments due to Kahler by Tuesday, July 23, 2019. Kahler said he has already found a handful or typos that he will correct, including on page 38, Table 12, he said the sample sizes for less than 7 days and 7 or more days should be flipped.

B. Subyearling Chinook Salmon Studies (All)

John Ferguson recalled discussing during the last HCP Coordinating Committees meeting on April 23, 2019, Chelan PUD's current Statement of Agreement (SOA) maintaining Rock Island and Rocky Reach subyearling Chinook salmon in Phase III (Additional Juvenile Studies) for up to 3 years, which expires on September 29, 2019. Ferguson asked if Chelan PUD has any updates on this. Lance Keller said no, that Chelan PUD would like to take more time to review Douglas PUD's report.

Keller said in Douglas PUD's study, the 2011 travel time and tagging length data showing a break at fish tagged at 87 mm fork length was promising. Andrew Gingerich agreed and recalled thinking the same thing until the additional years of data did not show the same pattern. Kirk Truscott noted that 2011 and 2012 were high water years, and suggested reviewing data for other high water years to determine if there may be an effect from high flow. He also noted the lack of large fish that are tagged. Tom Kahler recalled discussing, during the 2016 Subyearling Workshop, using a lampara net to collect larger fish. Kahler said Geoff McMichael (Mainstem Fish Research) attempted this but was unsuccessful at capturing the numbers of fish necessary for a study.

Gingerich said perhaps the fish collected during fyke-netting were feeding heavily in increasing water temperatures resulting in increased growth rates, and then these rapidly growing fish are what was collected during fyke-netting and are omitted from the beach-seining catches.

Truscott asked if Douglas PUD sacrificed any fish to determine how well the stomachs were evacuated. Kahler said no and asked if the CCT did. Truscott said no.

Truscott said he is curious about the 20,000 tagged subyearlings from the CCT tagging effort that have not returned as adults. Kahler said the CCT did take over tagging right when ocean conditions were going bad. Ferguson asked about the mean fish size at tagging. Truscott said fish were tagged down to 60 mm. He said some fish have been detected at RRJ and MCN, so the fish are not dying right away. Ferguson said based on a recent study in the Yakima River Basin (Knudsen et al. 2009), delayed smolt-to adult survival suppression from PIT-tagging is about 30% to 40%.

II. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Lance Keller added a Rock Island Dam bypass incident
- Keely Murdoch added an introduction to the new Yakama Nation (YN) HCP Coordinating Committees Alternate Representative, Brandon Rogers

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft April 23, 2019 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. HCP Coordinating Committees members present approved the April 23, 2019 meeting minutes, as revised. *(Note: Jim Craig provided USFWS approval of the minutes via email on May 23, 2019.)*

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on April 23, 2019, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on April 23, 2019):*

- *Lance Keller will review subyearling Chinook salmon sampled at the RRJSF during the summer spill season at Rocky Reach Dam, to determine: 1) whether the index samples collected represent overall passage trends based on PIT-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in DART (Item I-C).*
  Keller said a diel graph is undergoing internal review, which shows PIT-tagged subyearlings arriving at Rocky Reach Dam. He said the data indicate a large proportion of nighttime passage and a lower proportion of daylight passage. He recalled the question was about the timing of the sample period at the RRJSF, and he said Dr. John Skalski (Columbia Basin Research) indicated that so long as the index sample is conducted at the same time each year, the data are representative and comparable among years. This action item will be carried forward.

- *Lance Keller will inquire internally about the reasoning behind taking downstream-migrating Pacific lamprey at the Rocky Reach Juvenile Fish Bypass System (RRJFBS) and releasing these fish at an upstream location (Item I-C).*
  Keller said he discussed this with Steve Hemstrom who indicated this was a decision made within the Rocky Reach Fish Forum (RRFF). Keller said the RRFF decided that a healthy adult Pacific lamprey encountered in a RRJFBS sample could be a fallback and should be returned upstream of the dam. He suggested moving this topic to the RRFF if it warrants further discussion. Kirk Truscott said there does not seem to be much Pacific lamprey in-ladder passage prior to spring emigration trapping, which is why he is skeptical about identifying these as fallbacks. Keller said crews closely assess whether the Pacific lamprey is healthy or spawned out, and only healthy Pacific lamprey are released upstream. Truscott asked about when Pacific lamprey are migrating through the fish ladders at Rocky Reach Dam, and Keller said these data can be reviewed and compared to the capture dates at the sampling facility. John Ferguson suggested taking this topic to the RRFF.
- *Tom Kahler will distribute recent reports by CRITFC that summarize findings from their sockeye salmon monitoring efforts (Item I-C).*
  Kahler provided a CRITFC report covering 2016 and 2017 tagging efforts to Kristi Geris on May 20, 2019, which Geris distributed to the HCP Coordinating Committees that same day; the 2018 report will be available in late summer 2019.
- *Tracy Hillman will further discuss with the HCP Hatchery Committees and PRCC Hatchery Subcommittee about combining the committees' email distribution lists and will report back to the HCP Coordinating Committees regarding the path forward (Item II-A).*
  Hillman provided updated HCP Hatchery Committees and PRCC Hatchery Subcommittee email distribution lists for HCP Coordinating Committees approval to Kristi Geris on May 20, 2019, which Geris distributed to the HCP Coordinating Committees that same day.
- *Kirk Truscott will contact Jeff Fryer (CRITFC) to obtain clarification on questions the CCT have about CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 (Item III-A).*
  Truscott said he spoke with Fryer and will further discuss this during today's meeting.
- *Kirk Truscott will contact Lance Keller to further discuss options to increase attraction flow through the cul-de-sac area in the Rocky Reach Dam forebay (near Turbine Units C1, C2, and C3) while Turbine Units C1 and C3 are offline for maintenance (Item IV-A).*
  This action item will be carried forward.
- *Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item IV-A).*
  This action item will be discussed during today's meeting and will also be carried forward.

- *Kristi Geris will coordinate with Denny Rohr (PRCC Facilitator) regarding moving the PRCC meeting on May 22, 2019 to May 29, 2019, to dovetail with the HCP Coordinating Committees meeting on May 28, 2019 (Item V-A).*
  Geris confirmed with Rohr via email on April 25, 2019, that the PRCC meeting on May 22, 2019, has been rescheduled to May 29, 2019.

III. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on May 15, 2019 (*note: joint HCP Hatchery Committees/PRCC Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Streamlining HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings (joint)*: The HCP Hatchery Committees reviewed, updated, and approved the meeting protocols. The protocols are a living document and can be updated anytime. Hillman said these protocols will likely be reviewed annually. The HCP Hatchery Committees also reviewed, updated, and approved two email distribution lists. A primary list includes individuals who will receive all communications, and a secondary list includes individuals who will receive only final products. The HCP Hatchery Committees are now requesting HCP Coordinating Committees approval of these two distribution lists. John Ferguson said these lists were distributed to the HCP Coordinating Committees by Kristi Geris on May 20, 2019, which is just short of the required 10 calendar days for decision items, per the HCPs. Ferguson said if the HCP Coordinating Committees representatives present are ready to vote now, Anchor QEA will contact Jim Craig to obtain USFWS approval of the email distribution lists via email. HCP Coordinating Committees representatives present approved the updated HCP Hatchery Committees and PRCC Hatchery Subcommittee email distribution lists, contingent on USFWS approval of the lists. *(Note: Geris emailed Craig following the meeting on May 28, 2019, and Craig provided USFWS approval of the lists via email on May 29, 2019, as distributed to the HCP Coordinating Committees by Geris that same day.)*
- *National Marine Fisheries Service (NMFS) Consultation Update (joint)*: NMFS is completing the Finding of No Significant Impact for the Steelhead and Summer Chinook Salmon Environmental Assessments (EAs). NMFS received no major comments from the public on the Steelhead or Summer Chinook Salmon draft EAs. Permits for the programs are under review by General Council.
- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on June 19, 2019.

Hillman said the HCP Tributary Committees met on May 8, 2019; participated in site tours on May 9, May 13, and May 14, 2019; and held a conference call on May 21, 2019, to discuss observations from the site tours:

- *General Salmon Habitat Program (GSHP) Draft Proposals*: The HCP Tributary Committees received 18 GSHP draft proposals. These are cost-share proposals with the Salmon Recovery Funding Board. The HCP Tributary Committees identified 10 projects that did not warrant a full proposal, because the project did not have strong technical or biological merit or were not cost-effective (low benefits per cost). The HCP Tributary Committees solicited full proposals from seven projects, which are due on June 28, 2019. The proposed projects are in the Wenatchee, Entiat, and Methow rivers basins.
- *Napeequa Side Channel Connection Project*: One of the 18 GSHP applications reviewed was from Cascade Columbia Fisheries Enhancement Group and was titled, "Napeequa Side Channel Connection Project." The purpose of the project is to remove a culvert and associated fill to restore hydraulic connectivity to a side channel along the lower Napeequa River, a tributary to the White River. This action will improve juvenile steelhead and spring Chinook salmon survival and productivity by providing access to an important spring-fed side channel. The total cost of the project is $58,290. After careful review of the proposal, the Rocky Reach HCP Tributary Committee elected to contribute $49,399 to the project (the project has a cost share of $8,891).
- *YN Initiation of Dispute Resolution*: Hillman said this item occurred after the HCP Tributary Committees meeting on May 8, 2019. On May 23, 2019, the YN submitted a letter to the HCP Tributary Committees Chairman indicating the YN are formally initiating the dispute resolution process as defined in Section 11 of the Anadromous Fish Agreement and HCPs. Hillman said, to be clear, the YN are not disputing the HCP Tributary Committees decision to not fund the Scaffold Camp #2 Acquisition Project; rather, the dispute is only about the HCP Tributary Committees' rejection of the YN's SOA titled, "Basis for Decision Making in HCP Tributary Committees." The HCP Tributary Committees have 20 days from the receipt of the dispute to review and discuss the dispute before elevating the dispute to the HCP Coordinating Committees. Hillman said the HCP Coordinating Committees will then have 20 days to resolve the dispute or elevate the dispute to the HCP Policy Committees, who will then have 30 days to resolve the dispute. Ferguson said he will coordinate with Hillman regarding scheduling to align the HCP Coordinating Committees review of the dispute during the regularly scheduled HCP Coordinating Committees meeting on June 25, 2019. Ferguson asked Hillman if the HCP Tributary Committees plan to convene to discuss the dispute prior to the next scheduled HCP Tributary Committees meeting? Hillman said when the HCP Tributary Committees voted on the SOA, members made it clear this dispute could not be resolved within the HCP Tributary Committees. He said he distributed to the HCP Tributary

Committees a packet of information for review. He said if these materials change minds about resolving the dispute, the HCP Tributary Committees will convene by conference call. Hillman said, however, at this point, he does not believe the outcome will change over another conference call. Ferguson suggested the HCP Coordinating Committees start thinking about this, including discussing the dispute with respective HCP Policy Committees representatives and perhaps review the meeting minutes to remind themselves of the discussions. Keely Murdoch said reviewing the HCP Coordinating Committees meeting minutes might be useful; however, the dispute is about an SOA and issue paper that the HCP Coordinating Committees did not receive. She said the HCP Coordinating Committees meeting minutes focus more on the Scaffold Camp #2 Acquisition Project, which is not what the dispute is about. Ferguson agreed and said the SOA and issue paper will be included in the package received from the HCP Tributary Committees.

- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on July 16, 2019. Hillman said in June 2019, the HCP Tributary Committees will be attending GSHP proposal presentations and will not officially meet unless something arises with the dispute.

IV. Douglas PUD

A. DECISION: CRITFC's Annual Request to Tag Sockeye Salmon at Wells Dam in 2019 (Tom Kahler)

CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019 was distributed to the Wells HCP Coordinating Committee for review by Kristi Geris on February 20, 2019. There was an action item for Kirk Truscott to contact Jeff Fryer to obtain clarification on questions the CCT have about CRITFC's request. Tom Kahler asked Truscott if the CCT concerns were addressed by Fryer.

Truscott said he and Fryer discussed the significance of the data. Truscott said for 2019, the CCT will approve tagging; however, he said the HCP Coordinating Committees need to have a serious discussion about whether these data are still necessary. He asked, what management decisions are being made based on tagging sockeye salmon at Wells Dam? He said the CCT is conducting a qualitative assessment for almost all salmonid species except spring Chinook salmon and steelhead, and Fryer's reports are the only source of sockeye salmon data available, which has been useful. He asked, however, how many years of these data are actually needed? He said at this point, he believes handling these fish less is more important than the data.

John Ferguson asked when Truscott would like to start these discussions, and Truscott said in December 2019. The HCP Coordinating Committees will begin discussing the necessity and significance of the data behind CRITFC's annual request to tag sockeye salmon at Wells Dam during the HCP Coordinating Committees meeting in December 2019. *(Note: Geris added this to the agenda for December 2019.)*

Kahler said Fryer has mentioned potentially tagging fewer sockeye salmon during future events, maybe around 300 fish as (opposed to 800 fish). Truscott added that it is unknown how this water year will shape up. He said with the warmer weather it may be wise to revisit approval of this request if there are issues with water temperature and river flow. Andrew Gingerich noted that the Okanogan River is already very low this year. He said if the CCT are concerned about adult escapement, the Okanogan River may be tough by the time sockeye salmon arrive.

Wells HCP Coordinating Committee representatives present approved CRITFC's annual request to tag sockeye salmon at Wells Dam in 2019, with the caveat that approval of the tagging will be reviewed again if low flow and warm water migration conditions develop potentially affecting adult sockeye salmon survival. *(Note: Jim Craig provided USFWS approval of this request via email on May 23, 2019.)*

Ferguson suggested, if needed, the CCT request revisiting approval of tagging sockeye salmon at Wells Dam in 2019, during a future HCP Coordinating Committees meeting. Truscott agreed. *(Note: on May 29, 2019, Geris notified Fryer of the Wells HCP Coordinating Committee approval of CRITFC's request, including the caveat to revisit the approval pending river conditions.)*

B. Wells Dam Bypass Operations Update (Tom Kahler)

Tom Kahler said a Summary of Wells Dam Bypass Operations in April 2019 was distributed to the HCP Coordinating Committees by Kristi Geris on May 10, 2019. Kahler said the summary explains Wells Dam bypass non-compliance events that occurred in April 2019. He said he has already discussed these events with each Wells HCP Coordinating Committee representative, and each representative said they planned to review the summary document. Kahler asked if there were questions about the summary or if the Wells HCP Coordinating Committee wants him to walk through what happened.

Kirk Truscott said what is most important is that there is follow-through to make sure the same thing does not happen again. He said Douglas PUD developed a good roadmap to minimize the chances of something like this reoccurring.

Keely Murdoch asked if there is any idea of how these non-compliance events affect fish passage survival? Kahler said it is unknown how many fish were present and what passage routes were used when these events occurred. He said he knows there were hatchery releases in the water around this time, including Winthrop, Methow, Chewuch, and Twisp river fish. Truscott suggested reviewing PIT-tag data for abnormally low values compared to past years. Murdoch cautioned there is high variability in these data. Truscott agreed but said it may be an exercise worth doing. Murdoch asked if Truscott is suggesting calculating smolt-to-smolt survival to Rocky Reach Dam or McNary Dam, and Truscott said to McNary Dam would provide more data points. Truscott suggested reviewing the Annual Program Review reports. He said these reports are cumulative and are listed by release group. Kahler asked about the release dates for CCT hatchery fish. Truscott said fish were semi-volitionally released the week of April 15, 2019, and by April 18, 2019, most fish were forced out. Kahler said Douglas PUD will review available PIT-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project.

V. Chelan PUD

A. Rocky Reach Dam Turbine Unit C1 and C3 Update (Lance Keller)

Lance Keller said the hub of Turbine Unit C1 is now completely disassembled and work is progressing. He said he has no measurable updates on Turbine Unit C3. He recalled last month describing the following: 1) installing in Turbine Unit C3 the engineered seals designed for Turbine Unit C1, without success; 2) specific engineered seals designed for Turbine Unit C3, which should have arrived last week; and 3) investigating hydraulically locking the blades into place via governor control.

Kirk Truscott asked how long does it take and what is involved to evaluate hydraulically locking the blades into place? Keller said this involves a modeling exercise, and Chelan PUD has contracted an external consulting firm from Italy who specializes in these types of repairs and modifications. He said a mechanical installation is needed to hold the blades in place and it is extremely important that the blade angle is accurate to not cause runaway. He said the only way to stop runaway blades is to place headgates in to stop the unit, which is very serious and is why this evaluation also includes a risk assessment.

B. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said Rock Island Dam mechanics are progressing on Turbine Unit B4. He said work is completed on the discharge liner and the new stainless-steel portion of the liner will be installed next. He said as mechanics continue disassembly of Turbine Unit B4, components of the unit are being inspected for condition and expected lifespan. He said parts initially planned for re-use are now being identified as needing replacement, which has pushed back the estimated return-to-service date from July to November 2019. He said, for example, mechanics found structural issues in the wicket gate control that regulates the amount of water coming into the unit. He said this ring sits on top of the wickets gates and controls all gates. He said whether the unit undergoes an extensive repair or complete rebuild, the schedule will have to be moved out. He said at this time, he is unsure how Turbine Unit B4 will affect the remaining schedule.

Kirk Truscott asked if there is concern the other units might be in the same condition? Keller said Chelan PUD will definitely inspect the other units; however, mechanics do not have the ability to do this at this level until the unit is disassembled. Truscott asked if Chelan PUD plans to order additional parts now in case these same issues are discovered in the other units, opposed to losing 3 to 4 months per unit. Keller said he expects this will be the case, and he added that some time may be gained with the other units from learning efficiencies gained from the maintenance of Turbine Unit B4.

C. Rock Island Dam Bypass Incident (Lance Keller)

Lance Keller said in late-April and early May 2019, Chelan PUD identified and resolved an issue at the Rock Island Dam bypass. He said in late April 2019, steelhead collected at the bypass dropped below 100 fish per day, yet there was a slight increase in the mortality rate. He said on April 20, 2019, the mortality rate was 1.3% (2 mortalities out of 109 fish collected that day). He said on April 25, 2019, the mortality rate was 5.8% (4 mortalities out of 69 fish collected that day). He said what was perplexing was these fish were not fresh mortalities and it was obvious these fish were not dying in the trap. He said additionally, all fish had descaling on one side of the body. He said crews inspected the gates that control river flow into the trap; however, no issues were identified. He said additional mortalities were discovered in the trap with the same characteristics as the others (i.e., not fresh and descaling on one side). He said crews then suspected an issue within the traveling water screen portion of the system. He said there was an increase in the time period when the screens in this system are sprayed and based on the descaling fish might be becoming impinged on the screens. He said crews isolated all flow from the traveling water screen system and there was a subsequent decrease in mortality rate to 1.09% on April 30, 2019.

Keller said on May 1, 2019, a fishway attendant identified another potential source of the fish mortalities in the R11 gate, which is one of the gates that controls river flow into the trap from the Powerhouse 2 portion of the system. He said a drain plug was removed from the gate during the adult fishway maintenance period and inadvertently was not reinstalled (this was overlooked during the first inspection of the gate). He said crews attempted to reinstall the plug, operated R11 to the highest capacity, and 30 minutes later there were additional mortalities with the same characteristics as the others. He said on May 1, 2019, crews took the juvenile bypass system offline for a brief 40-minute outage. He said the spill water level in R11 was decreased enough to physically see the plug hole, the plug was installed, and the system was returned to service. He said initially after testing, there were a few more mortalities, and on May 3, 2019, there were zero mortalities.

Keller said ultimately, the mortalities were attributed to the drain hole in R11. He said with the plug removed and at certain operational heights, the increased velocity through the area caused fish to slip through the hole or stack up against the hole resulting in mortalities. He said May 1, 2019, was the highest mortality day with 13 mortalities out of 143 steelhead collected. He explained that the drain hole was installed to previously help dewater the area, but a larger dewater pump has since been installed so the drain hole is no longer needed. He said during the next outage crews will modify the drain hole to ensure the plug will not be removed, and the appropriate protocols will be updated to not remove the plug moving forward.

Kirk Truscott asked what proportion of emigrants arriving at Rock Island Dam are subject to the bypass? Keller said to the best of his knowledge it varies but maybe around 2.5% or less. He said the collection efficiency of that system is low.

VI. HCP Administration

A. YN HCP Coordinating Committees Alternate Representative – Brandon Rogers (John Ferguson)

John Ferguson said Bob Rose retired last Friday, May 24, 2019, and Brandon Rogers is Rose's replacement as the YN HCP Coordinating Committees Alternate Representative.

B. Douglas PUD Support Staff – Amber Nealy (John Ferguson)

John Ferguson said Mary Mayo is retiring this Friday, May 31, 2019, and Amber Nealy will be replacing Mayo as Douglas PUD support staff. Tom Kahler said Nealy has been shadowing Mayo for a few weeks, which has been fortunate because Mayo does so much for Douglas PUD Natural Resources Department (NRD). Kahler said Mayo helps with all filings for the Federal Energy Regulatory Commission by the NRD, she conducts a lot of the technical editing for NRD documents, and she manages NRD postings to multiple websites, among other things. Kahler said he believes Nealy will do a good job.

C. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on June 25, 2019, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

John Ferguson said Kristi Geris will be out-of-country June 15 to July 5, 2019, and Larissa Rohrbach (HCP Hatchery Committees support staff) will be managing emails and attending the HCP Coordinating Committees meeting on June 25, 2019. Ferguson said Geris will have Rohrbach's contact information in her out-of-office message as a reminder to distribute emails to Rohrbach during this time.

The July 23 and August 27, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

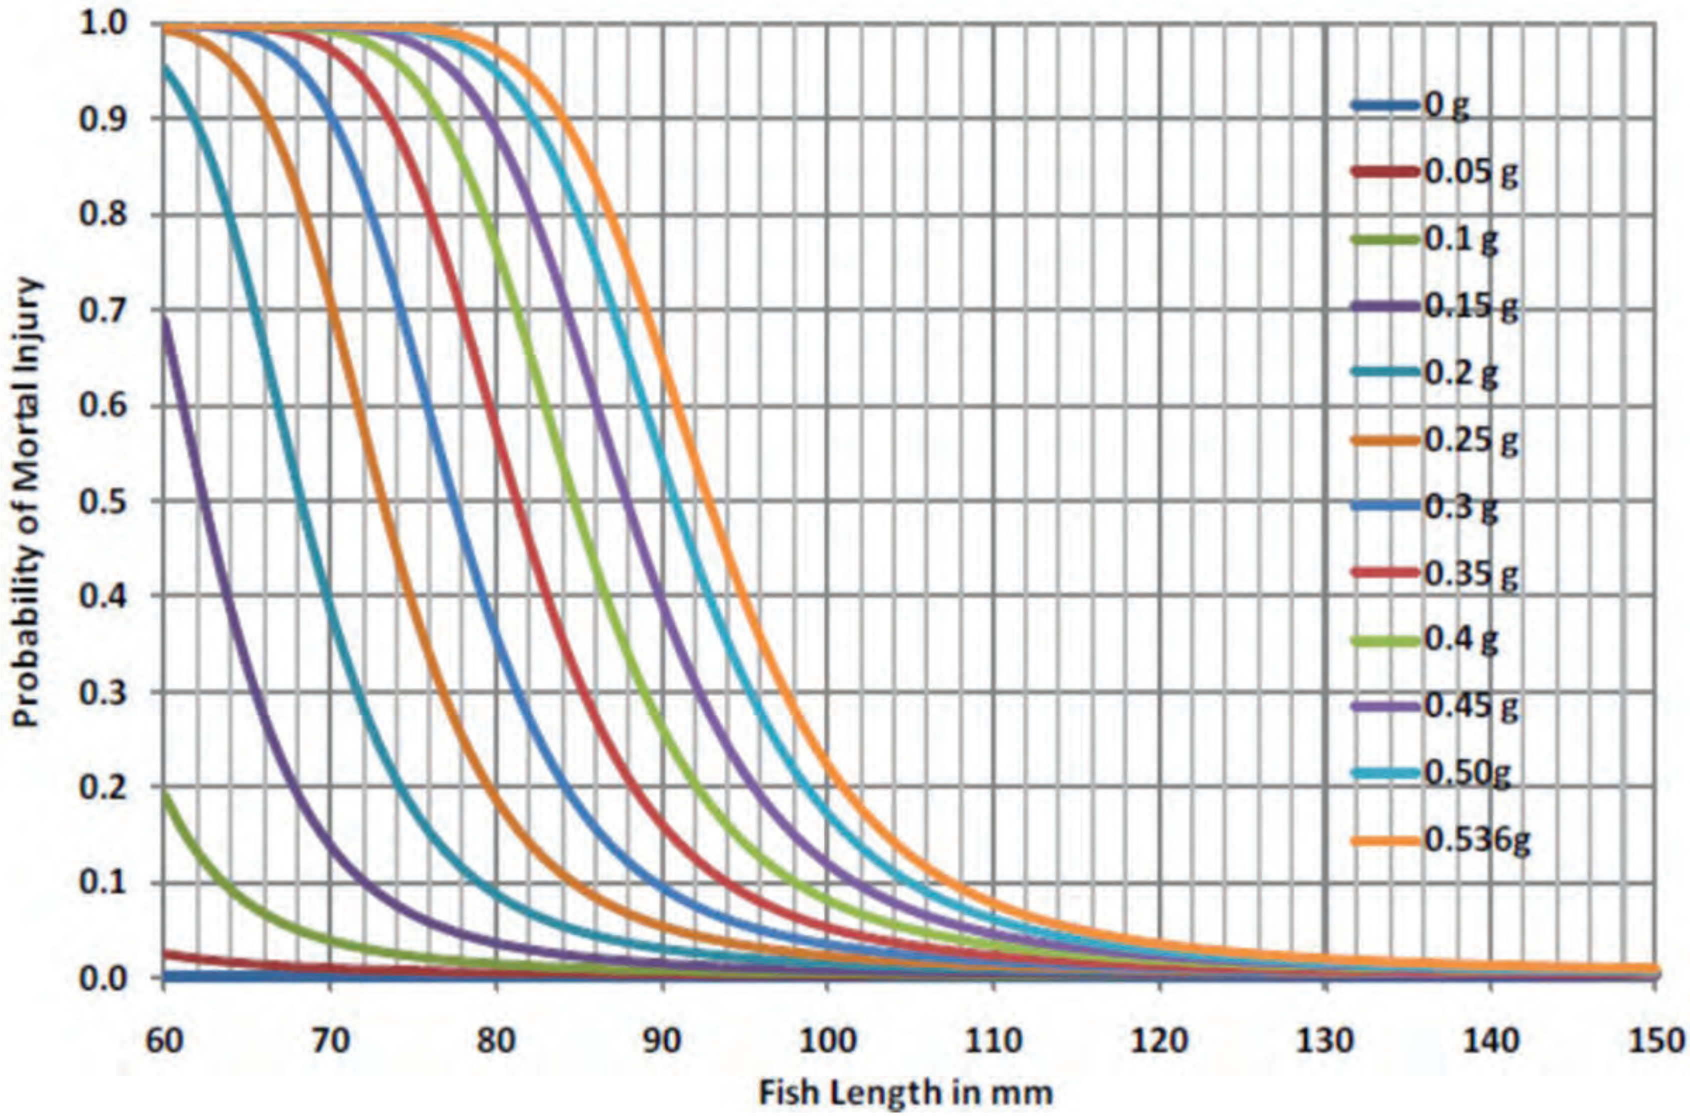
Fish Mortal Injury Index Given Various Transmitter Weights, Under Pressure Changes Simulating Turbine Passage Events



Carlson, T. J., and M. J. Myjak. 2010. Juvenile Salmon Acoustic Telemetry System transmitter downsize assessment. PNNL-19366.

Conclusions

- Subyearling Chinook are abundant and available to beach seining from early-May through mid-July, but difficult to capture by mid-July
- Nearly all subyearlings are too small to PIT tag in May, and nearly all are large enough to tag by the end of July—if you can still catch them!
- Seining captures Chinook <40 mm even into late June, and <45 mm even the third week of July
- The mean size of subs passing Wells Dam exceeds 100 mm by late June, increasing to 130 mm by the third week of August
- The mean size of subs in beach-seine catches is relatively stable from mid-June to late-July, between 70-80 mm
- Beach seining sampled the smaller half of the subyearling size range available from late-May through August
- Subyearlings exhibit a continuum of migration timing, with passage at downstream projects occurring from spring until at least termination of bypass operations in mid-November—few detected as yearlings

Conclusions Continued

- Generally, larger fish had faster and less variable mean travel times to Rocky Reach than smaller fish, over all three years
- We can lump subyearlings into two categories of emigration behavior:
  i. relatively rapidly emigrating fish (travel time to RRJ of 20 days or less) encompassing the full size range of detected fish; and,
  ii. rearing fish comprising the smaller two-thirds of detected fish
- The distinction between these two classes varies between years and within sampling periods in each year, with generally more residents in early tag groups, and more rapid emigrants in late tag groups
- Larger fish had a much greater detection probability at downstream dams than smaller fish
- For study fish that returned as adults, larger individuals at tagging were more likely to return, indicating that greater survival for larger juveniles was the likely basis for their greater detection probability

Conclusions Continued

- The two emigration categories were equally represented in returning adults; thus, neither strategy provided a survival advantage
- We could not identify a size threshold that distinguished active migrants from rearing individuals
- The length of residence time in Wells Reservoir prior to recapture was a good indicator of the length of travel time to RRJ after re-release
- Fish exhibited short-term post-tagging reductions in growth rate, but this effect was not size-dependent, indicating it was a function of the capture and tagging process rather than of tag burden
- We were unable to PIT tag a representative sample of the run at large because fish were too small, and we couldn't catch the largest fish
- At least 16% of PIT-tagged fish emigrate too slowly to utilize the JSATS tag (battery life), and 95% are too small for that tag
- The battery life of the ELAT is presently insufficient for most study fish, and the ELAT is too large for the fish we couldn't PIT tag.

Conclusions Continued

- A traditional study of this population would violate several assumptions of the single- and paired-release study model:
  1. Can't tag a representative sample (many fish too small)
  2. Even the PIT tag disproportionately affects survival probability in small individuals
  3. Not all individuals have the same probability of survival to the end of the reach
  4. Treatment and control groups would experience unequal river and passage conditions in common reaches
- The ELAT currently under development by PNNL holds promise…
- Even if the ELAT battery life improves to match that of the current JSATS, the residence time of 16% of our tagged study fish would exceed that, we still couldn't tag a representative sample of the population, and the mathematical obstacles posed by highly variable and unpredictable emigration/residency behavior have no solution.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: July 24, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Larissa Rohrbach and Kristi Geris

Re: Final Minutes of the June 25, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, June 25, 2019, from 10:00 a.m. to 11:45 a.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine the following: 1) whether the index samples collected represent overall passage trends based on passive integrated transponder (PIT)-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item I-C). *(Note: Keller provided the review of subyearling sampled at RRJSF by email following the meeting on June 25, 2019, as distributed to the HCP Coordinating Committees by Larissa Rohrbach that same day.)*
- Kirk Truscott will contact Lance Keller to further discuss options to increase attraction flow through the cul-de-sac area in the Rocky Reach Dam forebay (near Turbine Units C1, C2, and C3) while Turbine Units C1 and C3 are offline for maintenance (Item I-C).
- Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item I-C).
- Douglas PUD will review available PIT-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item I-C).
- The following action items pertain to the Decision Item whether to approve Douglas PUD's request not to tag with coded wire tags (CWTs) the component of brood year (BY) 2018 summer Chinook salmon raised at Wells Hatchery that will be used for the 2020 Survival Verification Study (2020 Survival Study) because they will be tagged with PIT-tags and

adipose clipped (Item II-A) (*Note: This Decision Item will be brought forward to the July 23, 2019 meeting agenda*):

- Tom Kahler will inform the HCP Coordinating Committees of the planned dates in July when CWT tagging will occur. *(Note: Kahler stated via email on June 26, 2019, that CWT tagging will occur in August, as distributed by Larissa Rohrbach the following day.)*
- Tom Kahler will respond to Keely Murdoch's initial questions about the effects of a decision not to tag with CWTs the 2020 Survival Study fish on the following:
  - Monitoring and evaluation studies
  - Estimates of smolt-to-adult ratios (SARs)
  - The collection of harvest information
- Chad Jackson will determine whether there are concerns associated with not coded wire tagging the study fish from an ocean harvest standpoint.
- Larissa Rohrbach will distribute draft meeting minutes from this agenda item to Kirk Truscott and Scott Carlon following the meeting for their immediate consideration. *(Note: Rohrbach emailed a draft of the relevant minutes on June 26, 2019, to Truscott and Carlon, Cc Tom Kahler, John Ferguson, and Kristi Geris.)*
- HCP Coordinating Committees representatives will email their own or their Hatchery Committees representative's comments and questions to Larissa Rohrbach for distribution by next Wednesday July 3, 2019. *(Note: Per Tom Kahler's email on June 26, 2019, a CWT tagging date in August allows the issue to be brought to the HCP Hatchery Committees in the regular monthly meeting on July 17, 2019.)*
- The HCP Coordinating Committees will vote on whether to approve Douglas PUD's request via email or at the next meeting depending on when a decision is needed for CWT tagging operations. *(Note: Tom Kahler stated via email on June 26, 2019, that CWT tagging will occur in August, as distributed by Larissa Rohrbach the following day.)*

- Lance Keller will provide an update by email on the performance of the new Rocky Reach Dam C3 Unit Chesterton seals by Friday, June 28, 2019 (Item III-A).
- Larissa Rohrbach will distribute by email the acoustic tag specifications sheets shared by Lance Keller following today's meeting (Item IV-A). *(Note: Keller provided the specifications sheets by email following the meeting on June 25, 2019, as distributed to the HCP Coordinating Committees by Rohrbach that same day.)*
- Lance Keller will provide additional information on the change in ATS Inc. acoustic tag weights with different battery types (Item IV-A).
- The HCP Coordinating Committees meeting on July 23, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item V-A).

Decision Summary

- There were no HCP Decision Items approved during today's meeting.

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- The draft *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019, and is available for a 60-day review with edits and comments due to Tom Kahler by Tuesday, July 23, 2019 (Item I-A).

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. No additions or changes were requested.

Kirk Truscott was unable to attend today's meeting and has asked for additional time to consider the decision item "2020 Survival Verification Study – Coded Wire Tags." Note that after discussion in the meeting, the members determined that additional time was needed to understand implications of the decision, so the vote was delayed (see summary of Item II-A).

Ferguson reminded the HCP Coordinating Committees that comments on the *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* are due to Tom Kahler by July 23, 2019.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft May 28, 2019 meeting minutes. Larissa Rohrbach reviewed one comment and incorporated all comments and revisions received from members of the Committees into the revised minutes. HCP Coordinating Committees members present approved the May 28, 2019 meeting minutes, as revised. Jim Craig was absent from the May 28 meeting, so he abstained from voting to approve the minutes. Scott Carlon provided his vote to approve the minutes by email to Rohrbach and John Ferguson on May 17, 2019.

Ferguson provided a status update on the 2019 Columbia River sockeye return. He said this information pertains to a potential desire to revisit the decision made by the Wells HCP Coordinating Committee on May 28,2019, to approve the Columbia River Inter-Tribal Fish Commission's annual request to tag sockeye salmon at Wells Dam in 2019, with the caveat that approval of the tagging will be reviewed again if low flow and warm water migration conditions develop. Ferguson said the 10-year average through June 23 is 117,556; this year's count as of June 23, 2019, is 22,894. Ferguson said sockeye abundance could be low this year (approximately one-fifth of the 10-year average) or could be late due to river conditions.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on May 28, 2019, and follow-up discussions, were as follows. *(Note: Italicized text corresponds to agenda items from the meeting on May 28, 2019):*

- *Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine the following: 1) whether the index samples collected represent overall passage trends based on passive integrated transponder (PIT)-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item II-C).*
  Keller provided the results of his analysis via email following the meeting, as distributed to the HCP Coordinating Committees by Larissa Rohrbach that same day. Keller said the fish count trends are similar between the subyearling Chinook salmon index sample counts at the RRJSF (bypass) and counts of PIT-tagged subyearling Chinook salmon detected at the Rocky Reach Dam Juvenile Surface Collector (RRJ) site. Keller said that the subyearling count at the bypass begins 3 days earlier than at the RRJ. He said more fish passage occurred at night, which aligns with observations made at other sites. He said the question is whether sampling is occurring at the right time. Keller said that he posed the question to fish passage statistician Dr. John Skalski who provided the expert opinion that as long as sampling is carried out at the same time of day and same days of the year every year, the obligation to observe fish presence or absence according to HCP obligations has been met.
- *Kirk Truscott will contact Lance Keller to further discuss options to increase attraction flow through the cul-de-sac area in the Rocky Reach Dam forebay (near Turbine Units C1, C2, and C3) while Turbine Units C1 and C3 are offline for maintenance (Item II-C).*
  This action item will be carried forward.

- *Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item II-C).*
  This action item will be discussed during today's meeting and will also be carried forward.
- *Anchor QEA, LLC, will contact Jim Craig to obtain U.S. Fish and Wildlife Service (USFWS) approval of the updated HCP Hatchery Committees and Priest Rapids Coordinating Committee (PRCC) Hatchery Subcommittee email distribution lists (Item III-A).*
  Kristi Geris emailed Craig with this request following the meeting on May 28, 2019, and Craig provided USFWS's approval of the lists via email on May 29, 2019, as distributed to the HCP Coordinating Committees by Geris that same day.
- *The HCP Coordinating Committees will begin discussing the necessity and significance of the data behind the Columbia River Inter-Tribal Fish Commission's (CRITFC's) annual request to tag sockeye salmon at Wells Dam during the HCP Coordinating Committees meeting in December 2019 (Item IV-A).*
  Kristi Geris added this to the agenda for December 2019.
- *Douglas PUD will review available PIT-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item IV-B).*
  Tom Kahler said a memorandum is currently being drafted and he may be able to present findings in July. This action item will be carried forward.

II. Douglas PUD

A. DECISION: 2020 Survival Verification Study – Coded Wire Tags (Tom Kahler)

Tom Kahler sent information supporting the request for a decision via email, as distributed by Kristi Geris on June 14, 2019. The email stated the following:

"In 2009, the HCP Parties approved a request by Douglas PUD to not coded wire tag study fish for the 2010 Survival Verification Study because 100 percent of those fish would be PIT tagged and ad-clipped. Douglas PUD made that request to not CWT study fish to avoid any negative cumulative effects of multiple tags/marks on their survival. As we near the date for ad-clipping and CWT tagging for the BY 2018 summer Chinook yearlings at Wells Hatchery, Douglas PUD again requests to not CWT the component of the Wells yearling summer Chinook that will serve as study fish for the 2020 Survival Verification Study.

Specifically, with the approval of the Wells Coordinating Committee, Douglas PUD would not CWT 110,000 of the 320,000 (release target) yearling summer Chinook from BY 2018, and instead, those

110,000 fish not tagged with CWTs would be PIT tagged. Those 110,000 fish would be ad-clipped this summer (when the remainder of the BY 2018 yearlings are CWT'd and ad-clipped), then PIT tagged in November. The 110,000 number of PIT-tagged fish is a conservative tagging rate to ensure the availability of at least 100,000 PIT-tagged study fish for the study in April and May 2020, accounting for the in-hatchery mortality rate of PIT-tagged study fish between tagging and release in 2010."

Kahler said that in preparations for the previous 2010 summer Chinook Survival Verification Study (2010 Survival Study), a decision was made not to tag those study fish with CWTs in addition to the PIT tags used for the 2010 Survival Study. Kahler said Douglas PUD had not asked for a similar change to the CWT tagging approach for Wells Hatchery summer Chinook salmon when developing this 2020 study. He said that when working through the bioprogramming issues, they realized in the 2010 Survival Study that Douglas PUD had elected not to tag study fish with CWTs to minimize handling stress and effects of multiple tags. Douglas PUD decided to bring this proposed change to the Wells HCP Coordinating Committee this June as a decision item because CWT tagging would need to occur in July.

Douglas PUD proposes that out of 320,000 Wells Hatchery program yearling summer Chinook salmon that normally receive a CWT and are adipose fin-clipped, the 110,000 designated as 2020 Survival Study fish would be PIT tagged and adipose fin-clipped but would not receive a CWT. Fish would still be available for harvest because of the adipose fin clip.

Keely Murdoch had questions about the proposed change to tagging. Murdoch asked if the fish designated for the 2020 Survival Study would be part of the actual hatchery production or in addition to the normal production. Kahler responded that they would be part of the normal Wells Hatchery production but that in 2010 the Survival Study fish were in addition to the normal hatchery production. Kahler said this is an important difference between the decision made for the 2010 Survival Study and the proposal for the 2020 Survival Study. Murdoch asked if there are any hatchery monitoring and evaluation programs that could be compromised by the use and interrogation of PIT tags instead of CWTs. She asked if SAR estimations that depend on CWT counts could be compromised, noting that in her observation SARs estimated using CWTs differ from SAR estimates made with PIT tags detections due to differences in redetection efficiency. Murdoch also asked if there is any place where these fish would normally be interrogated for CWTs but not for PIT tags, for instance in creel surveys, and if so, would some redetections be miscounted, or harvest information missed? Jim Craig said the USFWS does scan for PIT tags during carcass surveys. Andrew Gingerich asked if Chad Jackson knew whether there are any areas where CWTs are normally interrogated, but PIT tags are not. Jackson said the one concern may be whether the reduction in coded wire tagged fish released would affect ocean surveys or ocean harvest data collection. John Ferguson asked if SARs are calculated using CWT counts. Murdock said yes, CWTs are collected in spawning surveys and broodstock collection. Kahler said for Wells Hatchery summer yearling Chinook salmon, CWTs are the only source of data for calculating SARs except for the PIT tags used in the 2010 study.

Craig asked if this proposal has been brought to the HCP Hatchery Committees. Kahler said no because the Hatchery Committees did not meet this month. Kahler said this topic was discussed in the HCP Hatchery Committees in 2009 for the previous 2010 Survival Study where more time was available to discuss the tagging prior to making a decision. Kahler read from the May 2009 HCP Hatchery Committees minutes to review the approach taken in 2010. Kahler said the same questions came up but that the proposal was approved after discussion.

Ferguson said the proposal to mark Wells Hatchery program fish with a PIT tag instead of a CWT for the 2020 Survival Study is different from the approach used to rear and tag additional fish for 2010 Survival Study. Ferguson said there are questions that require further consideration and the consensus is that the Wells HCP Coordinating Committee is not prepared to vote on the decision in today's meeting.

The following action items were outlined to further the discussion via email, which should lead to a decision prior to CWT tagging operations at Wells Hatchery *(Note: This Decision Item will be brought forward to the July 23, 2019 meeting agenda)*:

- Kahler will inform the HCP Coordinating Committees of the planned dates in July when CWT tagging will occur. *(Note: Kahler stated via email on June 26, 2019, that CWT tagging will occur in August, as distributed by Larissa Rohrbach the following day.)*
- Kahler will respond to Keely Murdoch's initial questions about the effects of a decision not to tag with CWTs the 2020 Survival Study fish on the following:
  - Monitoring and evaluation studies
  - Estimates of SARs
  - The collection of harvest information
- Jackson will determine whether there are concerns associated with not coded wire tagging the study fish from an ocean harvest standpoint.
- Rohrbach will distribute draft meeting minutes from this agenda item to Kirk Truscott and Scott Carlon following the meeting for their immediate consideration. *(Note: Rohrbach emailed a draft of the relevant minutes on June 26, 2019, to Truscott and Carlon, Cc Kahler, Ferguson and Geris.)*
- HCP Coordinating Committees representatives will email their own or their Hatchery Committees representative's comments and questions to Rohrbach for distribution by next Wednesday July 3, 2019. *(Note: Per Kahler's email on June 26, 2019, a CWT tagging date in August allows the issue to be brought to the HCP Hatchery Committees in the regular monthly meeting on July 17, 2019.)*

- The HCP Coordinating Committees will vote on whether to approve Douglas PUD's request via email or at the next meeting depending on when a decision is needed for CWT tagging operations. *(Note: Kahler stated via email on June 26, 2019, that CWT tagging will occur in August, as distributed by Rohrbach the following day.)*

B. Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report (Tom Kahler)

The draft *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019, and is available for a 60-day review with edits and comments due to Tom Kahler by Tuesday, July 23, 2019.

Kahler asked whether representatives had any questions regarding the content of the report. Keely Murdoch asked for clarification on differences in migration behavior between Snake River subyearling Chinook salmon and Upper Columbia River subyearling Chinook salmon, information that was initially provided in the associated presentation that was given in the May 28, 2019 meeting.

Kahler said that in the Snake River, the Chinook salmon are fall-run Chinook salmon that are already in the migrant stage and are larger by the time the juveniles migrate through the lower Snake River hydroprojects as subyearlings. In contrast, Chinook salmon from the Okanogan and Methow rivers or Rocky Reach tributaries are passing through reservoirs at a very small size; they are essentially swim-up fry. To give an idea of the size of the subyearlings in the Snake River, 99% of the size distribution can be tagged with a Juvenile Salmon Acoustic Technology System (JSATS) tag to evaluate passage through the Snake River projects, even though the minimum fish length for tagging is 95 mm (fork length).

John Ferguson asked what the survival rate requirement is for the Snake River hydroprojects. Kahler said they don't have a "project" (tailrace-to-tailrace) survival rate requirement for individual hydroprojects like they do for the mid-Columbia PUD projects. Instead, they have a dam-passage (forebay-to-tailrace) survival standard of 96%. It was noted that the survival standard is for yearlings, and the survival standard for subyearlings in the FCRPS is lower: 93% dam-passage survival.

Murdoch asked for confirmation that the mid-Columbia HCPs do not have that same requirement, and Kahler answered that is correct. Kahler said the main point to emphasize is that in the Upper and Mid-Columbia, biologists are trying to study fry, whereas in the Snake River they are studying the migrant life stage.

No other questions about the draft report were asked in the meeting. Ferguson concluded the agenda item by reminding the HCP Coordinating Committees that the 60-day review period is ongoing and ends on July 23, 2019.

III. Chelan PUD

A. Rocky Reach Dam Turbine Unit C1 and C3 Update (Lance Keller)

Lance Keller said work continues on Turbine Unit C1. He said the unit has been disassembled to the point that the trunnion bushings are revealed. He said the project is still on the same timeline for completion as previously discussed. The disassembly will allow for the replacement of the trunnion seals to avoid the problem with seals that has occurred with Turbine Unit C3.

Keller said new engineered Chesterton seals for Turbine Unit C3 are on site at Rocky Reach Dam. He said the seals have been engineered for the site and are undergoing testing to determine if they are performing as designed. He said testing began last week. Keller said he would provide an update on performance of the Chesterton seals by end of week. Keller said Chelan PUD will continue to explore the blade block option for Turbine Unit C3, as well. He said there will be engineers from Italy on site next week. He said that even if the seals work, hydraulically locking the blades may be pursued as an additional control option.

Keller said there are additional seals en route from Voith (a hydroproject manufacturer) for Turbine Unit C3 that could also be installed and tested.

Keller said that at the end of September or early October, Turbine Unit C9 will also be coming on line. Keller said that Chelan PUD has never conducted commissioning of two turbine units simultaneously. Keller said because of this conflict he will inquire whether the schedule for bringing C1 online may shift earlier. He said either way, the return of Turbine Unit C1 to service will occur outside the 2019 juvenile passage season.

B. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said Chelan PUD continues to modernize Turbine Unit B4. Keller said some parts have caused delayed (the rotor poles and hydraulic power unit) but Chelan PUD does not expect the schedule for project completion to be delayed. Keller said Turbine Unit B4 is scheduled to come online in the fourth quarter of 2019.

Keller said the operating ring that sits on top of the wicket gates associated with Turbine Unit B4 will be repaired and retained to avoid schedule delays. The rings on the other units will be modernized and replaced first. There is no critical need to change the operating ring on B4 immediately so it will be modernized after the other units. The head cover unit for B4 will also be replaced.

IV. Joint HCP Coordinating Committees and PRCC

A. Subyearling Chinook Salmon Studies (All)

John Ferguson welcomed Peter Graf (Grant PUD) who joined the discussion of approaches to subyearling Chinook salmon studies.

Lance Keller reviewed the availability of current acoustic tag technology to illustrate improvements that have been made since the last review in 2016. Keller distributed specifications sheets for current tag types and made comparisons to tags that were discussed in 2016 (acoustic tag specifications sheets were emailed by Keller and distributed by Larissa Rohrbach following the meeting, see Attachment B).

JSATS AMT by Lotek

In 2016 the JSATS AMT by Lotek was the smallest tag offered by the company. It weighed 0.28 gram in air and had a 25-day battery life using a 5-second ping rate (model number L-AMT-1.416). The specific information for this tag is still current, as the tag has not changed since 2016.

Chelan PUD uses a 3-second ping rate for higher resolution in the immediate proximity of their hydroprojects. A higher ping rate provides more detections and higher accuracy in the location of the last detection. Andrew Gingrich said there is better detection probability, but shorter tag life associated with the higher ping rate. Keller said yes. Ferguson asked what tag lifespan is needed. Keller said it is ideal to have a tag that has adequate tag life to ensure detection throughout the project area, as well as the downstream detection arrays. Keller said this is easily achieved with spring migrants (that move downstream rapidly and are sure to out-migrate), but not ideal for use in subyearlings that could possibly residualize in the reservoirs. Gingerich said the fish does not even have to residualize, it just has to take 15-20 days to move downstream, which it looks like many subyearlings do.

Keely Murdoch said if you were catching run-of-river fish in the Juvenile Bypass System at Rocky Reach Dam you would have a higher propensity to capture actively migrating fish of an appropriate size. Murdoch asked whether there are any subyearling hatchery releases upstream of Rocky Reach Dam. Keller said yes, from Chief Joseph Hatchery and Wells Fish Hatchery. Keller said in late May you see a pulse of hatchery-origin subyearling Chinook salmon that causes Chelan PUD to initiate the spill program, while the wild subyearlings begin outmigrating later into June.

Murdoch asked whether there is any PIT-tag data that could be used to observe migration rate. Tom Kahler said they have been PIT tagging fish at Wells Fish Hatchery to support the Comparative Survival Study fish. Keller said using PIT-tagged hatchery fish would lead to an assumption that the migration rate of the hatchery fish represents the whole population. Murdoch said there are similar assumptions made in other cases. Keller said Chelan PUD tags fish that are run-of-river; as long as size and health criteria are met, fish are tagged and regardless of their origin. Keller said it is obvious when hatchery subyearlings arrive in May and wild-origin summer fish arrive later. Keller said the timing of the wild fish is not very predictable and depends on environmental conditions. Murdoch asked if there are any studies that are tagging wild fish. Kahler said there are some in the Methow and Okanogan rivers, and the Colville Confederated Tribes continue tagging in Wells Reservoir. Graf said some fish are tagged in the Entiat River screw trap. Graf said that for the previous subyearling summit held in 2016, he analyzed PIT-tag data coming from the Entiat River. Graf said some subyearlings come out of the Entiat River and go through Rocky Reach Dam quickly, then have a long delay downstream of Rocky Reach Dam; some go straight to McNary Dam and some take a year to get to McNary Dam. Graf said Tom Desgroseillier (USFWS) may have carried on that work. Kahler emailed presentations from the June 2016 subyearling workshop by Graf (*Comparing the Migration Patterns of Yearling Spring Chinook and Subyearling Summer Chinook Salmon Through the Mainstem Columbia River Using Available PIT-Tag Data*) and Desgroseillier (*Life-History of Subyearling Chinook Migrants from the Entiat River*), as distributed by Rohrbach that same day.

Vemco-HTI Tag

Keller said the next tag to discuss is the Vemco-HTI tag. He noted that Vemco and HTI have merged and that HTI's parent company Amirix has been purchased by InnovaSea, a company focused on aquaculture. Keller said the 307-kilohertz tag is 0.3 gram in air, can be detected on Vemco or HTI receiver systems, and the battery life is 45 to 90 days (it is closer to 45 days with a 3-second ping rate). Keller said the finished product will be more complete (requiring less steps for the user) than in the past. Keller said the size is slightly smaller than in the past (Vemco was previously using a 0.5- to 0.65-gram tag in 2011, which was still the best available tag in 2016). Graf asked if the batteries are different or if they are all from technology developed at Pacific Northwest National Laboratory (PNNL). Gingerich said PNNL will do the research and development of tags, and then after a year or so, hand off the specifications to the manufacturers who then mass produce the tags. Ferguson said the batteries would likely be manufactured by a battery manufacturer.

ATS JSATS SS300 Acoustic Micro Transmitter

Keller introduced the next tag, the ATS JSATS SS300 acoustic micro transmitter. Keller said it has multiple ping rates; the battery lasts 23 days using the 3-second ping rate. More battery life requires the larger tag size and additional batteries. In 2016 the tag weight was 0.34 gram in air, now it is 0.3 gram, and the battery life is the same. Gingerich said this is the tag that has been used by U.S. Army Corps of Engineers exclusively on lower Columbia River studies.

Ferguson asked what the body burden recommendations are, approximately 5%? Keller said yes and noted a recent PNNL presentation that showed injury from barotrauma associated with passing through hydroelectric turbines increased with an increase in tag size/tag burden. Keller noted that there is a broad range in body size for subyearlings. Gingerich said for reference, a 0.3-gram tag is similar in weight to 3 PIT tags.

Murdoch asked how much heavier a tag would be with additional batteries. Keller said it is probably quite a bit bigger since the battery is a large proportion of the tag. Murdoch asked if tag shape has an effect on barotrauma. Keller said no, not to his knowledge. Ferguson said not barotrauma, but tag shape affects incision size and extrusion rate. Gingerich said barotrauma had to do with how much air has to be brought into the swim bladder to compensate for the tag burden. Kahler said the observations with barotrauma were tag extrusion, viscera extrusion, and swim bladder rupture. Ferguson said this has to do with the air bladder being larger already and putting pressure on viscera when the air in the bladder expands as the fish passes through low pressure areas below turbine unit blades.

ATS SS400 Acoustic Transmitter

Keller said the ATS SS400 acoustic transmitter is the "injectable tag" developed by PNNL. Keller said it does require a large needle compared to PIT tags, so the standard practice is still to create an incision. Gingerich asked if there were sutures. Kahler said no sutures are necessary. Keller said a 3-second ping rate would have a 48-day tag life, and it weighs 0.216 gram in air. Keller, Graf, and Kahler saw the tag in person and said it is obviously bulkier than a PIT tag. Keller said that even with a 48-day tag life, there is still the issue with non-migrants influencing passage statistics. Graf said ATS Inc. is still recommending not tagging fish less than 95 millimeters (mm) in length, which is no different than the ATS SS300. Keller said yes, this is not an improvement regarding being able to tag smaller fish, but there is not a need for sutures and there is less tag burden, which is a major improvement to the tagging process. Keller said that with high water temperatures there is always increased stress and disease problems with holding and tagging fish. Murdoch asked for further information on tag weight with additional batteries from ATS Inc. Keller said he would ask ATS Inc. for that information.

Eel/Lamprey Acoustic Tag (ELAT)

Ferguson asked about the Eel/Lamprey Acoustic Tag (ELAT). Keller said they did see the ELAT in-person as well, but it is not commercially available at this time. Keller has reached out to Ryan Harnish for more information. Kahler said it has a 40-day life with a 5-second ping rate. Gingerich roughly estimated that the tag burden would be 2% to 3% for a 95-mm-size fish.

Ferguson asked for any additional questions; no others were posed in the meeting. Ferguson asked what the next steps should be for conveying information in preparation for survival studies. Keller suggested a presentation be given in July by Dr. John Skalski to understand whether there is a statistical model that can be created from the best available data. This allows the Rock Island and

Rocky Reach HCP Coordinating Committees time to draft a statement of agreement (SOA) in August (the current SOA that maintains Rock Island and Rocky Reach subyearling Chinook salmon in Phase III [Additional Juvenile Studies] status expires in late September).

B. HCP Tributary Committees Dispute Update (All)

John Ferguson said the formal dispute has been retracted by Steve Parker (Yakama Nation) at Ferguson's request, allowing the Policy Committee time to convene a meeting to discuss the topic informally. Ferguson asked Keely Murdoch to thank Steve Parker for withdrawing the formal dispute. He said the Policy Committee discussion of the Tributary Committees' issues will be on July 9 in the Chelan PUD offices. Tom Kahler will represent Douglas PUD as the Policy Committee representative. Richie Graves (National Marine Fisheries Service) will attend by phone. Ferguson will issue a simple agenda later this week for the meeting. Ferguson said the idea is to have a straightforward and open discussion of the issues.

Ferguson asked if there were any questions; Murdoch asked if a step to bring the issue to the HCP Coordinating Committees was skipped because of time. Ferguson said that retracting the formal dispute allows the Policy Committee to take the time to set a meeting date when all parties can attend and that is not being driven by the schedule established by the HCP. He indicated the HCP Coordinating Committees have discussed the dispute issues and made it clear they would be unable to reach a consensus position and would in all likelihood pass the dispute along to the Policy Committee. He said retracting the formal dispute allowed for all parties to meet in July. He said meeting informally does get to the intent of getting the Policy Committee together to discuss these issues because the Tributary Committee cannot reach a consensus on some funding or land ownership decisions at this time. Ferguson said the Yakama Nation issue paper will be presented as the main agenda item at the Policy Committee meeting. Ferguson said a goal will be to determine whether the Policy Committee can provide guidance to the Tributary Committees on how they should be operating. The Policy Committee may require only one meeting or they may require more. Ferguson said this uncertainty around the time needed requires more flexibility for ongoing discussion and led to the request to retract the formal dispute at this time.

V. HCP Administration

A. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on July 23, 2019, to be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington.

The August 27 and September 24, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

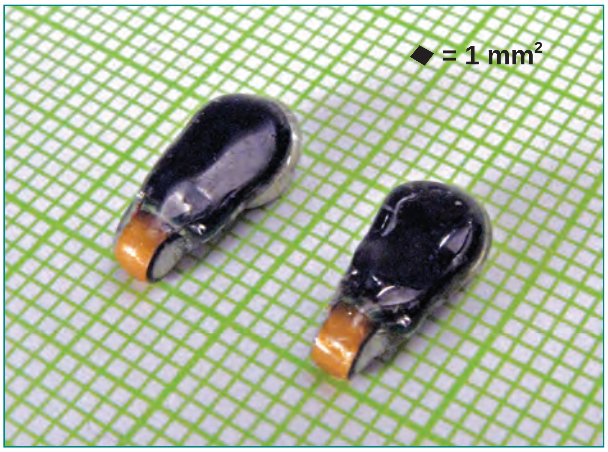
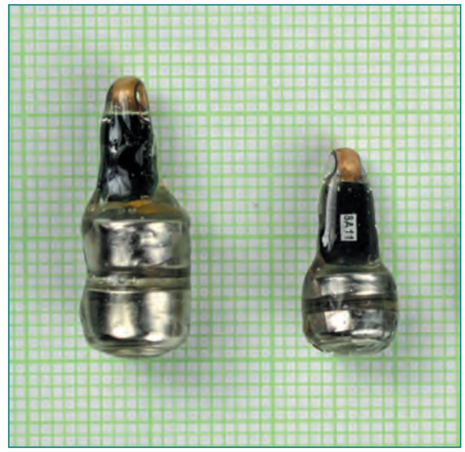
JSATS AMT

Juvenile Salmon Acoustic Telemetry System
Acoustic Micro Transmitter



L-AMT-1.416 *L -AMT-1.421*



L-AMT-8.2 *L -AMT-5.2*

The Lotek JSATS AMT – Juvenile Salmon Acoustic Telemetry System Acoustic Micro Transmitter – was developed to satisfy the research and regulatory requirements for monitoring juvenile salmon in the Columbia River Basin. The transmitter's small size and relatively long operational life permits tracking of sub-yearlings throughout their natural environment while minimizing impact upon them.

The Lotek JSATS AMT transmitter is compatible with JSATS receiving systems and utilizes a Binary Phase-Shift Keying (BPSK) coding system that allows for tens of thousands of unique IDs on a single acoustic frequency. Each transmission consists of an ID and check sum delivered in less than one millisecond thereby minimizing the probability of mis-identification or interference from code collision.

Key Features

- Small size and light weight (0.28g) - suitable for small fish and sub-yearling applications
- Over 65,000 unique Ids - embedded check sum reduces error rate
- Sub-millisecond ID message length provides long life and reduced "code collision" rate
- Used for autonomous monitoring presence/absence
- Used for wireless positioning in 2D via Lotek UMAP positioning system
- Now available as JCART combined acoustic/radio transmitter compatible with SRX (400/600/800/DL) radio receivers and WHS 4000 acoustic receivers

JSATS AMT

Specifications

Lotek JSATS AMT Juvenile Salmon Acoustic Telemetry System Acoustic Micro-Transmitter						
TAG MODEL	Physical Specifications		Calculated Life (days)* (with given transmission period-seconds)			
	Size (mm)	Dry Weight (g)	2s	5s	10s	20s
L- AMT-1.416	10.7 x 5.4 x 3.1	0.28	10	25	48	87
L- AMT-1.421	11.1 x 5.5 x 3.7	0.32	15	38	72	131
L-AMT-5.1 B	5 x 7 x 13	0.6	39	95	180	327
L-AMT-5.2	7 x 7 x 16	1.1	81	189	341	568
L-AMT-8.2	9 x 23	3.5	218	508	914	1522
L-AMT-14-12	14 x 45	8.0	429	1009	1837	3114

** Calculated life represents expected or average life*
Warranty Life is 80% of calculated life
Maximum warranty life is three (3) years
Minimum signal strength is +158 dB (re 1 uP @ 1 meter)
Transmitters that do not meet the warranty life during normal use will be replaced

Product specifications provided herein are subject to change as a result of ongoing product development. Please contact your Lotek sales representative for current specifications.
Product specifications tolerance +/- 5%.

Surface Roughness:	Smooth and devoid of sharp edges or protrusions
Coating:	Parylene-C (25 microns min. thickness) or alternate field proven encapsulation
Biocompatibility:	Biologically inert coating
Shape:	See photographs
Transmitter frequency:	416.7 kHz ± 0.05%
Transmitter power:	Typical source level of +158 dB (re: uPa @ 1 meter)
Pulse Repitition Interval (PRI):	Factory configurable - 1 second minimum / 1 second increments
ID Message encoding:	31-bits, BPSK, with format as follows: 1. 7-bit Barker code (ox72) 2. 16-bit tag ID code (0x0000 – 0xFFFF) 3. 8-bit cyclic redundancy check (CRC), (oxFF)
ID Message length:	744 microseconds
Number of possible tag ID codes:	65,536
On/off switch:	Non-contact acoustic trigger device, i.e. no exposed wires; tags are fully encap-sulated when delivered.
Transmitter label:	Discernable 4-character hex-code representing the 16-bit tag ID code (0xFFFF)

Prior to delivery, 100% of all transmitters are tested for adherence to dimensional and dry weight specifications, acoustic source level, code sequence and transmit interval.

Shipment of AMT:

Transmitters are separated in the shipping box using shock absorbing high density anti-static foam.

V3 307 kHz Coded Transmitters

VEMCO's miniature coded transmitters open up a new world for small fresh and salt water species research

Smaller Fish, More Species

Weighing just 0.3 grams and measuring 15 mm in length, the V3 tag is the smallest of VEMCO's line of miniature coded transmitters. The V3 enables researchers to track and monitor smaller fish and a broader range of species than ever before!

Why a Higher Frequency?

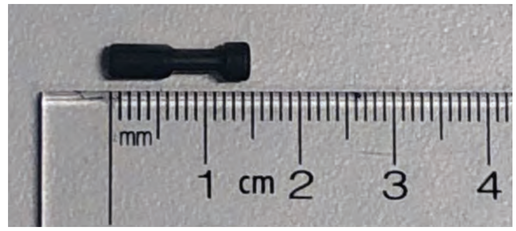
The V3, operating at 307 kHz, is designed to work well in fresh water. This frequency enabled VEMCO to develop a lightweight tag that allows researchers to track a large number of fish in a small space. Researchers can now tag and release many more fish simultaneously due to the detection capabilities of our new tag transmission sytems.

Compatible Receivers

The V3 works with VEMCO's new High Residence HR3 Receiver, as well as HTI 290-Series Receivers and 395 Data Loggers. The HR3 can be deployed remotely, or cabled for real-time detections, and can be programmed to detect either HR or HTI coding schemes, or both schemes alternating.

High Residence (HR)

HR represents a more aggressive transmission system that offers the ability to detect many more tagged animals at once. Each HR ID code is embedded in each short ping transmitted by the tag. This allows the HR3 receiver to detect many IDs in a short period of time.



Benefits of HTI Coding

The HTI coding structure provides researchers with high performance in noisy and reflective environments. Alternating HTI and HR coding schemes provide researchers with interesting study possibilities that previously weren't possible, in a tag designed for very small fish. The HTI coding (i.e. the ability to vary pulse widths and signal types, etc.) in the V3 tag also allows for cross-compatibility with HTI equipment.

HR3 Receiver

The new HR3 receiver is capable of very precise signal timing, which makes the HR3 ideal for anyone interested in accurate spatial 2D/3D positioning with sub-meter resolution. Many tagged animals can be tracked in a short period of or have their movements tracked as they move quickly through acoustic gates (i.e. river survival study). Using a VR100 and VHTx-307 hydrophone, HR3 receivers can be communicated with, to query things such as tilt, pressure (depth), temperature, battery usage, memory used, and detection count.

Advantages of VEMCO's 307 kHz Product Line

- Two transmission systems (HR and HTI) in one tag provides flexibility for study designs and research objectives
- Real time monitoring of HR and HTI tags (HR3s and HTI 290-series receivers)
- HR and HTI transmission systems available in all 307 kHz tag models
- Able to transmit HR, HTI, or both signals alternating

High Residence (HR) **and HTI transmission** systems offer new ways of detecting your tagged animals!

www.vemco.com

Programmable ON/OFF

The V3, as with all VEMCO transmitters, is available with programming options that allow users to take greater advantage of fish behaviour over the life of their tags. In order to control the characteristics of their tags, users have the option of using up to four programming steps to define the tags transmission: Status (ON/OFF), time interval, nominal delay, and transmission type (HR / HTI / Alternating).

This is an example of how V3 tag programming options can be utilized to provide a staged release tag behaviour.

Interval	Status	Time	Power (H)	Nominal Delay (sec)
Step 1	ON	1 hour	H	30
Step 2	OFF	7 days		
Step 3	ON	70 days	H	10

When finished, LOOP back to Step 3.

Step 1: The tag is programmed to start with a nominal delay setting of 30 seconds for a period of 1 day. This allows a researcher to activate a tag and have it transmit for 1 day during the surgical implantation phase of the study.

Step 2: The tag is programmed to turn OFF for a period of 9 days. In order to conserve battery life while the animals recover from surgery, the tags are switched to the OFF status since the location of the animals is known.

Step 3: The tag is programmed to turn ON with a nominal delay setting of 60 seconds for a period of 45 days. This allows a researcher to release and track the animals during a 45 day migration period through a given study area.

Step 4: The tag is programmed to stay ON with a nominal delay setting of 180 seconds for a period of 15 days. This allows a researcher the ability to track the animals for 15 days during what might be a more residency type setting. Note the Loop control setting is set to Step 4 thus keeping the tag in the ON status until the tag reaches its battery end of life.

VEMCO Tag Activator (VTA)

The VTA is a handheld device that enables users to quickly and easily activate 307 kHz transmitters.

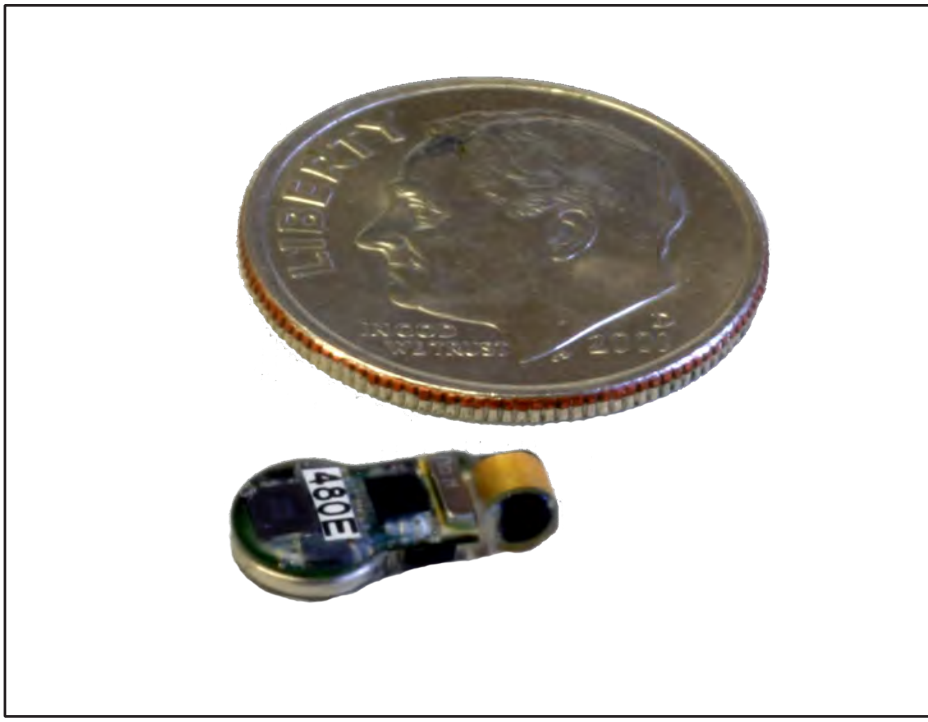
Please consult with VEMCO if you are considering 307 kHz products. We can help you fine tune your study design and programming options!

Attachment B

ATS SS300 Acoustic Micro Transmitter

World's Most Reliable Transmitters and Tracking Systems



The New Third Generation model SS300 Acoustic Tag is Significantly Smaller in Size Without Sacrificing Life or Signal Strength.

The Juvenile Salmonid Acoustic Telemetry System (JSATS) was developed by the Army Corps of Engineers and its partners to study fish behavior in freshwater and marine environments. ATS has been manufacturing large numbers (more than 10,000 tags per year) of acoustic micro transmitters (AMT's) for the JSATS program since 2007. Through our innovative designs, the JSATS transmitter has significantly decreased in size, increased in power output, and become easier to deploy in the field. We've achieved these improvements while still offering another ATS trademark - low cost!

The JSATS system uses a binary phase shift keyed (BPSK) code pulse to achieve a code set of over 65,000 individual ID's. The pulse rate interval (PRI), code ID, and duty cycling (sleep/delayed activation) are user configurable through the use of the highly portable ATS Pinger Dish. The pulse train contains a 7-bit Barker code, 16-bit tag ID code, and 8-bit cyclic redundancy check (CRC). The message is only 744 milliseconds in length, so the short on-time saves power and reduces signal collisions as compared to other standard timing code sets on the market.

ATS manufactures JSATS transmitters using strict process control procedures and part traceability, so you can be assured that you will receive a reliable product.

- **Part of a complete Tracking System includes Tags, Tag Programmer, and Receiving Equipment**
- **Smallest Acoustic Tag Available that meets Life and Output Requirements of the JSATS Program**
- **User Configurable**
- **Model SS300**
  - **Weighs 300 mg**
  - **Size 10.7 x 5.0 x 2.8 mm**

ATS SS300 Acoustic Micro Transmitter

PHYSICAL

SS300

- Size: 10.7 mm long x 5.0 mm wide x 2.8 mm high
- Weight, dry: 300 mg; heavier depending on battery used
- Expected life:

Battery Type	Interval (sec)	Expected run time (days)
337	3	23
	5	37
	10	68
379	3	45
	5	73
	10	136
377	3	79
	5	128
	10	238

GENERAL

- Code set: 65,536 individual BPSK codes
- Frequency: 416.7 kHz ± 0.5%
- Power output, typical: +156 dB re: 1uPa @ 1 meter
- Biocompatible coating: Parylene C, 25 micron thickness
- Pulse rate interval (PRI): Factory or user configurable with Pinger Dish
- On/off: Acoustic coded with Pinger Dish
- Label: 4 place alphanumeric code ID
- Code ID: Factory or user configurable with Pinger Dish
- Duty cycling: Factory or user configurable with Pinger Dish

ATS Pinger Dish III

The ATS Pinger Dish III is designed to be an inexpensive, field-portable unit to activate and deactivate AMT's (acoustic micro-tags). When a tag is activated in the pinger dish, the integrated display shows the tag frequency, code ID, CRC (cyclical redundancy check) and the PRI (pulse rate interval).

The improved model III features a more durable and robust design, making high volume field operations easier and more efficient. Decoding algorithms have been improved, and the programming control signal is now four times stronger than the previous model, making communications between tag and reader highly reliable. Pulse rate interval resolution displayed on the screen has increased from 0.01 to 0.001 seconds, and the LCD display size has increased from 2 lines x 16 characters, to 4 lines x 16 characters.

The dish operates on 12 VDC, and is powered by an included converter that utilizes 120 VAC. Connecting the Pinger Dish III to a PC via a RS232 serial cable allows the PRI, code ID, and duty cycling parameters to be user configurable.

The included Sonic Tag Integrator software may be used on the PC side to control tag activation, and to create a database of activation and tagging activities.

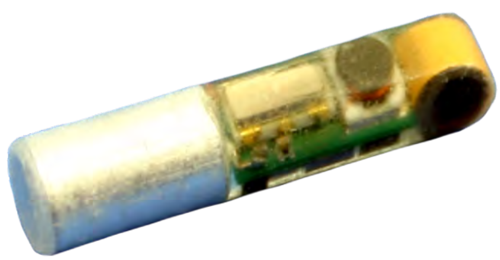
ATS SS400 Acoustic Transmitter

World's Most Reliable Transmitters and Tracking Systems



The New Fourth Generation model SS400 Acoustic Tag allows for easy insertion into the fish, and is JSATS compatible.

The Juvenile Salmonid Acoustic Telemetry System (JSATS) was developed by the Army Corps of Engineers and its partners to study fish behavior in freshwater and marine environments. ATS has been the acoustic micro transmitter (AMT's) supplier for the JSATS program since 2007. The cylindrical form factor used in this design allows you to more quickly insert the tag into the fish, which will save time and expense during fish tagging operations and improve survival.

The JSATS system uses a binary phase shift keyed (BPSK) code pulse to achieve a code set of over 65,000 individual ID's. The pulse rate interval (PRI), code ID, and duty cycling (sleep/delayed activation) are user configurable through the use of the highly portable ATS Pinger Dish. The pulse train contains a 7-bit Barker code, 16-bit tag ID code, and 8-bit cyclic redundancy check (CRC). The message is only 744 milliseconds in length, so the short on-time saves power and reduces signal collisions as compared to other standard timing code sets on the market.

ATS manufactures JSATS transmitters using strict process control procedures and part traceability, so you can be assured that you will receive a reliable product.

- **Part of a complete Tracking System includes Tags, Tag Programmer, and Receiving Equipment**
- **Cylindrical form factor allows tag to be quickly inserted into fishes body cavity**
- **Smallest acoustic tag available that meets life and output requirements of the JSATS Program**
- **User activated and configurable using the portable Pinger Dish**
- **Model SS400**
    - **Weighs 216 mg**
    - **Size 15.0 x 3.38 mm**

ATS Pinger Dish IV

The ATS Pinger Dish IV is designed to be an inexpensive, field-portable unit to activate and deactivate AMT's (acoustic micro-tags). When a tag is activated in the pinger dish, the integrated display shows the tag frequency, code ID, CRC (cyclical redundancy check) and the PRI (pulse rate interval).

The model IV features a durable and robust design, making high volume field operations easy and efficient. With specialized decoding algorithms and a high energy programming control signal, communications between tag and reader are highly reliable. The display uses a large 16 character by 3 line LCD for easy readability.

The dish operates on 12 VDC, and is powered by an included converter that utilizes 120 VAC. Connecting the Pinger Dish IV to a PC via a RS232 serial cable allows the PRI, code ID, temperature, and duty cycling parameters to be user configurable.

The included Sonic Tag Integrator software may be used on the PC side to control tag activation, and to create a database of activation and tagging activities.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: August 28, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the July 23, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, July 23, 2019, from 10:00 a.m. to 1:45 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- HCP Coordinating Committees representatives will prepare technical questions and considerations concerning the feasibility of conducting subyearling Chinook salmon studies with the current information and technology available to date, for discussion with Drs. Rebecca Buchanan and John Skalski (University of Washington [UW], Columbia Basin Research) during the HCP Coordinating Committees meeting on August 27, 2019 (Item I-A).
- Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item II-C).
- Douglas PUD will review available passive integrated transponder (PIT)-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item II-C).
- Kirk Truscott will submit Colville Confederated Tribes (CCT) comments on the draft *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* to Tom Kahler by Friday, July 26, 2019 (Item V-B).
- The HCP Coordinating Committees meeting on August 27, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item VII-A).

Decision Summary

- There were no HCP Decision Items approved during today's meeting.

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- The draft *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019; Douglas PUD will request approval of the report during the HCP Coordinating Committees meeting on August 27, 2019 (Item V-B).

Finalized Documents

- There are no documents that have been recently finalized.

I. Joint HCP Coordinating Committees and PRCC

A. Considerations in the Design and Analysis of Subyearling Chinook Salmon Survival Compliance Studies – 2019 (Rebecca Buchanan)

The presentation titled, *Considerations in the Design and Analysis of Subyearling Chinook Salmon Survival Compliance Studies – 2019* (Attachment B) was distributed to the HCP Coordinating Committees by Kristi Geris on July 20, 2019.

Slides 1 to 2

Dr. Rebecca Buchanan said there have been no significant developments in statistical analyses for estimating reach survival of subyearling Chinook salmon; however, there have been some new developments for estimating at-dam passage survival. Buchanan said this presentation will include a refresher on the requirements and assumptions for a paired release-recapture design, a review of studies, and study recommendations.

Slides 3 to 4

Buchanan said project survival can be estimated using a paired release-recapture design, based on the Cormack-Jolly-Seber (CJS) model, which requires control and treatment releases and a minimum of two downstream detection sites. She said detection arrays need to be placed at the upstream end of one pool and at the downstream end of the next pool. She said arrays in the tailrace of a dam need to be far enough downstream to avoid detecting dead fish in the immediate tailrace (which results in a positive bias) and far enough downstream that fish in both releases have completed expressed short-term handling effects, but not too far that fish in Release 1 (R_1) are exhibiting tagger effects or tag burden effects (negative bias). She said an estimate (S_1) of the probability of survival from R_1 to the first detection site (dashed line labeled P_1 and P_2)[1] and an estimate (S_2) of the

[1] Where P_1 is the probability of tag detection at the first detection site for a fish from R_1, conditional on the tag being present at the detection site (i.e., "detection probability"); and P_2 is the probability of tag detection at the first detection site for a fish from R_2, conditional on the tag being present at the detection site.

probability of survival from Release 2 (R_2) to the first detection site are calculated. She said the last reach parameter estimates the joint probability of: 1) surviving from the first detection site to the second detection site; and 2) being detected on the second detection site, conditional on having survived to the first detection site, for fish from R_1 (λ_1) and R_2 (λ_2). She said the ratio of the estimated survival for one release ($\hat{S}_1$) to the other release ($\hat{S}_2$) equals the estimated project survival ($\hat{S}_{\text{Project}}$). She said if the detection arrays are placed as described, the short-term handling effects for $\hat{S}_1$ and $\hat{S}_2$ should be the same and will cancel out.

John Ferguson asked about additional rules or recommendations for placement of the first and second detection arrays. Buchanan said for each respective tailrace location, one must consider how far dead fish are drifting downstream. She said studies conducted in mainstem rivers place arrays anywhere from 25 to 50 river kilometers (rkm) downstream of the dam. She said, however, the arrays cannot be located too far downstream where fish from R_1 are exhibiting tag burden effects. She said additionally, arrays in the tailrace should be placed far enough downstream where there is complete mixing of fish from the different releases. She said two downstream arrays are the minimum design requirements, but more than two are needed to test the assumptions. She said 8 to 10 arrays are ideal.

Kirk Truscott said it seems placing arrays farther downstream would result in less issues with dead fish and short-term handling effects and tagging more fish might address issues with overall lower survival to downstream detection sites. He said more PIT tags might not be an issue; however, the cost of additional acoustic tags might be an issue. Buchanan agreed tag and receiver costs can be a factor in these studies. She noted that PIT-tag studies do not estimate project survival because those studies examine juvenile bypass system to juvenile bypass system and not tailrace to tailrace. Truscott said PIT-tag studies still examine a ratio. Buchanan agreed but explained that the detection locations for PIT-tag studies (juvenile bypass system) do not exactly align with the project and will always include some survival from the previous project. She said in this presentation, she will always be referring to acoustic tags. *(Note: Buchanan later indicated that upon further consideration, she agrees with Truscott that the ratio from PIT tags can be used to estimate project survival, provided that the model assumptions are met.)*

Slide 5

Buchanan said this is the list of assumptions common to all paired-release model studies. She said one cannot adjust for an assumption at the time of data analysis; therefore, it is important to think about these assumptions when designing a study.

Slides 6 to 7

Buchanan said each assumption includes considerations, as well as actions to take to prevent from violating the assumption or to determine how much in violation one is with the assumption. She reviewed considerations and actions for *Assumption #1: Test fish representative of population of inference*. She noted that good documentation of fish selection is key to defend against criticisms, and she reviewed histograms that compare fish lengths of acoustic-tagged subyearling study fish with run-of-the-river (ROR) fish.

Truscott asked if fish are not the healthiest but are representative of the run, is it really representative to remove injured fish from the study? He asked further, how does one not bias the study results unless the same quality of fish are included in each release group? Lance Keller agreed and said it can also be difficult to design a study to make sure the results are due to project effects and not a function of hatchery effects. Truscott said because the evaluation is based on a ratio, it seems this bias can be removed so long as there is equality between the release groups. Buchanan agreed if poor-quality fish are represented in both release groups this will cancel out. She said if a hatchery population is what one wants to make inference to, these fish need to be included in the sample and project survival will be estimated for this population. *(Note: Buchanan later indicated, upon further consideration, that the effects of using poor-quality fish will cancel out only if those effects are expressed equally between the upstream and downstream release groups. If the effects are expressed more in the upstream release group [e.g., stronger tag burden effects among poor quality fish], then the estimate of project passage survival will be negatively biased [for higher quality fish] even if both releases have the same proportion of poor-quality fish [i.e., representative sampling]. Both releases should have the same distribution of fish condition.)*

Slides 8 to 9

Buchanan reviewed considerations and actions for *Assumption #2: Test conditions representative of conditions of interest*. She said, for example, an unusually high-water year or drought year would not be representative of normal conditions and would not be ideal for a study.

Truscott said the HCPs stipulate conducting a validation study every 10 years, which limits the options to 1 year. Tom Kahler added, however, that validation studies consider a multiyear average, and Keller said a flow duration curve is also applied to each individual study included in a 3-year survival average.

Slide 10

Buchanan reviewed considerations and actions for *Assumption #3: Release sizes known exactly*. She emphasized the importance of scanning tags before release and also scanning recovered shed tags.

She said if fish are assigned to the wrong release group this will negatively impact the survival estimate.

Slide 11

Buchanan reviewed considerations and actions for *Assumption #4: Detection events correctly coded*. She said to differentiate true detections from false positive detections arising from ambient noise or tag collisions, one needs to implement a signal processing program. She said UW has a software program for processing data based upon Juvenile Salmon Acoustic Telemetry System (JSATS) and other tags. She said the program analyzes the number of tag pings and intervals. She said the program is complicated to implement.

Truscott asked how studies differentiate between alive and dead fish. Buchanan said there are filters for data implanted by the researcher; for example, those based on assumed behavioral differences or a statistical process based on movement behavior. Truscott asked if there is a difference in the tag signal. Buchanan said not generally; however, tag manufacturers have developed predation tags that ping differently when the tag comes in contact with stomach acid.

Slide 12

Buchanan reviewed considerations and actions for *Assumption #5: Fate of each fish independent*. She noted that tag collision is fairly uncommon with JSATS tags. She also recommended not positioning a receiver array directly downstream of a release location.

Slide 13

Buchanan reviewed considerations and actions for *Assumption #6: Prior detection history has no effect on subsequent survival and detection*. She said this consideration came out of bird banding studies where one must re-handle a bird to read the band, which might affect subsequent survival. She said the thought was the same with fish although less of an issue for acoustic tags, which do not require re-handling to detect fish. She said one can test for violations of this assumption using tests developed by Burnham et al. (1987)[2]; however, because acoustic tags have high detection probabilities these tests are not useful in this case. The Burnham tests are necessary for PIT-tag studies. She said to avoid violations of this assumption, researchers should think about the placement of the receivers. She said for example, if two detection sites are located upstream and downstream from each other and do not span the entire migratory channel, fish detected at the upstream site will have a different detection probability compared to the downstream site. She said this type of scenario results in biased detection probability (generally negative bias) and biased

[2] Burnham, K. P., D. R. Anderson, G. C. White, C. Brownie, and K. H. Pollack (1987). Design and analysis methods for fish survival experiments based on release-recapture. American Fisheries Society Monograph 5.

survival (positive bias). She said nothing can be done to correct this in the statistical analysis so this needs to be considered and addressed when designing the study.

Slides 14 to 15

Buchanan reviewed considerations and actions for *Assumption #7: All fish have same survival and detection probabilities*. She said the CJS model is generally robust to violations of this assumption. The robustness of the model to failures of this assumption can be tested by conducting a simulation study. She said in the example on slide 15, the study used a single release with two detection sites and survival was estimated through one reach (S_1). She said the single release was broken into two groups of equal size (Group 1 and Group 2 each with 10,000 fish), and the study simulated datasets under different scenarios to determine similarities or differences between groups. She said then an estimate of survival (or expected survival) [$E(\hat{S})$] and average of all datasets (or actual survival) ($\hat{\hat{S}}$) were calculated. She said in each case, the expected survival and actual survival were really close. She noted the low detection probabilities (p_1) ranging from 0.10 to 0.20, which she said is applicable to PIT-tag studies.

Ferguson asked what the lambda (λ) represents, and Buchanan said this represents the joint probability of: 1) surviving from the first detection site to the second detection site; and 2) being detected on the second detection site, conditional on having survived to the first detection site.

Peter Graf (Grant PUD) asked if there is a short-term receiver outage does this invalidate the data? Buchanan said this depends on how long the outage is relative to the duration of the detection period. She said, for example, a 2-hour outage over a 2-week detection period is not a big deal; however, a 2-hour outage over a 24-hour detection period might be more significant. She said one consideration is the λ parameter cannot be too small or this can lead to bias in the survival estimate.

Slide 16

Buchanan reviewed considerations and actions for *Assumption #8: Releases share same survival processes in reaches in common*. She reviewed the paired release-recapture model for estimating project passage survival. She said the first release (R_1) provides an estimate of the joint probability (S_1) of surviving through the project and through the tailrace to the first detection site and must be adjusted for survival from the tailrace to the detection site in order to give project passage survival. She said the second release (R_2) provides an estimate of the probability of survival from the tailrace to the first detection site (S_2). She said if fish from the two releases have the same probability of survival from the tailrace to the first detection site, then the ratio of the survival probabilities estimated from the two releases (S_1/S_2) is project passage survival. She said if the two releases do not have the same probability of survival between the tailrace and the detection site, then the ratio will be biased for project passage survival. She said one possible reason fish from the two releases might not have common survival in the common reach is if the fish are experiencing different environmental conditions when the fish are in the reach. She said to avoid this, the release timings should be staggered so that the downstream fish are released during the time when fish from the upstream release are expected to be passing through that reach.

Truscott said, for example, a study is targeting 80% of all migrants and those migrants are experiencing different flow regimes over the migration period, or the majority of fish pass in the first 30% of the migration period. He asked what exactly should the releases mimic? Buchanan said with the ratio this does sometimes make a difference. She suggested calculating a season-wide estimate that pools the releases across the season or take a weighted average of release-specific estimates. She said both should have the same results in expectation. Truscott said it seems if the bulk of fish pass during a specific period this would result in a different estimate compared to taking an average. Keller said the important thing is to align the release and migration timing. He said, for example, sockeye salmon below Wells Dam take 18 hours on average to reach Rocky Reach Dam and so long as the releases in the tailrace are at the same time across the entire study these factors should tease out.

Graf said these survival studies want the final results to be representative of the run at large, and he asked if this means the releases need to be weighted more? Buchanan said this is a good question and she is unsure, but she believes U.S. Army Corps of Engineers (USACE) studies pooled data across releases through time (R_1 and R_2 were pooled across the season). She said for PIT-tag survival studies, data were pooled on a daily basis.

Kahler said Douglas PUD has reported treatment and control releases within each replicate separately as a single release. He said survival was reported for: 1) pooled Okanogan and Methow releases (treatment); and 2) tailrace releases, for each replicate. He said survival for each pooled release treatment was divided by the survival for the control release for each replicate, and then the overall average survival was weighted.

Truscott asked how to calculate an estimate based on high survival when there is a low abundance of ROR fish. Buchanan replied: by taking a representative sample of the run through time, weighted more to the times when most fish are migrating. Keely Murdoch said she recalls having pre-planned releases fixed through time. Kahler agreed and said because it is unknown how the migration will turn out. Truscott asked then, if this would be a valid study? Murdoch also asked if the migration is normally distributed and releases are equal, but at the peak of migration there is higher or lower survival, will this bias the results? Kahler said for every release group there was an average travel time with travel-time distributions that overlapped with the distributions from other release groups, essentially a mass of fish from all releases that combined at one point. He said it would not be possible to implement an in-season tailoring of the releases to match the run, because one cannot tell where you are in the distribution at any point in time until the run is over. Keller suggested monitoring survival on a weekly basis and said it is not uncommon to see a decrease in survival on the front end and back end of the migration. He said from a predator saturation perspective, a lot of ROR fish are present in the middle of a juvenile outmigration compared to the beginning and the end. Buchanan suggested comparing study dates to run timing (e.g., slide 9). She said this would be a post-hoc analysis, but it would be based on historical averages. She said the curve on slide 9 is fairly well-representative and if the study is conducted too early or too late the sample size would have undue weight.

<u>Slide 17</u>

Buchanan continued discussing *Assumption #8: Releases share same survival processes in reaches in common*. She said when study fish are released in the river channel there is concern about releasing the fish in an area of high or low mortality, which can result in a positive or negative bias to the estimate. She said this can be assessed by comparing survival to a downstream site for each release across the river channel. She said in the example on slide 17, there is no strong evidence of a mortality hotspot.

<u>Slide 18</u>

Buchanan continued discussing *Assumption #8: Releases share same survival processes in reaches in common*. She said these plots examine the distribution of arrival timing. She said the hope here is for the peaks of the curves to align (for the modes to align).

<u>Slide 19</u>

Buchanan reviewed considerations and actions for *Assumption #9: Fish either migrate downriver or die*. She said if a fish does not appear at the end of a reach the model cannot distinguish between whether the fish died or did not migrate. She said if residualization occurs (i.e., migration delay past the end of the study), the estimate of project survival will be biased. She said actions to address this concern include using only active migrants and obtaining residualization-corrected estimates. She said the latter can be done through mobile surveys or an augmented acoustic-tag study design (extra receivers). She noted this cannot be done with PIT-tag studies because mobile tracking cannot be used with residualized PIT-tagged fish. She said even with good detection rates the problem is in interpreting the data.

<u>Slide 20</u>

Buchanan reviewed considerations and actions for *Assumption #10: No tag failure*. She emphasized the importance of testing tag life concurrent with the study. She said some tags lose battery life on the shelf or the tag can accidently be turned on during shipping. She said in one study, by the time tagging came along, these tags had only 4 days of battery life instead of 24 or more days. She said the only way to salvage a year of study is to conduct a tag-life study concurrent with the tagging and release of test fish and tell the manufacturer what is wrong so the vendor can fix the problem and send new tags.

Slide 21

Buchanan continued discussing *Assumption #10: No tag failure*. She said on the left graph, the black markers show the time of tag failure, which fit the tag-life curve really well. She said the average tag-life is 24 days. She said on the right, a tag-life curve was compared to tag detection times, particularly to the arrival distribution of tags at detection sites. She said each curve represents the cumulative arrival timing of tags at different detection sites. She said for a study you want the arrival to occur before the tag expires. She said if a lot of tags arrive dead (23 days or more in this case) this cannot be corrected, but a smaller amount can be corrected.

Graf asked how to determine whether a fish arrived past 24 days. Buchanan said if the fish arrives on Day 28, there is little likelihood for detection because the tag is probably dead. She said, however, if a fish arrives on Day 23, there is a 50% chance of detecting the fish based on available tags. She said if a lot of fish are arriving late, this indicates a problem. She said a tag-life adjustment can be applied if fish are arriving at the shoulder. Graf asked if the curve is assuming all tags are detected. Buchanan said the curve assumes the observed tags are representative of travel times.

Graf asked if the tag-life adjustment applies with a unimodal distribution of arrival times or does this only work with a uniform distribution of migration time. Buchanan said the tag-life correction factor is based on the average travel time for fish in a release group. She said if the average time is not a good representation, then the tag-life correction factor is not good either. She said a correction factor can be applied to a bimodal distribution, but it would have a large standard error.

Slide 22

Buchanan continued discussing *Assumption #10: No tag failure*. She reviewed each bullet on slide 22. Ferguson asked about tag lots. Buchanan explained that the tag lot indicates what day or group a tag is made on. She said some vendors do not send this information and then tags are assumed to be from one lot. She said different lots can have different ping rates or settings, which require a different tag-life study. Sample size for the tag-life study should be from 50 to 100 tags per tag lot.

Slide 23

Buchanan reviewed considerations and actions for *Assumption #11: No handling or tag effects that could distort survival studies*. She said tag-burden effects can get worse over time. She said Dr. John Skalski calls this the “backpack effect,” where over time, the burden of the tag on the test fish gets heavier (i.e., the fish gets fatigued by the burden over time). Buchanan said the best solution is to avoid tagger effects altogether by using well-trained surgeons and consistent tagging teams.

Slide 24

Buchanan continued discussing *Assumption #11: No handling or tag effects that could distort survival studies*. She said this graph shows estimates of common survival; specifically, it shows survival from a common starting point and moving downstream. She said in this example, the cumulative survival decreases as fish move downstream and the problem here is one release is decreasing more than the other, which is an indication of tag burden effect or tagger effect. She suggested creating this type of plot for each tagger, and if the upstream release for a tagger shows a steeper decline in cumulative survival than the composite upstream release, then the fish tagged by that tagger should be removed from the study, otherwise it will be bias the study results.

Slide 25

Buchanan continued discussing *Assumption #11: No handling or tag effects that could distort survival studies*. She said in this case, Tagger A always tags 20% of fish, Tagger B always tags 40%, and Tagger C always tags 30%. She noted these amounts are not the same, but they are consistent with the same tagger team (i.e., stable tagger team throughout entire season).

Slide 26

Buchanan continued discussing *Assumption #11: No handling or tag effects that could distort survival studies*. She said this graph demonstrates a tag burden effect where the cumulative survival is plotted for different releases. She noted the difference in the slopes of the curves moving downstream. She said on the right, the cumulative survival for the black line is decreasing more than the others, which indicates tag burden effects, where the black line represents the farthest upstream release. This means that fish from the farthest release upstream should not be used to estimate survival far downstream.

Slides 27 to 30

Buchanan said the next few slides consider estimating residualization in subyearling studies using single release and paired-release models. She said there are three possible fates for fish: 1) migrate and survive; 2) stop migrating and survive; or 3) die. She said the probability of migrating and surviving can be estimated using a single release CJS model [$\phi =$ Prob(migrating & surviving)]. She said the estimate from the CJS model is a product of the combination of migrating and surviving (= $\Psi \cdot S_{\text{MIG}}$). She said the probability of residualizing and surviving [$\delta =$ Prob(residualizing & surviving)] is $(1 - \Psi) \cdot S_{\text{RES}}$. She said, however, one cannot separate the probability of residualizing (Ψ) from the probability of surviving (S_{MIG} for migraters and for S_{RES} residualizers).

Ferguson asked if there have been studies to estimate residualization. Buchanan said there have been studies to estimate delta (δ), but not of actual residualizing. She said UW conducted a study in the Lower Monumental Dam pool and Grant PUD also conducted a study to estimate delta (δ). Graf said the study conducted by Grant PUD used arrays (rather than mobile tracking) and did not work well. Buchanan said the Lower Monumental Dam study also used fixed site detections in the reservoir, but the data structure did not allow separating the probability of residualizing from the probability of surviving. She said the study was able to get an overall estimate of phi (ϕ) and delta (δ) and total survival ($S = \phi + \delta$). She noted that both δ and S are time dependent.

Buchanan said one can attempt to estimate the joint probability of residualizing and surviving (δ) by either conducting at least two mobile surveys or using detections from a dense array of acoustic receivers to obtain an estimate of the abundance of tagged fish ($\widehat{N}$) still in a study reach and alive at the end of the migration period or study. She said the study design would need to have rules to differentiate between alive and dead fish or have nodes.

Slides 31 to 35

Buchanan said a paired-release CJS model isolates estimated project survival in the absence of residualization by calculating the ratio of survival estimates from two groups. She said if there is residualization, the model estimates the joint probability of migrating and surviving through the project ($\Psi_1 S_{MIG,1}$) similar to a single release model, but she also pointed out that only a paired-release model accounts for short-term handling effects and mortality between the tailrace and the detection site. She said if test fish residualize, this results in a negative bias in the project survival estimator. She said this model also assumes both releases have the same probability of migrating through the second reach, which may or may not be the case. She said ultimately, the model assumptions may not be realistic. She said taking the ratio of total survival from the two releases does not help because nothing cancels out in the ratio of total survival estimates resulting in no useful interpretation. One option is to use only active migrants ($\Psi = 1$).

Truscott said, as he has stated before, he does not agree with the HCPs' stipulation to only study active migrants. He said to only study active migrants is not an accurate representation of project-level effects. He asked, for example, if fish are collected at Rocky Reach Dam and randomly assigned to R_1 or R_2, will the probability of residualizing be different or equal if this is calculated by comparing ratios? Buchanan said the assumption is the probability of residualizing will be the same between two releases and if this is the case, the project survival estimate will still be of the joint probability of migrating and surviving. She said regarding compliance standards, if the standards are not met there is no way to determine if this is because the fish died or residualized. Truscott said if there is equal probability of residualizing, the assumption is the larger release group will have a higher probability of residualizing. Buchanan said not necessarily. Graf said the probability of residualizing will be the same in the two releases and will cancel out of the ratio. He said this is the same with sick fish. He said there are still the same proportion of sick fish and this does not cancel out the effect of sick fish, but it cancels out the bias. Truscott said if the overall survival is 50% and there is a 5% difference between R_1 and R_2, the PUD mitigation would be 5%. Graf said it is not the difference, it is a ratio. He said the 50% value includes the fish that residualize. Murdoch said if the study uses ROR fish that residualize this is part of the effect. She said if active migrants residualize the assumption is these fish would have residualized anyway. She said if residualizing is natural to this group of fish this is the proportion the study is trying to represent. Buchanan agreed but said this is not an estimate of pure survival; rather, it is the product of two things, migrating and surviving. She said the paired release is not going to include the survival of fish that residualized and cannot only estimate survival; therefore, if the survival standard is not met, the study cannot determine if this is because the fish died or residualized. She said the issue is how to apply the analyses to the standard.

Keller said fish from R_1 and R_2 have two different distances in order to migrate through the study area based on their release location. He said fish from R_1 have more time to manifest residualization, and he asked if the assumption is saying fish from R_1 and R_2 have equal probability of residualizing? Buchanan clarified the assumption only applies to the common reach (i.e., between the tailrace and the first detection site). Keller said, so residualization before a common reach is a bias. Buchanan said the bias for project survival is relative to survival for active migrants. If the two releases have the same probability of residualizing and surviving in the common reach, then the project passage estimate will be biased for true migrant survival in the project but will be unbiased for the joint probability of migrating and surviving through the project. She said one would need to conduct a mobile survey to get at residualizing and she reminded the HCP Coordinating Committees that there need to be rules during these surveys to differentiate live versus dead fish. Kahler asked how to distinguish between foraging and a predator? Buchanan said if the fish is really just foraging this may be a problem. She suggested considering how long the tag has been in one location. She said if a tag is stationary one can assume the fish is dead. She said even if there is evidence of residualizing, these fish cannot be used to get an adjusted estimate of project survival. She said the analysis methods account for non-detection under the modeling assumptions, but low detection probabilities introduce imprecision in the estimate and can introduce bias if detection probabilities are low enough. Graf agreed and added that if psi (Ψ) does not equal one this will negatively bias the survival estimate when the study is under the assumption that two groups have the same probability of migrating in a shared region. He said if there are different probabilities of migrating there will be bias in one or another direction depending on the psi (Ψ) from one group.

Slides 36 to 38

Buchanan said the next few slides review USACE subyearling Chinook salmon studies. She reviewed the survival requirements in the Federal Columbia River Power System (FCRPS), noting that FCRPS survival standards are different from those in the HCPs in that FCRPS standards refer to a different metric (dam passage survival), have different standards for subyearlings compared to yearlings, and have more rigorous precision standards. She said studies in the FCRPS use a virtual/paired-release design (or "viper" [ViPRe]) to estimate survival through a dam. She said fish are released upstream of a dam (R_1) where the fish have a chance to express handling and tagging effects and distribute naturally across the river channel. She said a three-dimensional (3D) array of receivers is used to define when and where a fish arrives at the dam and define a virtual release group (V_1). She said the study can estimate resident time in the forebay, route of passage, and survival based on the last known location of the fish. She said receivers should not be located in the tailrace to avoid detecting dead fish and suggested moving the receivers downstream about 20 to 50 rkm. She said the design calculates an adjusted estimate of survival from V_1 by calculating the probability of survival through the tailrace. She said the design cannot use only one release to compare to V_1 because this compares new fish to old fish. She said instead, a paired-release (R_2 and R_3) provides an estimate of surviving between the dam and the first detection site (marked P_{11} on slide 38). The paired release is used to adjust the estimate of survival from V_1 to get an estimate of dam passage survival.

Slide 39

Buchanan reviewed estimates of dam passage survival of subyearling Chinook salmon for seven FCRPS dams. She said the largest and smallest values are bolded to clearly show the range. She noted that the smallest value is about 91% at Little Goose Dam in 2013 and the largest is about 98% at Lower Monumental Dam in 2012. She said the overall average, about 94%, is noted at the bottom of the table. She said the HCPs stipulate 93% project passage. She said if Grant, Chelan, and Douglas PUDs' dam passage is similar to these FCRPS dam passage values for subyearlings, meeting 93% project passage for subyearlings might be challenging.

Slide 40

Buchanan reviewed an example of a release–recapture design for studying subyearling Chinook salmon in the mainstem in 2012. She said the goal of the study was to estimate dam passage survival. She said this study was conducted at consecutive dams which means it could be implemented efficiently with only 9 releases instead of 12 releases. She said this study design could also estimate project survival by comparing tailrace releases in consecutive tailraces. She said this design still included probabilities of migrating and surviving, which are potentially negatively biased for survival.

Slide 41

Buchanan reviewed acoustic-tagged, paired-survival estimates from various years of study at FCRPS projects. She noted a low of 67% at John Day Dam in 2014, to a high of 96% at McNary and Bonneville dams in 2012. She also noted the McNary Dam study was a mid-reservoir release. She said the average project survival was only 86% and it is not clear if this was due to mortality in the reservoir or to the possibility of residualizing in the reservoir. She said dam passage estimates are unbiased for residualizing because subyearlings do not residualize during dam passage.

Slides 42 to 44

Buchanan reviewed a 2007 acoustic tag study estimating subyearling Chinook salmon survival through the Lower Monumental Dam reservoir. She said fish were released in the Little Goose Dam tailrace. She said the initial release was defined based on fixed site acoustic receivers in the reservoir (virtual release). She said survival was monitored from the virtual release site through the reservoir. She said this was repeated for seven groups. She said fixed site nodes were used to estimate the abundance of residualizing fish at the end of each 8-week sampling period.

Buchanan said slide 44 shows estimates for the weekly release groups and pooled results for study totals. She said the light gray in the plot shows the probability of migration and survival. She noted there is little variability between release groups. She said the white in the plot shows the probability of delay (residualizing) and surviving, which increased toward the end of the study. She said the black in the plot shows the probability of mortality, which could represent a mortality as a migrant or mortality as a residualizer. She said the results for the probability of residualizing and surviving (white bars) and for mortality (black bars) are time dependent; however, the plot is not showing the level of time-dependency. She said the pie chart shows the combined results over the season for the probability of migrating, surviving, and delay in weighted averages. She said migration and delay combined is about 47%, and she noted there is quite a bit of mortality. She also noted that these data only represent the portion of the reservoir where receivers were located.

Buchanan said Grant PUD conducted a similar study but did not have as much residualization. Graf said there was a bit of loss; however, this could not be attributed to death or residualization. He said regarding dam survival, Grant PUD conducted studies in the same years and had similar numbers.

Truscott said both dam passage and survival studies were conducted with taggable-sized subyearlings, and he asked if there are fry in the Rocky Reach Dam bypass. Keller said there are, and Truscott said this is another issue. Truscott said these designs are not studying survival of a population; rather, they only study taggable-sized fish.

Slides 45 to 47

Buchanan reviewed subyearling PIT-tag survival results from Priest Rapids Fish Hatchery to McNary Dam. She said for joint probability of migration and survival, the estimates ranged from 46% in 2004 to 85% in 2016 and averaged 66%. Graf said the study fish were all fall Chinook salmon and there was no evidence of residualizing. Buchanan noted that these estimates are far from meeting the HCP standard. Graf noted that the study area is a long reach. Truscott recalled work conducted by Geoff

McMichael (Mainstem Fish Research) on natural subyearlings. Truscott said survival was also really low for McMichael, about 30%. Graf agreed and said McMichael and Ryan Harnish (Pacific Northwest National Laboratory) acoustically tagged wild fish and identified two mortality hot spots at the mouth of the Yakima River and in the McNary Dam forebay.

Buchanan reviewed subyearling Chinook salmon PIT-tag survival results from Lower Granite Dam to McNary Dam. She noted that these fish came from Lyons Ferry Fish Hatchery and were released upstream of Lower Granite Dam. She said the reach from Lower Granite Dam to McNary Dam is through four projects, so taking the fourth root of the survival to McNary Dam gives a per project survival ($\sqrt[4]{S}$). She said these results were considerably higher ranging from 84% to 98% and averaging 91%. She said, however, this still does not meet the HCP project compliance standard.

Slides 48 to 52

Buchanan said project survival (S_{MIG}) is not separately estimable. She said what is estimable is: 1) joint probability of migration and survival ($\phi = \Psi \cdot S_{\mathrm{MIG}}$); or 2) total survival ($\phi + \delta$), which is time dependent. She said phi (ϕ) can be estimated using a pair-release design; however, phi (ϕ) can only be estimated under perhaps unrealistic assumptions. She said, therefore, a statistical solution to subyearling Chinook salmon residualization may not exist. She then reviewed subyearling study design recommendations if one did want to attempt to study the estimable parameters and how one might attempt to estimate residualization.

Ferguson asked if a study design follows all of these recommendations, could the results potentially address the survival standard as stipulated in the HCPs? Buchanan clarified that there is still no statistical solution to address the survival standard as stipulated in the HCPs. She said there is still no way to tease out the desired parameters. She said what can be done is calculating an estimate of migration and survival, which can be maximized as far as the migration component can go by using actively migrating fish. She said there may still be a negative bias for actual survival itself if some fish are residualizing. She said if one conducts a study, the recommendation is to use a paired-release design bearing in mind the estimates will not necessarily be an unbiased estimate of survival because even with active migrants some study fish may still residualize. Graf also noted that subyearlings are really small earlier in the season and may be less likely to be active migrants. Buchanan agreed and said this is another issue.

Buchanan said one option is to instead estimate dam passage survival, which is presumably estimable based on USACE studies. She said instead of a paired-release design downstream of the tailrace (ViPRe design), a virtual release/dead fish correction (or ViRDCt) design puts receivers in the tailrace and releases dead fish with tags to estimate the probability of dead fish traveling downstream. She said this design, which releases fish at the dam, was tested at Lower Granite Dam in

2018. She said the results were comparable to the ViPRe design. She said there are advantages to the ViRDCt design; however, the results are not applicable to the HCP criteria.

Slides 53 to 55

Buchanan reviewed ideal study timing and spacing. She said regarding timing, consider an ideal tag-life based on what needs to occur during the tag-life and program the tags to last this long. She said detection of all tags needs to occur before the tag fails and a residualizing survey also needs to be conducted before a tag dies. She said when considering spacing of detection arrays, if the first detection site is too far downstream there may be an increasing expression of "backpack effect," and if the site is not far enough downstream this will result in false positives from detections of dead fish and unequal expression of handling effects. She said the graph on slide 55 shows the survival of two releases through space. She said the cumulative survival declines as fish travel farther. She said to look for a lack of parallelism, which would indicate tag burden effects and is likely to occur more towards the right side; the curves on slide 55 are parallel.

Slides 55 to 57

Buchanan reviewed a summary about the residualization issue. She suggested having nodes in place to conduct a post-study abundance survey. She said one can estimate migrating and surviving (ϕ) and not migrating and surviving (δ). She said using active migrants gets a design closest to 1 as possible ($\Psi_1 \approx 1$, $\Psi_2 \approx 1$). She noted that phi to phi ($\frac{\hat{\phi}_1}{\hat{\phi}_2}$) will estimate the joint probability of migrating and surviving through the project ($\Psi_1 S_{MIG,1}$) but assumes the probability of migrating is the same for two groups through a common reach. She said one option is to estimate total survival using the ratio of phi estimates and the estimate of residualization and survival from the project reservoir ($\hat{\delta}_{11}$).

Buchanan said alternatively, one can study dam passage survival to avoid the residualization issue. Murdoch asked if instead of just dam passage survival, can a study be set up to study both dam and total survival? She recognized this is still not the same as project survival, but the data could be useful to inform dam and total survival. Buchanan said yes, this is possible and said this is kind of what was being studied in the USACE studies, only those designs did not use in-reservoir nodes so there were no estimates of residualizing populations or total survival in the project. She said rather, these studies used the ViPRe design and consecutive dams to estimate the probability of migrating and surviving through the projects. She said one question to ask when considering a study design is, can one interpret the complement in a useful way? She asked, what does "1 – whatever is being estimated" mean? Murdoch said if one knows project survival and total survival, this would provide an idea of how big of an issue residuals and mortalities are outside of a project. Buchanan said the experience Grant PUD had makes her hesitant, i.e., they found that fish were not getting past the project and there was no evidence of residualizing. She questioned whether this was because the fish residualized and died before the post-study survey or died before residualizing? Murdoch said this would still provide an estimate of project survival, and Buchanan said but not an unbiased estimate of survival. Murdoch said one would still know dam survival and know how that parameter performed. She said if there is a big difference between total and dam survival this would indicate a problem with residualizing and mortalities. Buchanan said if there is not a big difference, then this raises a question when interpreting project performance because one cannot distinguish between residualization and mortality. Murdoch agreed but said this might provide the best information available.

Murdoch asked how much do projects and reservoirs affect residualization and the mortality of fish displaying different life histories? Kahler said at this point, there is no way to distinguish from what would happen without the project being present.

Discussion

Truscott said considering there are fry (or 40-millimeter fish) at Rocky Reach Dam, which are active migrants that cannot be tagged, this means there is no way to tag an accurate representation of the population. Graf said the issue is not that a study cannot be done; rather, with the current information and technology, there will be someone who is unsatisfied with the study (e.g., the sample is not representative, the study duration is too short, and unknowns about the tags, among other things). Truscott agreed and said there needs to be an understanding that a study cannot be perfect and the reason for studying subyearlings is to have something more tangible.

Buchanan said even if a smaller fish can be tagged and as much as these fish may be less likely to migrate, the interpretation issue will be bigger. She said if the results indicate that survival is high, this is fine; however, if results are low, then why? She questioned if low results are a project effect or tag effect? Truscott also noted that subyearlings are emigrating and rearing at the same time but moving downstream slower compared to yearlings, and he asked how to classify an active versus non-active migrant?

HCP Coordinating Committees and PRCC representatives thanked Buchanan for sharing the presentation.

Ferguson asked, given the information shared during today's meeting, if Chelan PUD plans to request approval of another 3-year Statement of Agreement (SOA) during the next HCP Coordinating Committees meeting on August 27, 2019? Keller said he did not hear anything today to change Chelan PUD's view expressed during recent meetings and he believes an SOA is the next logical step. He said, however, Chelan PUD does not want to draft an SOA if the Rock Island and Rocky Reach HCP Coordinating Committees desire additional discussion. He recalled Chelan PUD's proposal to draft a reboot of the last SOA, including retaining the quarterly check-in language to capture changes or new opportunities at estimating project survival for subyearlings. Truscott asked when the current SOA expires, and Keller said September 29, 2019. Truscott suggested having another discussion on this topic before voting on an SOA. Murdoch agreed and said it seems there may be parameters that can be measured and could be useful. Keller agreed further discussion could be useful.

HCP Coordinating Committees representatives will prepare technical questions and considerations concerning the feasibility of conducting subyearling Chinook salmon studies with the current information and technology available to date, for discussion with Buchanan and Skalski during the HCP Coordinating Committees meeting on August 27, 2019.

II. Welcome

A. Review Agenda (John Ferguson)

John Ferguson excused Peter Graf and Tom Skiles (Columbia River Inter-Tribal Fish Commission) and welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. No additions or changes were requested.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft June 25, 2019 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. HCP Coordinating Committees members present approved the June 25, 2019 meeting minutes, as revised. National Marine Fisheries Service (NMFS) and the CCT abstained, because NMFS and CCT representatives were not present during the June 25, 2019 meeting. *(Note: Chad Jackson provided Washington Department of Fish and Wildlife's [WDFW's] approval of the minutes via email on July 22, 2019.)*

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on June 25, 2019, and follow-up discussions, were as follows. *(Note: Italicized text corresponds to agenda items from the meeting on June 25, 2019):*

- *Lance Keller will review subyearling Chinook salmon sampled at the Rocky Reach Juvenile Sampling Facility (RRJSF) during the summer spill season at Rocky Reach Dam, to determine the following: 1) whether the index samples collected represent overall passage trends based on PIT-tag detections in the bypass across the season, notably during high flow years such as that experienced in 2018; and 2) whether any adjustments are needed while also maintaining* *continuity with historical data in the Columbia River Data Access in Real Time database (DART; Item I-C).*

Keller provided the review of subyearling sampled at RRJSF by email following the meeting on June 25, 2019, as distributed to the HCP Coordinating Committees by Larissa Rohrbach that same day.

- *Kirk Truscott will contact Lance Keller to further discuss options to increase attraction flow through the cul-de-sac area in the Rocky Reach Dam forebay (near Turbine Units C1, C2, and C3) while Turbine Units C1 and C3 are offline for maintenance (Item I-C).*

  Keller said Turbine Unit C3 is back in operation, which closes this action item.
- *Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item I-C).*

  This action item will be discussed during today's meeting and will also be carried forward.
- *Douglas PUD will review available PIT-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item I-C).*

  Tom Kahler said the PIT-tag data from the Methow Fish Hatchery and Twisp River releases have only recently been uploaded, and have not yet been analyzed. This action item will be carried forward.
- *The following action items pertain to the Decision Item whether to approve Douglas PUD's request not to tag with coded wire tags (CWTs) the component of brood year (BY) 2018 summer Chinook salmon raised at Wells Hatchery that will be used for the 2020 Survival Verification Study (2020 Survival Study) because they will be tagged with PIT-tags and adipose clipped (Item II-A) (Note: This Decision Item will be brought forward to the July 23, 2019 meeting agenda):*
  - *Tom Kahler will inform the HCP Coordinating Committees of the planned dates in July when CWT tagging will occur. (Note: Kahler stated via email on June 26, 2019, that CWT tagging will occur in August, as distributed by Larissa Rohrbach the following day.)*
  - *Tom Kahler will respond to Keely Murdoch's initial questions about the effects of a decision not to tag with CWTs the 2020 Survival Study fish on the following:*
    - *Monitoring and evaluation studies*
    - *Estimates of smolt-to-adult ratios (SARs)*
    - *The collection of harvest information*
  - *Chad Jackson will determine whether there are concerns associated with not coded wire tagging the study fish from an ocean harvest standpoint.*
  - *Larissa Rohrbach will distribute draft meeting minutes from this agenda item to Kirk Truscott and Scott Carlon following the meeting for their immediate consideration. (Note:*

Rohrbach emailed a draft of the relevant minutes on June 26, 2019, to Truscott and Carlon, Cc Tom Kahler, John Ferguson, and Kristi Geris.)

- *HCP Coordinating Committees representatives will email their own or their Hatchery Committees representative's comments and questions to Larissa Rohrbach for distribution by next Wednesday July 3, 2019. (Note: Per Tom Kahler's email on June 26, 2019, a CWT tagging date in August allows the issue to be brought to the HCP Hatchery Committees in the regular monthly meeting on July 17, 2019.)*
- *The HCP Coordinating Committees will vote on whether to approve Douglas PUD's request via email or at the next meeting depending on when a decision is needed for CWT tagging operations. (Note: Tom Kahler stated via email on June 26, 2019, that CWT tagging will occur in August, as distributed by Larissa Rohrbach the following day.)*

This action item will be discussed during today's meeting.

- *Lance Keller will provide an update by email on the performance of the new Rocky Reach Dam C3 Unit Chesterton seals by Friday, June 28, 2019 (Item III-A).*
  Keller provided an update on July 19, 2019, which Kristi Geris distributed to the HCP Coordinating Committees on July 20, 2019.
- *Larissa Rohrbach will distribute by email the acoustic tag specifications sheets shared by Lance Keller following today's meeting (Item IV-A).*
  Keller provided the specifications sheets following the meeting on June 25, 2019, which Larissa Rohrbach distributed to the HCP Coordinating Committees that same day.
- *Lance Keller will provide additional information on the change in ATS Inc. acoustic tag weights with different battery types (Item IV-A).*
  Keller provided this information on July 22, 2019, which Kristi Geris distributed to the HCP Coordinating Committees that same day.

III. HCP Hatchery and Tributary Committees Update

A. HCP Hatchery and Tributary Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on July 16, 2019:

- *Lower Derby Fish Passage Project:* The Rock Island HCP Tributary Committee received a time extension request from Cascade Columbia Fisheries Enhancement Group (CCFEG). Because of a delay in completing final designs, CCFEG requested a time extension from December 1, 2019 to December 15, 2020. After discussion, the Rock Island HCP Tributary Committee agreed to the time extension.
- *General Salmon Habitat Program Proposals:* The HCP Tributary Committees received 13 proposals, including 12 cost shares with the Salmon Recovery Funding Board (SRFB). Before

evaluating the projects, the HCP Tributary Committees identified the unallocated balance within each Plan Species Account. In total, there is just under $10.5 million available to fund projects. As a result, the HCP Tributary Committees evaluated 13 proposals, including the 12 cost shares with SRFB, and six of the proposals were funded by the Rock Island HCP Tributary Committee at a cost totaling $1.2 million. By comparison, the total request was for $1.7 million in cost shares, with a total cost of $11 million. The proposal that was not a cost share was from WDFW for the 2019 Eightmile Creek Fisheries Assessment Project. The purpose of the project is to identify fish abundance, stream flows, and water temperatures to guide permitting and selection of a brook trout removal strategy for Eightmile Creek, a tributary to the Chewuch River. The HCP Tributary Committees were unable to make a funding decision and asked the sponsor to provide additional information and a revised budget, which does not include genetic analysis of brook trout and bull trout (non-Plan Species).

- *HCP Policy Committees Guidance:* Hillman said John Ferguson will discuss this topic, but in general, the HCP Tributary Committees were pleased with the guidance provided by the HCP Policy Committees.
- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on August 8, 2019.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on July 17, 2019 (*note: joint HCP Hatchery Committees/PRCC Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Goat Wall Acclimation Site Performance Update (joint):* The Yakama Nation (YN) provided a presentation on the performance of the spring Chinook salmon Goat Wall Acclimation Site, which is located on the Upper Methow River. Since using the site (2017), the YN has released between 25,000 to 30,000 spring Chinook salmon smolts from the site. Spring Chinook salmon survival within the acclimation pond has ranged from 98.0% to 99.9%. Smolt survival and travel times to McNary Dam are similar to those reported for Methow Fish Hatchery spring Chinook salmon.
- *Egg Treatment Study (joint):* Douglas PUD provided results from their study to evaluate the effects of salt, hydrogen peroxide, and formalin in controlling saprolegnia fugus infections on summer Chinook salmon eggs during incubation. The study found no difference among treatments and a control group. This result may have been because there is a low level of pathogens at the Methow Fish Hatchery where the study was conducted. Douglas PUD proposed to conduct a similar study at Wells Fish Hatchery where the incidence of saprolegnia may be higher.

- *Outplanting Spring Chinook Adults in the Chewuch River (joint):* Because of the low escapement of spring Chinook salmon to the Methow River basin, it is unlikely that spring Chinook salmon adults will be outplanted into the Chewuch River this year. This is a planned study to examine outplanting as an alternative to acclimation. Once escapements allow the study to be conducted, fish will be outplanted in areas where spring Chinook salmon are absent within the Chewuch River.
- *Wenatchee Spring Chinook Salmon Broodstock Collection (joint):* Sufficient broodstock has been collected for the Wenatchee spring Chinook salmon programs. However, most of the broodstock collected consist of hatchery fish. Therefore, crews are trying to collect more natural-origin fish for the programs.
- *NMFS Consultation (joint):* NMFS is completing their Finding of No Significant Impact for the Steelhead and Summer Chinook Salmon Environmental Assessments. Permits are currently going through internal review and hopefully will be signed soon.
- *Wells Summer Chinook Salmon Tagging for the 2020 Survival Study (Wells):* Douglas PUD informed the Wells HCP Hatchery Committee that the Wells HCP Coordinating Committee intends to conduct the 10-year check-in study using yearling summer Chinook salmon in 2020. The 110,000 summer Chinook salmon used for the survival study will be part of the Wells Fish Hatchery yearling summer Chinook salmon production. To reduce tagging and handling effects, Douglas PUD proposed to tag the survival-study fish with only PIT tags and adipose fin clips, but no CWTs. The Wells HCP Coordinating Committee asked the Wells HCP Hatchery Committee if there are any issues with the proposed tagging plan. For monitoring purposes and harvest evaluations, the Wells HCP Hatchery Committee recommended that all fish be tagged with CWTs. Those fish used for the survival study could receive a code different from the rest of the production fish. Thus, all Wells Fish Hatchery yearling summer Chinook salmon will be adipose clipped and CWT tagged. Those used for the survival study will also be PIT tagged.
- *2019 Hatchery Monitoring and Evaluation (M&E) Implementation Plan (Wells):* The Wells HCP Hatchery Committee reviewed and approved the 2019 Hatchery M&E Implementation Plan.
- *Expanded Wells Summer Chinook Salmon Production for the Southern Resident Killer Whale Population (Wells):* WDFW is preparing a proposal that will allow extra production of summer Chinook salmon at the Wells Fish Hatchery. The extra production is intended to benefit the Southern Resident Killer Whale population. The Wells HCP Hatchery Committee will evaluate the proposal to determine if the extra production will affect HCP production.
- *HCP Policy Committees Guidance (Wells, Rock Island/Rocky Reach):* Hillman shared with the HCP Hatchery Committees the guidance provided by the HCP Policy Committees to evaluate all decision items based on biological and technical merits, feasibility, and cost. Hillman said the HCP Hatchery Committees were not as pleased with this guidance, based on issues with

the *US v. Oregon* process. Kirk Truscott clarified the direction from the HCP Policy Committees was to evaluate a proposal based on technical merit, which does not mean to make or not make a funding decision. He said the decision is whether the project is fundable and if there is a policy issue the decision to fund is an HCP Policy Committees decision. *(Note: The HCP Policy Committees direction was not intended to take decision-making away from the technical committees, but to provide those committees an option besides a dispute whenever a policy issue interferes with decision making.)*

- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on August 21, 2019.

IV. All

A. HCP Tributary Committees Dispute Update (John Ferguson)

John Ferguson said the HCP Policy Committees convened an in-person meeting on July 9, 2019. He said there was good discussion and development of four action items. He said there was good progress in terms of isolating issues to those that are within and outside the HCPs. He said guidance was developed for the HCP Tributary, Hatchery, and Coordinating Committees. He said there was discussion and agreement about the successful implementation of the HCPs to date and a shared desire to continue this trend. He said the HCP Policy Committees agreed it would be beneficial to meet more often, perhaps annually around the time when the HCP annual reports are complete, to review the past year's activities and current topics. Tom Kahler and Kirk Truscott, who also attended the in-person meeting on July 9, 2019, said they had nothing further to add.

Ferguson reviewed the action items from the HCP Policy Committees meeting on July 9, 2019, as follows:

- Steve Parker (YN HCP Policy Committees Representative) and Cody Desautel (CCT Natural Resources Director) will discuss with their respective policy staff about convening the YN and CCT Tribal Councils to discuss potential paths forward for the Scaffold Camp Acquisition #2 Project, including third-party ownership.
- Tracy Hillman (HCP Tributary and Hatchery Committees Chairman) will communicate HCP Policy Committees guidance to the HCP Tributary and Hatchery Committees to base funding decisions on technical merit, and to notify respective HCP Coordinating and Policy Committees representatives of any potential policy issues needing to be addressed in those forums.
- Steve Parker and Cody Desautel will discuss with their respective policy staff about convening the YN and CCT Tribal Councils to: 1) attend a joint meeting and presentation by Chelan PUD, Douglas PUD, and YN and CCT HCP technical representatives about the function of the HCPs; and 2) provide guidance on land ownership issues that might impact implementation of the HCPs.

- HCP Policy Committees representatives will each discuss with their respective HCP Tributary and Hatchery Committees representatives the option of abstaining in lieu of a disapproval vote to preserve a policy position.

Ferguson said two of the action items concern land ownership issues, which the HCP Policy Committees spent a lot of time discussing. He said regarding the first action item, the HCP Tributary Committees meeting minutes from July 16, 2019, indicate that the YN purchased the Scaffold Camp property; therefore, this action item is a moot point.

V. Douglas PUD

A. DECISION: 2020 Survival Verification Study – Coded Wire Tags (Tom Kahler)

Tom Kahler said the Wells HCP Hatchery Committee recommended that all fish be CWT tagged and Douglas PUD agrees this recommendation can be incorporated into the study; therefore, this is no longer an HCP Decision Item.

B. Wells Project Subyearling Chinook Life-History Study 2011–2013 Draft Final Report (Tom Kahler)

The draft *Wells Project Subyearling Chinook Life-History Study 2011–2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019, and is available for a 60-day review with edits and comments due to Tom Kahler by Tuesday, July 23, 2019. Kahler said he wanted to provide an opportunity for the Wells HCP Coordinating Committee to ask final questions, and if the Committee has no questions or comments Douglas PUD can make a few editorial corrections, finalize, and distribute. Kirk Truscott said he will submit CCT comments on the draft report by Friday, July 26, 2019.

Douglas PUD will request approval of the report during the HCP Coordinating Committees meeting on August 27, 2019.

VI. Chelan PUD

A. Rocky Reach Dam Turbine Unit C1 and C3 Update (Lance Keller)

Lance Keller said Rocky Reach Dam mechanics are moving forward with the trunnion seal repair in Turbine Unit C1, with the unit being returned to service after the 2019 juvenile bypass season. He said there is a conflict in scheduling for the recommissioning of Turbine Units C9 and C1. He said crews have never conducted concurrent unit commissioning and he does not believe there are plans to try to do so. He said currently, he is unsure which unit will be prioritized.

Keller said Turbine Unit C3 was returned to service on July 17, 2019. He said he provided an update on Turbine Unit C3 on July 19, 2019, which Kristi Geris distributed to the HCP Coordinating Committees on July 20, 2019. Keller apologized for not providing an update by June 28, 2019, per his action item from the HCP Coordinating Committees meeting on June 25, 2019; however, he said the unit was tested and re-tested because there was direction from the senior team to continue to pursue both the new seals and hydraulically locking the blades into place as options, which caused a brief delay in the schedule. He said currently, the unit is operating with the Chesterton seals installed and everything is running fine with no observations of anything out of the ordinary. He said there are plans to remove Turbine Unit C3 out of service periodically to reassess the performance of the new seals; however, he is unsure about the schedule for this. He said the outage will likely be weeks and not months. He said he reviewed bypass counts pre- and post-outage for Turbine Unit C3 and there was no evidence of any change in the index counts. Kirk Truscott asked if Chelan PUD plans to include these data and dates in a report, and Keller said he will, and these data are also available on DART.

B. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said work continues to move forward on Turbine Unit B4. He recalled that parts needed to repair the unit (the rotor poles and hydraulic power unit) have been delayed and now the rotor spider is also delayed. He said the return to service date of fourth quarter of 2019 is still accurate.

VII. HCP Administration

A. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on August 27, 2019, to be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington.

The September 24 and October 22, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

List of Attendees

Name	Organization
John Ferguson	Anchor QEA, LLC
Kristi Geris	Anchor QEA, LLC
Tracy Hillman††	BioAnalysts
Rebecca Buchanan	University of Washington, Columbia Basin Research
Lance Keller*	Chelan PUD
Tom Kahler*	Douglas PUD
Scott Carlon*†	National Marine Fisheries Service
Jim Craig*	U.S. Fish and Wildlife Service
Patrick Verhey*†	Washington Department of Fish and Wildlife
Keely Murdoch*	Yakama Nation
Kirk Truscott*	Colville Confederated Tribes
Peter Graf¨	Grant PUD
Tom Skiles¨	Columbia River Inter-Tribal Fish Commission

Notes:
- * Denotes HCP Coordinating Committees member or alternate
- † Joined by phone
- †† Joined by phone for the HCP Tributary and Hatchery Committees Update
- ¨ Joined for the joint HCP Coordinating Committees and PRCC portion of the meeting

Attachment B

Considerations in the Design & Analysis of Subyearling Chinook Salmon Survival Compliance Studies – 2019

John R. Skalski, Rebecca A. Buchanan
University of Washington
School of Aquatic & Fishery Sciences

Outline

I. Paired release–recapture design
- Minimal requirements
- Model assumptions

II. Estimating residualization in subyearling Chinook salmon

III. Overview of USACE subyearling studies
- Virtual/paired-release design
  - Dam passage survival estimates
- *Post hoc* paired-release design
  - Project passage survival estimates

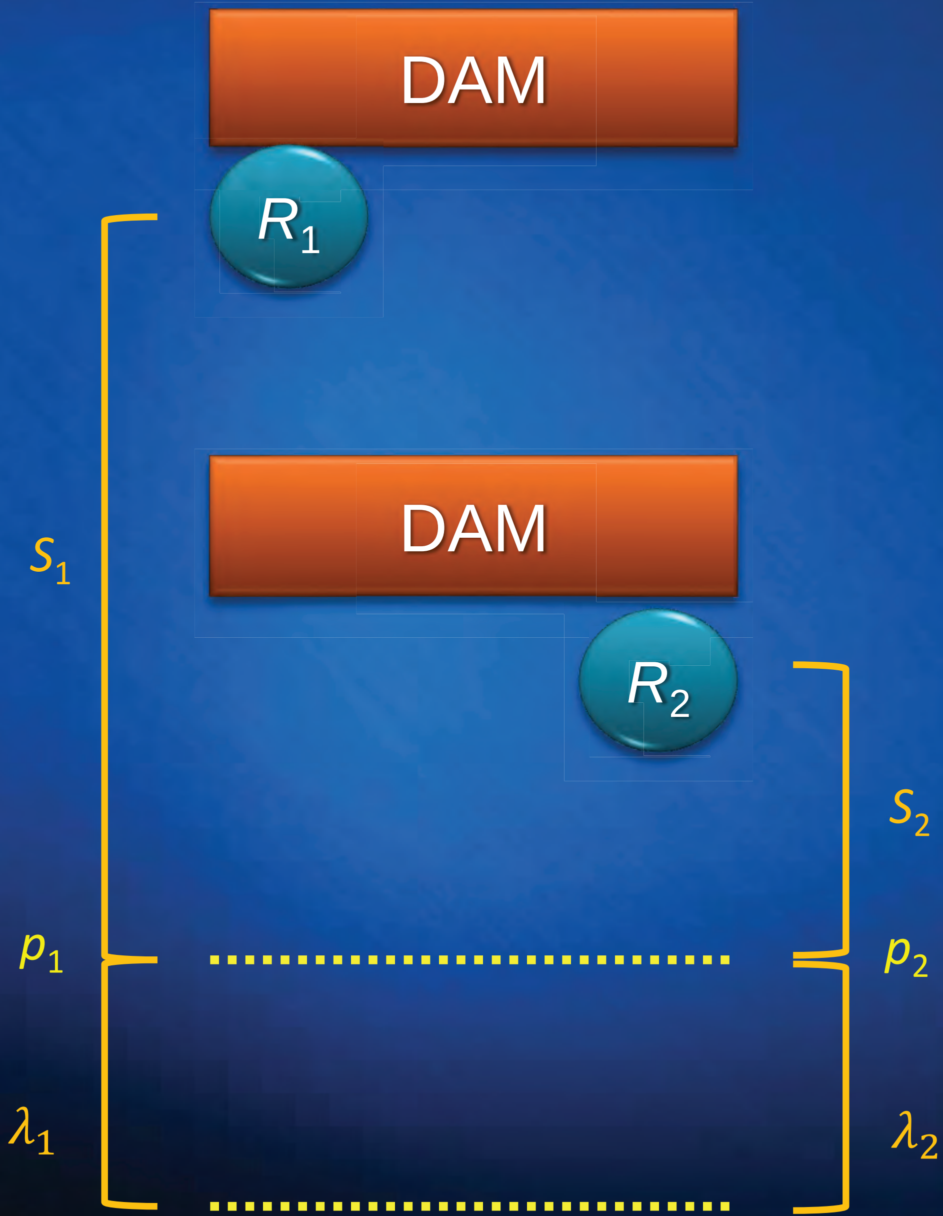
IV. Lower Monumental 2007 subyearling study

V. PIT-tag reach survival estimates

VI. Study recommendations

I. Paired Release–Recapture Design

Paired Release–Recapture Design: Estimation of Project Passage Survival



$$\hat{S}_{\text{Project}} = \frac{\hat{S}_1}{\hat{S}_2}$$

- Requirements
  - Control and treatment releases
  - Minimum of 2 downstream detection locations

Assumptions of Paired-Release Model

1. Test fish representative of population of inference
2. Test conditions representative of conditions of interest
3. Release sizes known exactly
4. Detection events correctly coded
5. Fate of each fish independent
6. Prior detection history has no effect on subsequent survival and detection
7. All fish have the same survival and detection probabilities.
8. Releases share same survival processes in reaches of common passage
9. Fish either migrate downriver or die
10. No tag failure
11. No handing or tag effects that could distort survival estimates

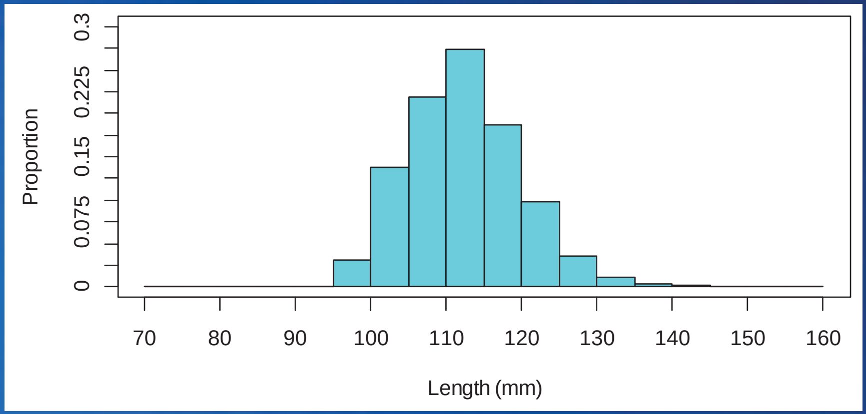
Assumption #1: Test fish representative of population of inference

- Considerations:
  - Wild vs. hatchery composition
  - Size distribution
  - Fish condition
- Actions:
  - Representative sampling of ROR fish
  - Limitations on minimum size for tagging (e.g., 95 mm with acoustic tag, potentially smaller with injectable tags)
    - Comparison of tagged and source fish
  - *A priori* rules on fish selection
    - % descaling
    - Injury
    - Document fish selected and rejected

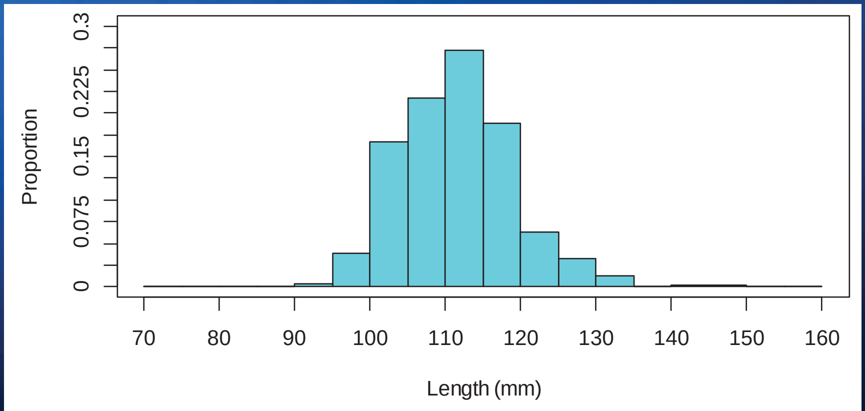
Assumption #1 (Continued)

Comparison of acoustic-tagged subyearlings with ROR fish, e.g., The Dalles, 2012

a. Tagged



b. ROR via FPC

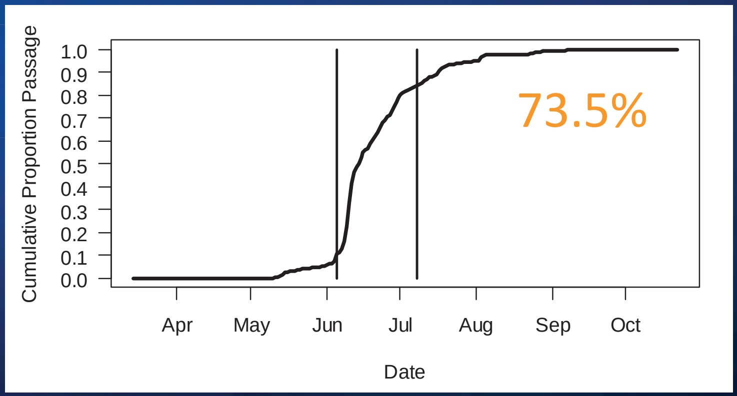


Assumption #2: Test conditions representative of conditions of interest

- Considerations:
  - Dam operations
    - Spill program
    - Juvenile bypass system operations
    - Powerhouse operation
  - Ambient conditions
    - River flows
  - Outmigration season timing
    - Release throughout outmigration
  - Diel patterns

Assumption #2 (continued)

- Actions:
  - Control dam operations
  - Selection of test years
    - Representative:
      - E.g., middle 90% of historical river discharges
    - Hydraulic diversity:
      - E.g., replicate studies at least 5% difference in hydraulic patterns
    - Monitor run timing:
      - Report % of run covered by study, e.g., LMN, 2013
      - Handling/tagging stops when water temperature > 18°C



Assumption #3: Release sizes known exactly

- Considerations:
  - Prerelease tag loss and/or failure
  - Tagged fish assigned to wrong release group
- Actions:
  - QA/QC procedures
    - Scan tags before release
    - Search for shed tags

Assumption #4: Detection events correctly coded

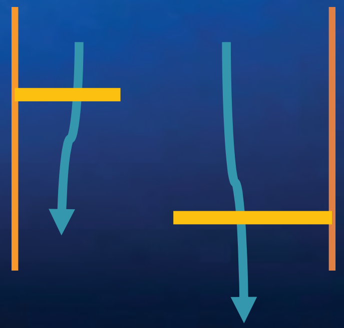
- Considerations:
  - Tag ID misidentification
  - Differentiating actual tag signals from ambient noise
  - Differentiating predation from alive detection events
- Actions:
  - Rigid signal processing criteria to avoid false-positive signals

Assumption #5: Fate of each fish independent

- Considerations:
  - Death of one fish does not affect the fate of another fish
  - Detection of one fish does not affect the detection of another fish
- Actions:
  - Assumption necessary to construct statistical models
  - Receivers capable of detecting many 10s of fish simultaneously

Assumption #6: Prior detection history has no effect on subsequent survival & detection

- Considerations:
  - Detection and rehandling could affect subsequent survival and detection
- Actions:
  - Acoustic tags do not require rehandling for detection
  - No post-detection bypass mortality as in PIT tags
  - Burnham et al. (1987) tests 2 and 3
    - Not useful because of high detection probabilities
  - Avoid poor receiver placement, e.g.,



Assumption #7: All fish have same survival and detection probabilities

- Concerns:
  - Heterogeneity in survival likely exists between fish
  - Route of dam passage may affect survival and detections
- Actions:
  - CJS model totally robust to heterogeneity in survival, e.g., estimates average survival
  - At high detection probabilities, CJS model also robust to heterogeneity in detections

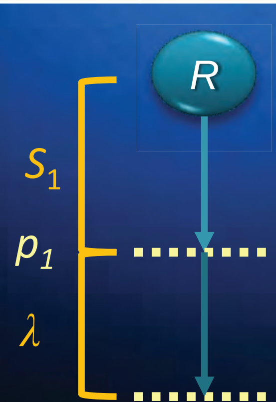
Simulation Study – Model Robustness

Assumption: All fish have equal probability of survival and detection

- Single release: Composed of 50% Group 1 and 50% Group 2 @10,000 fish/group

Scenario		Group 1			Group 2				
S_1	p_1	S_1	p_1	λ	S_1	p_1	λ	$E(\hat{S})$	$\hat{\hat{S}}$
same	same	0.90	0.20	0.18	0.90	0.20	0.18	0.90	0.901
diff	same	0.90	0.20	0.18	0.80	0.20	0.18	0.85	0.851
same	diff	0.90	0.20	0.18	0.90	0.10	0.18	0.90	0.901
diff	diff	0.90	0.20	0.18	0.80	0.10	0.18	0.85	0.851
diff	diff	0.90	0.10	0.18	0.80	0.20	0.18	0.85	0.851

Scenario

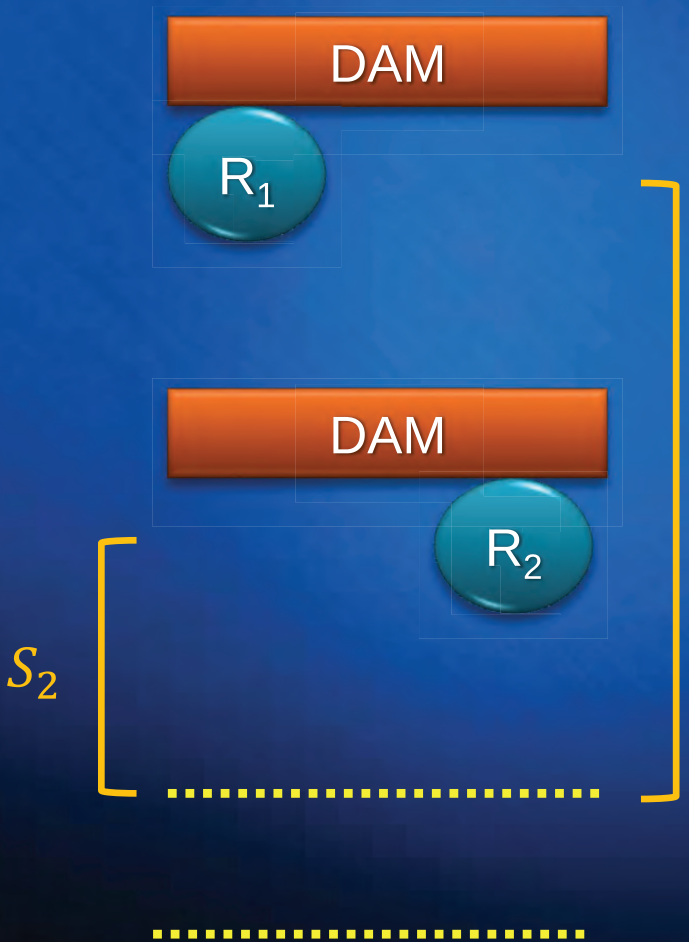


- Model fully robust to unequal survival
- Model quite robust to unequal detection

Assumption #8: Releases share same survival processes in reaches in common

- Concern:
  - Necessary assumption to partition out project survival

$$\hat{S}_{\mathrm{Proj}} = \frac{\hat{S}_1}{\hat{S}_2} \to \frac{S_{\mathrm{Proj}} \cdot \cancel{S_2}}{\cancel{S_2}} = S_{\mathrm{Proj}}$$

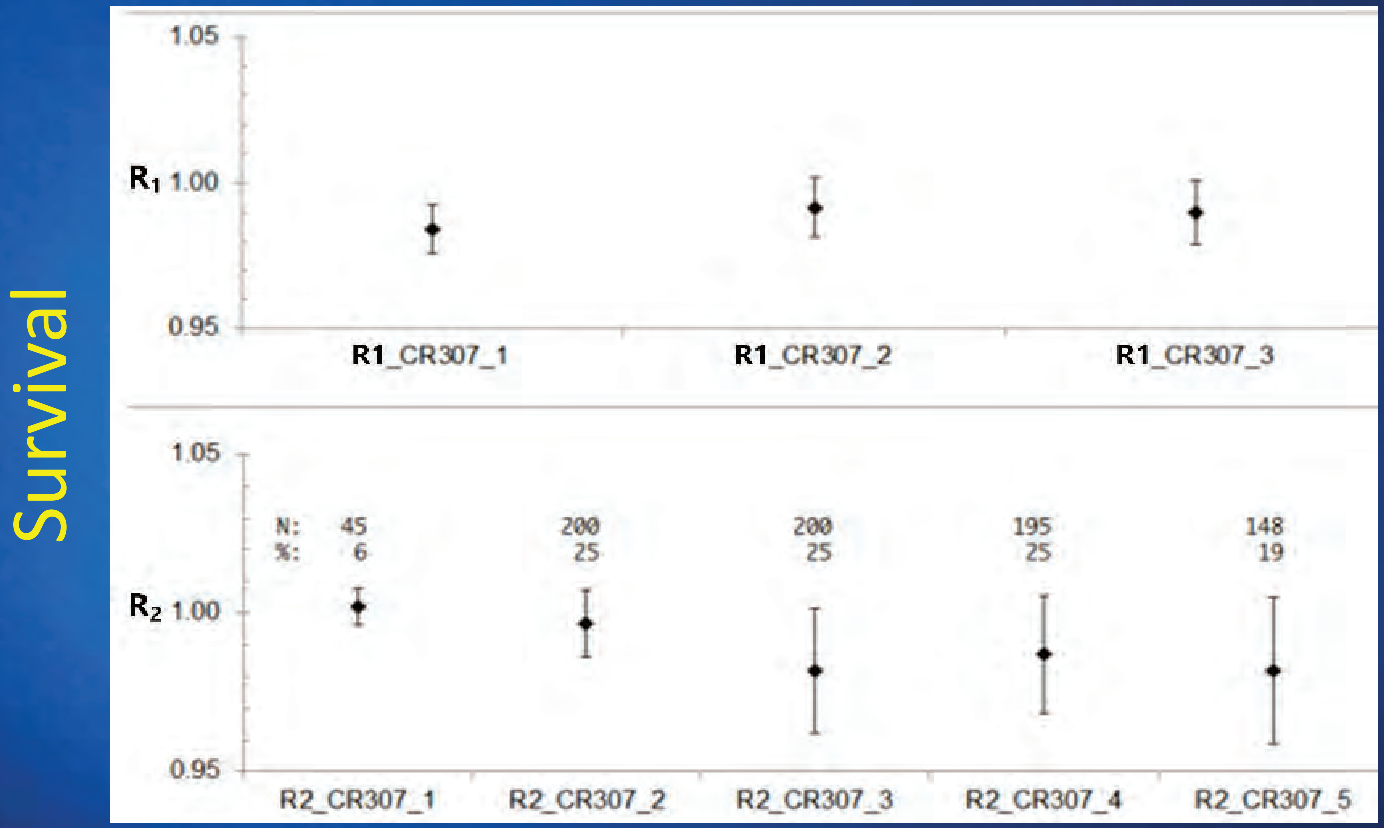


$S_1 = S_{\mathrm{Proj}} \cdot S_2$

- Actions:
  - Stagger release times to facilitate downstream mixing
  - Distribute R_2 releases to mimic R_1 passage

Assumption #8 (continued)

- Examine spatial pattern of R_1 and R_2 survivals
  - E.g., The Dalles Dam, 2012



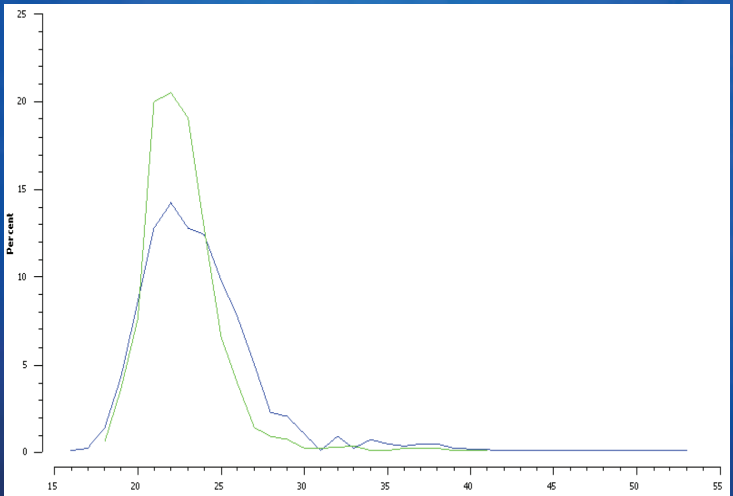
Release site – across river channel

  - Look for mortality "hot spots" at R_2 release locations across river

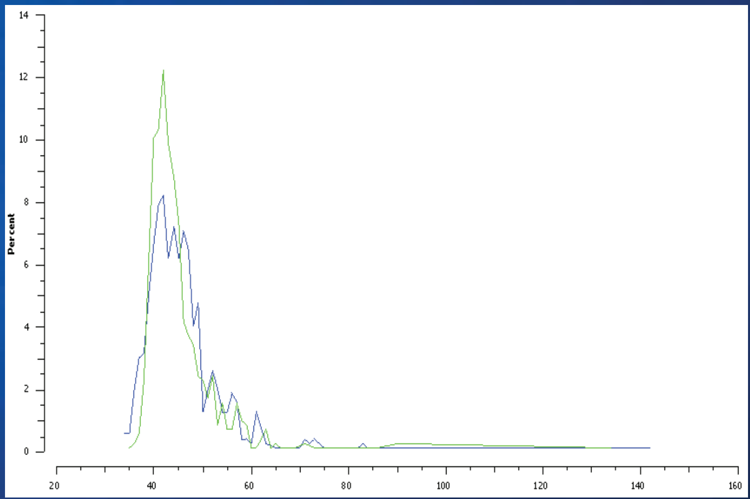
Assumption #8 (continued)

- Examine downstream mixing plots
  - E.g., The Dalles Dam, 2012

Rkm 234



Rkm 156



Arrival Time (Hours)

R_1 R_2

Assumption #9: Fish either migrate downriver or die

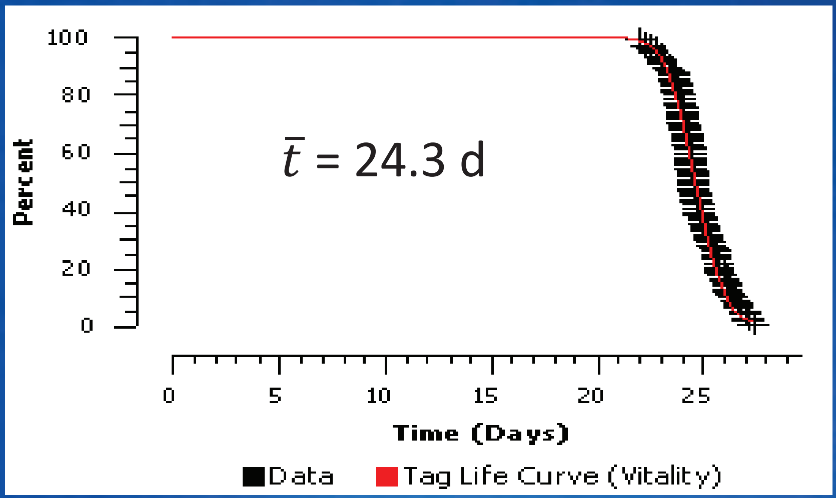
- Concerns:
  - The CJS model estimates "perceived survival," the joint probability of a fish migrating and surviving through a reach
  - $\hat{S}_{\text{Project}}$ will be biased if residualization occurs
- Actions:
  - Use only active migrants
    - Collected in bypass system
    - Conduct studies before high water temperatures
  - Obtain residualization-corrected survival estimates
    - Augmented acoustic-tag study design
    - PIT-tag study design generally incapable of estimating residualization
    - Nevertheless, problem is interpretation

Assumption #10: No tag failure

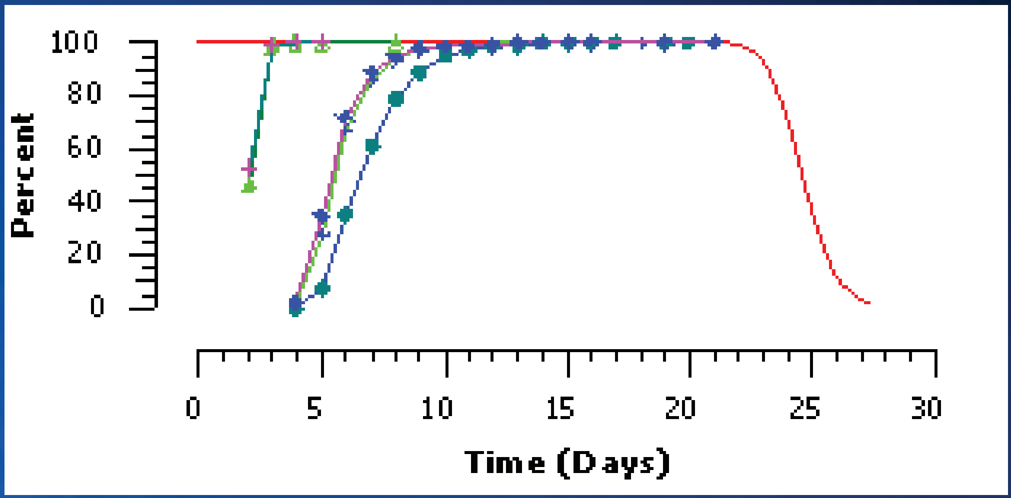
- Concerns:
  - The CJS model estimates the joint probability of the fish and the tag being "alive"
  - Premature tag failure will negatively bias survival estimates
- Actions:
  - Conduct tag-life studies
  - Use Program ATLAS to provide tag-life-adjusted survival estimates

Assumption #10 (continued)

Estimation of tag-life curve



Assure tag life adequate for study



E.g., John Day Dam, 2014

Assumption #10 (continued)

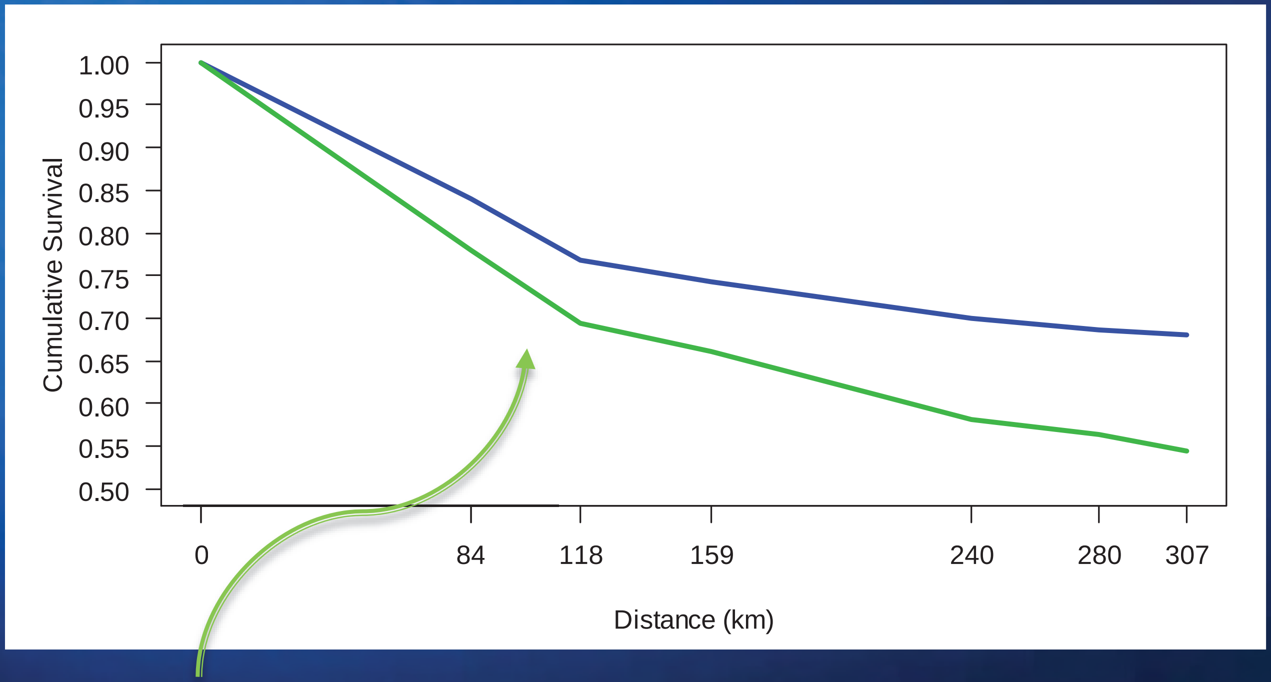
- Tag-life study recommendations:
  - Separate tag-life study for each unique tag lot
  - Monitor tags continuously from onset to complete tag failure
  - Monitor in ambient water (i.e., battery life function of temperature)
  - Sample size: $50 \leq n \leq 100$ per tag lot

Assumption #11: No handling or tag effects that could distort survival studies

- Concerns:
  - Tagger effects could occur
  - Tag-burden effects could exist
  - Both tagger and tag-burden effects are time dependent and can bias $\hat{S}_{\text{Project}}$ downward
- Actions:
  - Rigorous surgeon training, testing, and in-season monitoring
    - Eliminate releases by bad taggers
  - Balance tagger effort across releases
  - Need multiple taggers to identify a problem

Assumption #11 (continued)

- Tagger effects are time and distance dependent
  - R_1 release will be affected more than R_2 release
  - Negatively bias $\hat{S}_{\text{Project}}$



The further the distance traveled, the worse the survival

Assumption #11 (continued)

- Balance tagger effort across releases to minimize any undetected effects

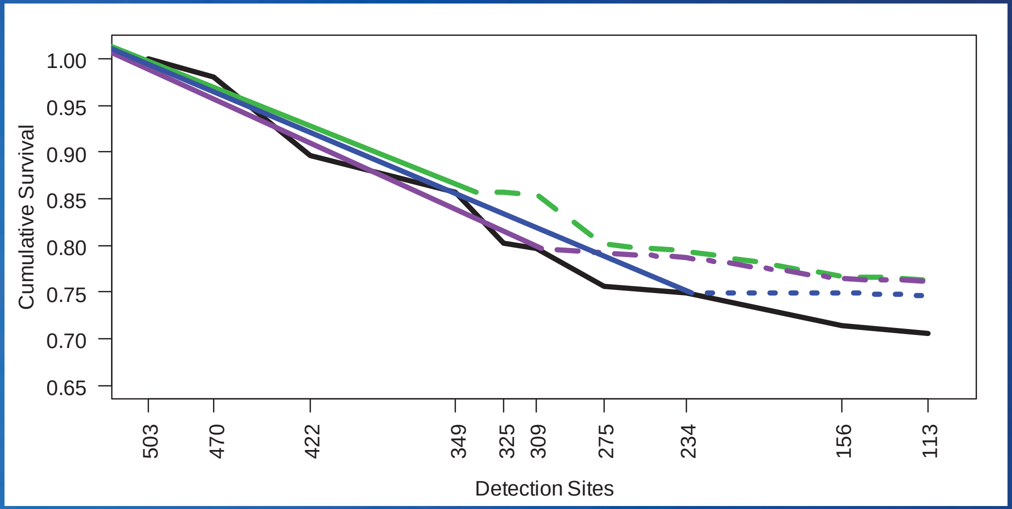
	Tagger		
	A	B	C
R_1	20%	40%	30%
R_2	20%	40%	30%

- Also balance tagger effort across season

	Week			
Tagger	1	2	3	4
A	20%	20%	20%	20%
B	40%	40%	40%	40%
C	30%	30%	30%	30%

Assumption #11 (continued)

- Tag burden effect
  - E.g., McNary, John Day, The Dalles, Bonneville 2012



Found tag burden effect for subyearlings that migrated through 4 projects but not for subyearlings that migrated through ≤3 projects

II. Estimating Residualization in Subyearling Studies

A. Single Release

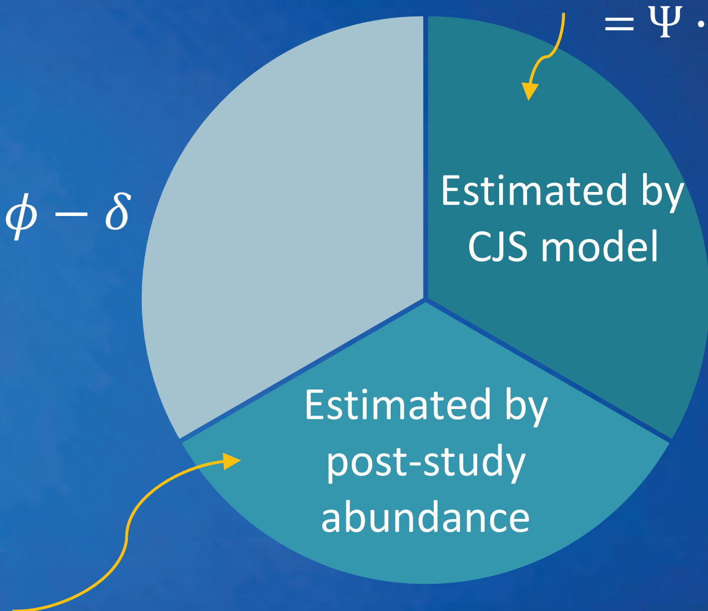
B. Paired Release

A. Single Release

- Partitioning the fate of subyearlings

$\phi = \text{Prob (migrating \& surviving)}$
$= \Psi \cdot S_{\text{MIG}}$

Prob (death) $= 1 - \phi - \delta$



$\delta = \text{Prob(residualizing \& surviving)}$
$= (1 - \Psi) \cdot S_{\text{RES}}$

Overall survival: $S = \phi + \delta$

$$= (\Psi) S_{\text{MIG}} + (1 - \Psi) S_{\text{RES}}$$

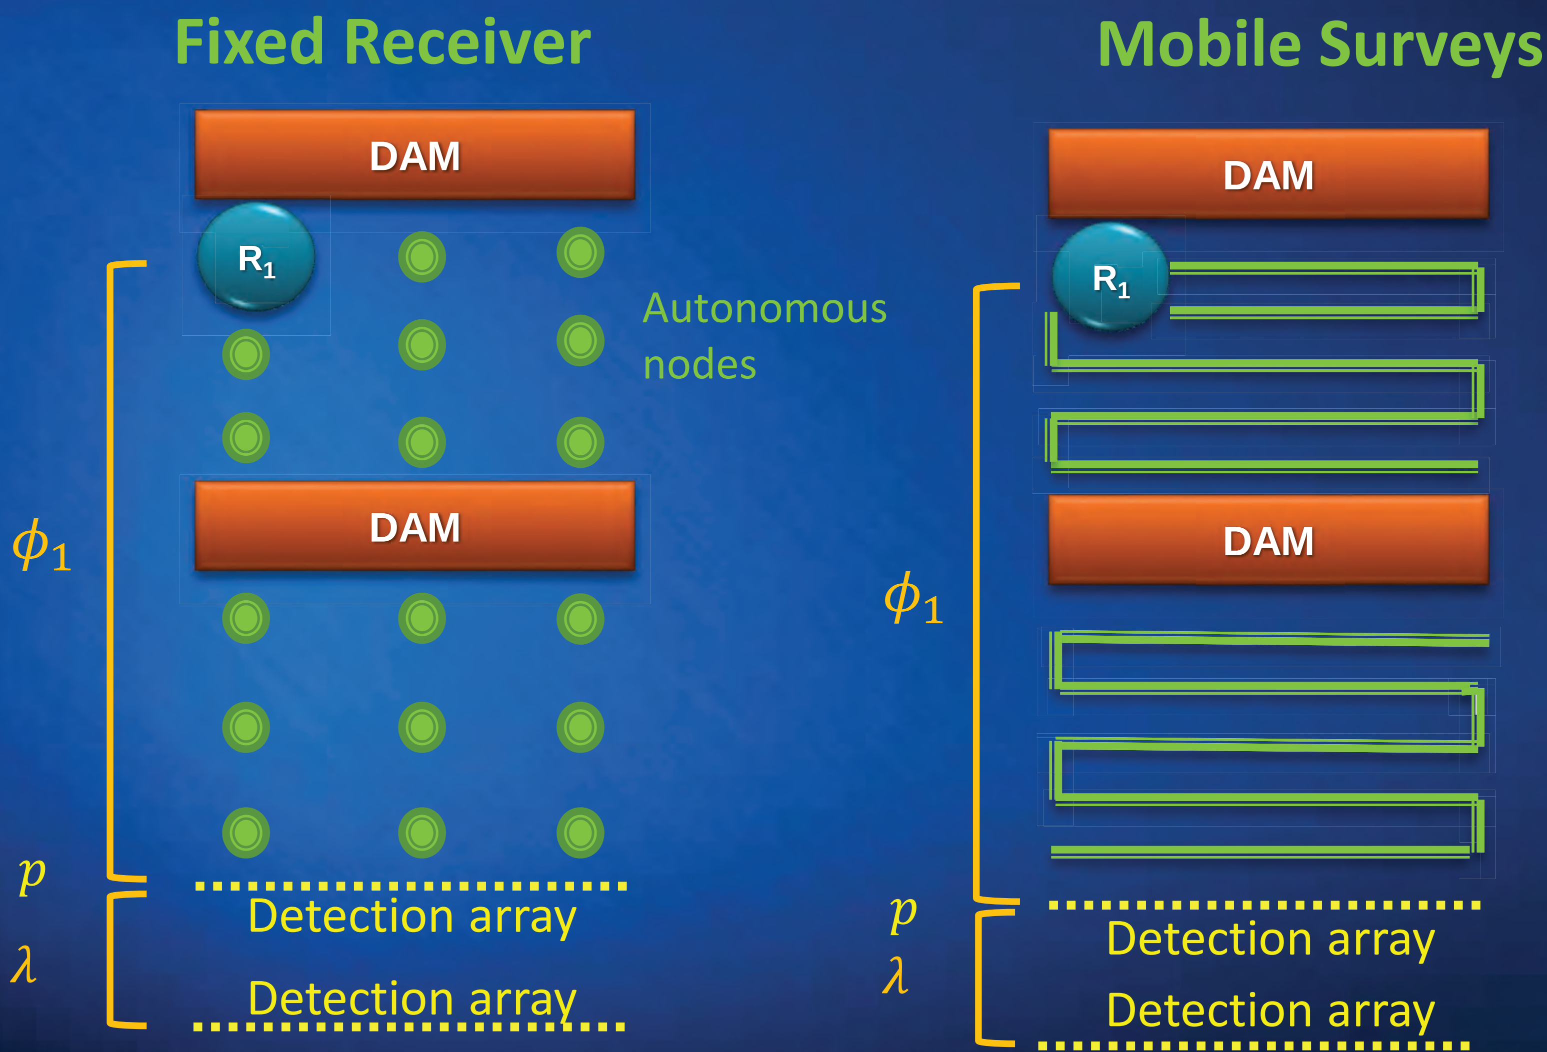
Partitioning Fate (continued)

- Joint probability of migrating and surviving estimable
$$\phi = \Psi \cdot S_{\mathrm{MIG}}$$
- Joint probability of <u>not</u> migrating and surviving estimable
$$\delta = (1 - \Psi) \cdot S_{\mathrm{RES}}$$
- Overall survival estimable
$$S = \Psi \cdot S_{\mathrm{MIG}} + (1 - \Psi) S_{\mathrm{RES}}$$
- Note separate estimates of $\hat{S}_{\mathrm{MIG}}$, $\hat{S}_{\mathrm{RES}}$, and $\widehat{\Psi}$ are not available

Estimating Residualization

$$\hat{\delta} = \frac{\hat{N}}{R_1}$$

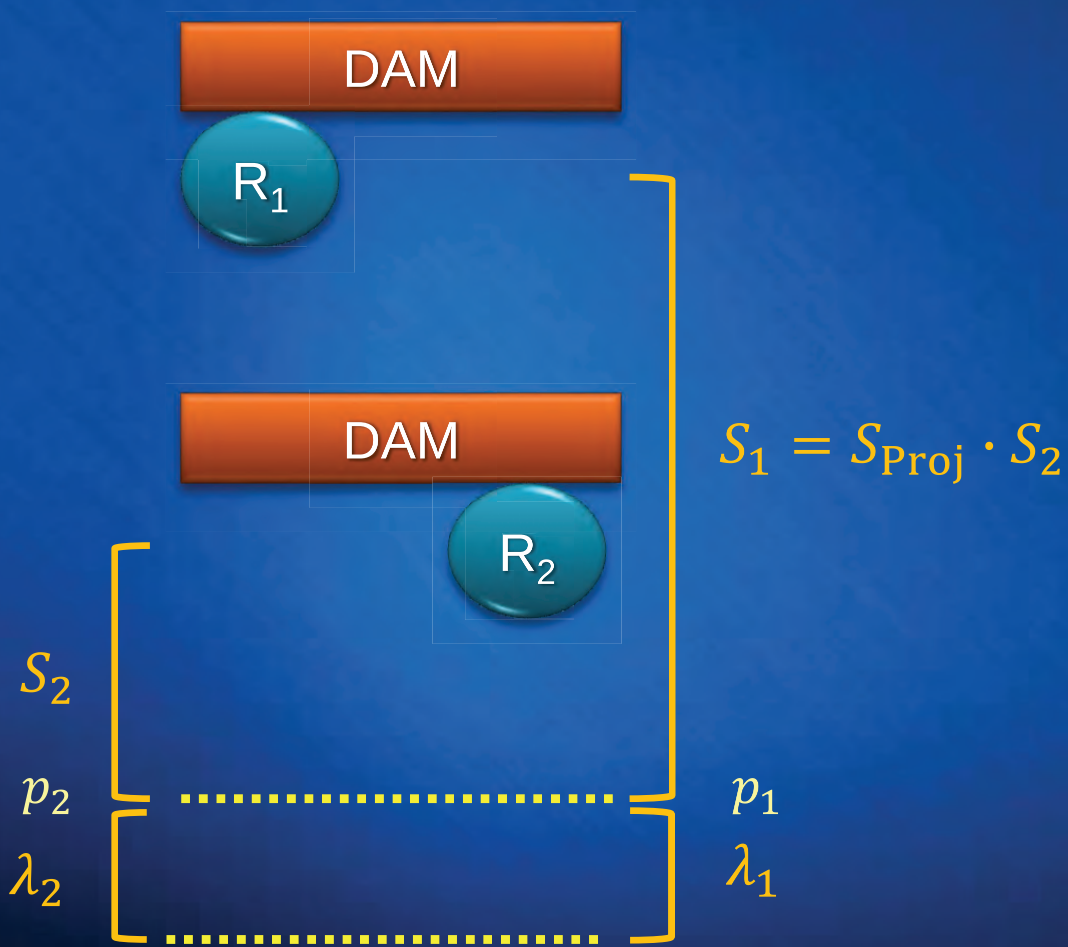
- Augmented designs to estimate residualization



- Must conduct minimum of two surveys to estimated residualized fish abundance just prior to end of study, δ

B. Paired Release

- Statistical model – No residualization



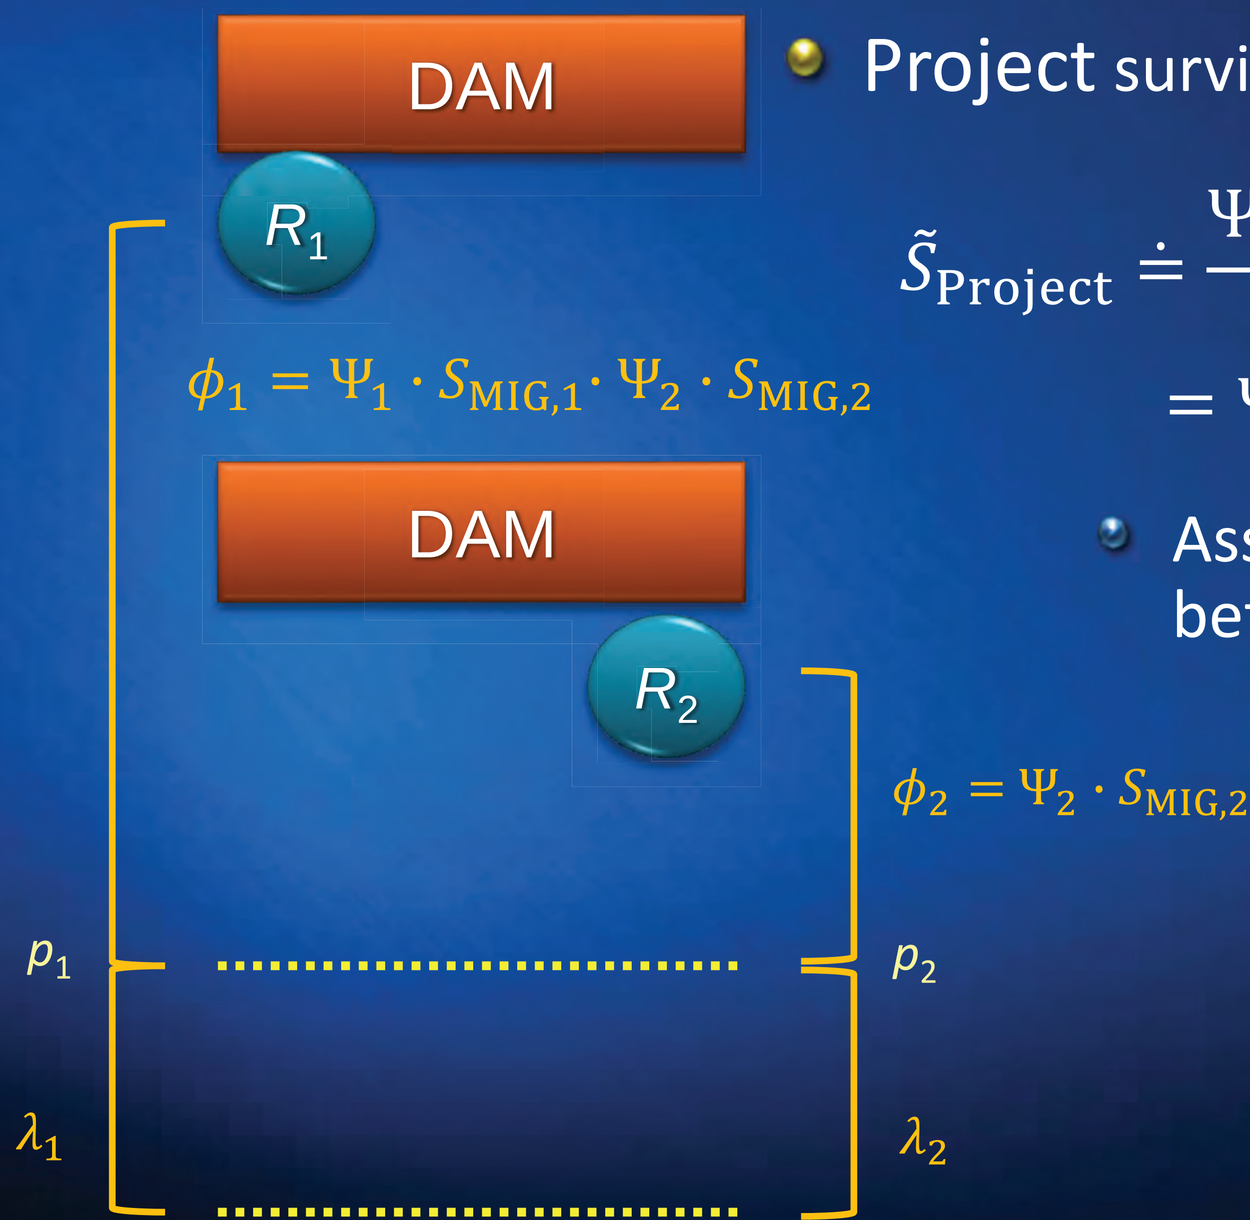
- Project passage survival estimated by

$$\hat{S}_{\text{Project}} = \frac{\hat{S}_1}{\hat{S}_2}$$

where

$$E\left(\hat{S}_{\text{Proj}}\right) \doteq \frac{S_{\text{Proj}} \cdot \cancel{S_2}}{\cancel{S_2}} = S_{\text{Proj}}$$

Paired Release with Residualization



- Project survival

$$\tilde{S}_{\text{Project}} \doteq \frac{\Psi_1 S_{\text{MIG},1} \cdot \Psi_2 S_{\text{MIG},2}}{\Psi_2 S_{\text{MIG},2}}$$

$$= \Psi_1 S_{\text{MIG},1}$$

  - Assumes common Ψ_2 between releases

Paired Release with Residualization (continued)

- Under ideal conditions/assumptions, can estimate only the joint probability of migrating and surviving through project ($\Psi_1 S_{\text{MIG},1}$)
- Model assumptions may be unrealistic
  - Both releases must have same residualization probability in the second reach
- Basing assessment on ratio of total survivals:

$$\frac{\hat{S}_{\text{Total},1}}{\hat{S}_{\text{Total},2}} = \frac{\hat{\phi}_1 + \hat{\delta}_1}{\hat{\phi}_2 + \hat{\delta}_2}$$

  - Very convoluted interpretation and not useful approach

Ratio of Total Survival Estimates

$$\frac{\phi_1 + \delta_1}{\phi_2 + \delta_2} = \frac{\Psi_1 S_{\mathrm{MIG},1}\left(\Psi_2 S_{\mathrm{MIG},2} + (1-\Psi_2) S_{\mathrm{RES},2}\right) + (1-\Psi_1) S_{\mathrm{RES},1}}{\left(\Psi_2 S_{\mathrm{MIG},2} + (1-\Psi_2) S_{\mathrm{RES},2}\right)}$$

No useful simplification or interpretation

Residualization and Paired Releases

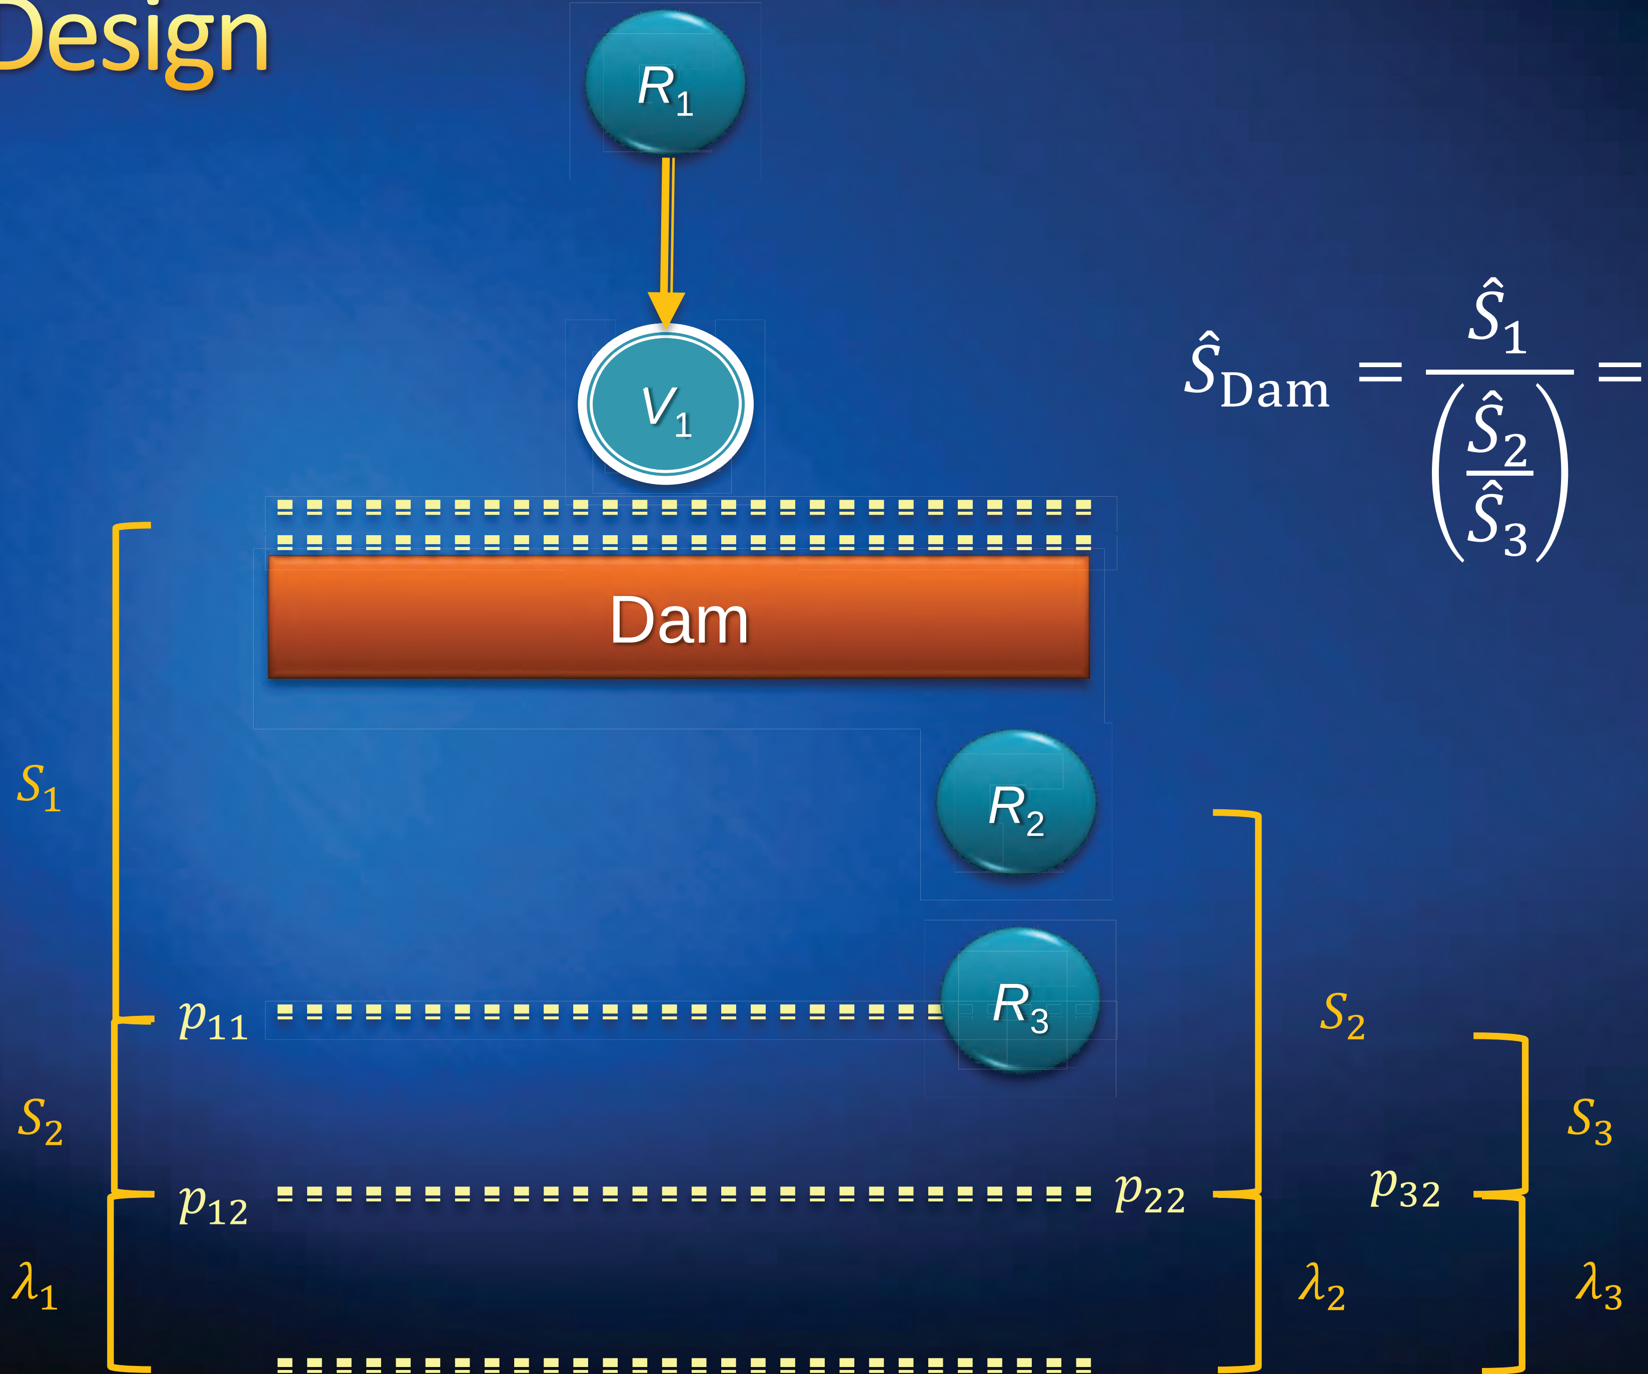
- Estimating total survival not helpful
- Use CJS model to estimate ΨS
- Use active migrants (i.e., $\Psi = 1$)
  - Allows direct estimation of S
- Use in-reservoir surveys to confirm assumption of no residualization

III. Overview of USACE Subyearling Studies

Survival Requirements in FCRPS

- Estimate dam passage survival defined as survival from dam face to tailrace mixing zone
- Survival standards
  - Yearling Chinook salmon and steelhead: $\hat{S} \geq 0.96$
  - Subyearling Chinook salmon: $\hat{S} \geq 0.93$
- Precision standard
  - $\widehat{\mathrm{SE}}\left(\hat{S}\right) \leq 0.015$
- Two consecutive successful trials per fish stock
- Hydraulic conditions
  - Representative
  - Diverse

Overview of the Virtual/Paired-Release Design



$$\hat{S}_{\text{Dam}} = \frac{\hat{S}_1}{\left(\frac{\hat{S}_2}{\hat{S}_3}\right)} = \frac{\hat{S}_1 \cdot \hat{S}_3}{\hat{S}_2}$$

Estimates of Dam Passage Survival of Subyearling Chinook Salmon

Dam	Year	$\hat{\hat{S}}$
Bonneville	2012	0.9739 (0.0069)
John Day	2012	0.9414 (0.0031)
	2014	0.9169 (0.0061)
The Dalles	2010	0.9404 (0.0091)
	2012	0.9469 (0.0059)
McNary	2012	0.9747 (0.0114)
	2014	0.9239 (0.0180)
Lower Monumental	2012	**0.9789 (0.0079)**
	2013	0.9297 (0.0105)
Little Goose	2012	0.9508 (0.0097)
	2013	**0.9076 (0.0139)**
Lower Granite	2018	0.9422 (0.0217)
		$\hat{\hat{S}}$ = 0.9439

USACE – Acoustic-tag Studies ----Tag weights (in air): 0.430 g (2010), 0.304-0.346 g (2012-14), 0.216 g (2018)

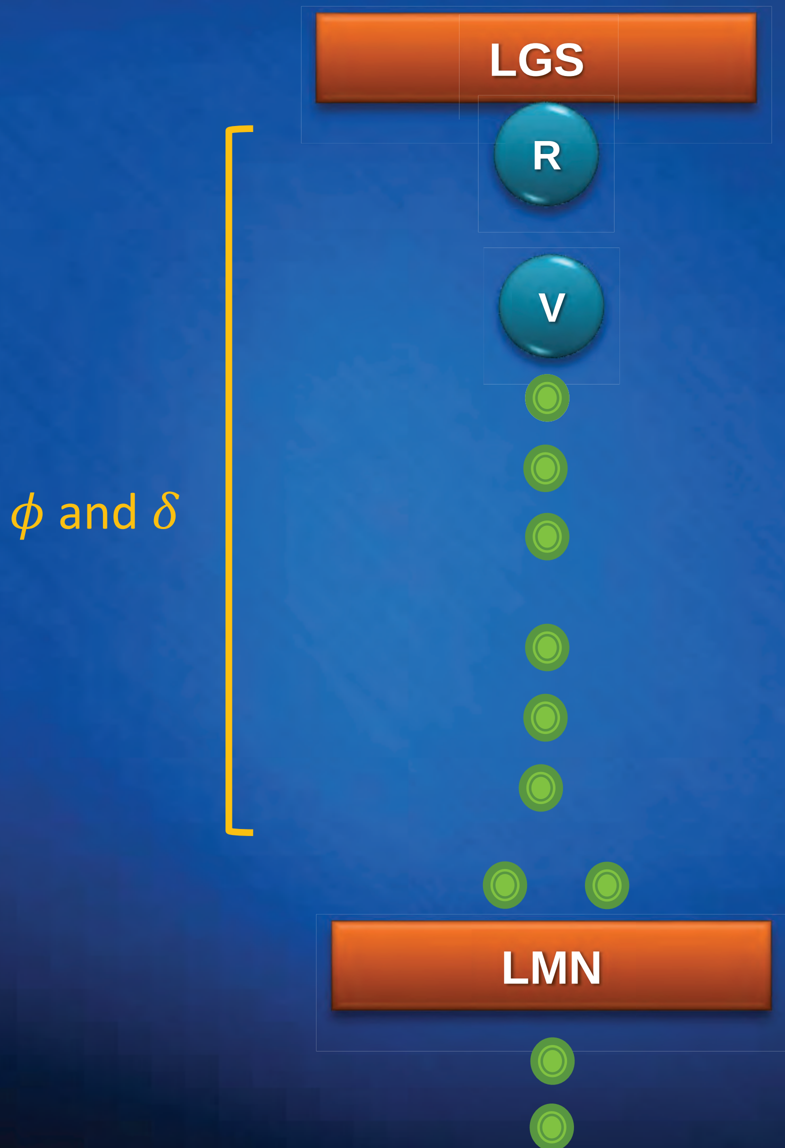
	Lower Monumental	SR112, 065	0.8723 (0.0107)	
			$\hat{\bar{S}} = 0.8595$	

*Only a fraction of reservoir incorporated

IV. Example: Lower Monumental 2007 Subyearling Acoustic-Tag Study

- Objectives:
  - Estimate subyearling Chinook salmon survival in the LMN pool
  - Determine extent of residualization
  - Characterize residualization pattern over season

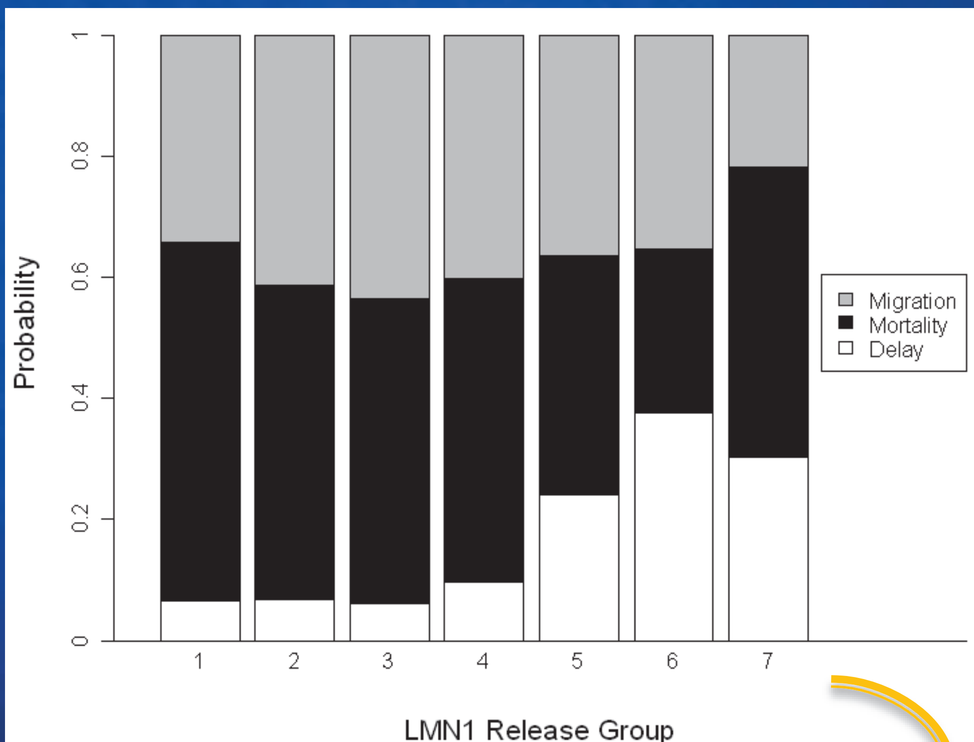
Release–Recapture Design



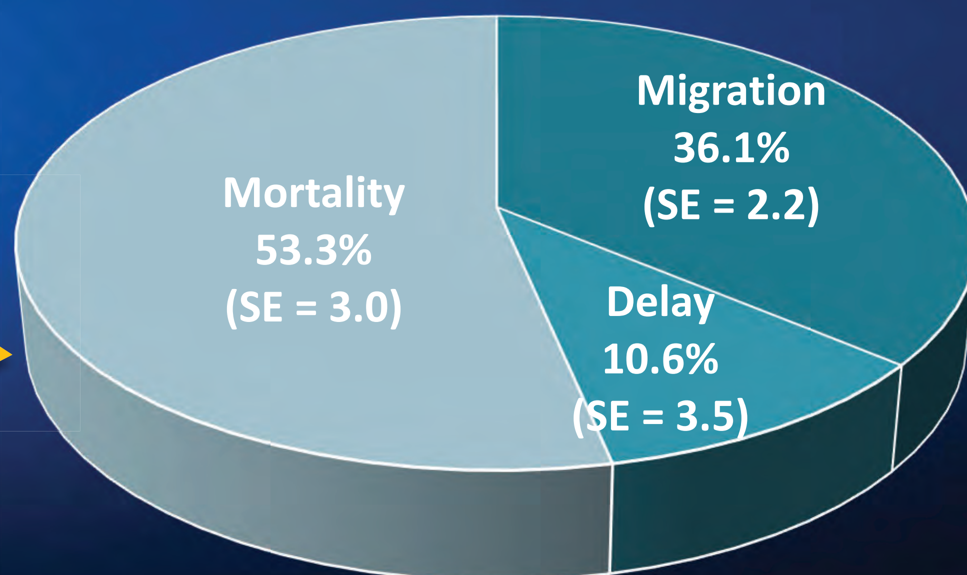
- 7 weekly virtual release groups, 1 August – 19 Sept, 2007
- 8-week sampling period for each release group
- Residualization surveys occurred last 2 days of sampling periods
  - Lincoln Index estimate of residualized fish abundance

Pooling Fate Across Release Groups

Release-Specific Reservoir Fates



Study-Wide Result



V. Subyearling Chinook Salmon PIT-Tag Survival Results

Example: PIT-tagged Subyearlings

Priest Rapids Hatchery to McNary

- Joint probability of migration and survival: ϕ

Year	$\hat{S}$	$SE(\hat{S})$
2013	0.668	0.023
2014	0.626	0.015
2015	0.783	0.049
2016	**0.847**	0.039
2017	0.532	0.018
2018	0.521	0.024

Year	$\hat{S}$	$SE(\hat{S})$
2000	0.676	0.046
2001	0.748	0.025
2002	0.695	0.036
2003	0.632	0.022
2004	**0.460**	0.024
2005	0.652	0.038
2006	0.680	0.049
2007	0.690	0.063
2008	0.702	0.080
2009	0.622	0.057
2010	0.614	0.061
2011	0.804	0.124
2012	0.612	0.020

$$\hat{\hat{S}} = 0.661$$

Example: PIT-Tagged Subyearlings

$\sqrt[4]{S}$ - Lyons Ferry Hatchery: Lower Granite to McNary

Year	$\hat{S}$	$SE(\hat{S})$
2006	0.917	0.0012
2008	0.947	0.006
2009	0.922	0.005
2010	0.970	0.007
2011	**0.981**	0.005
2012	0.928	0.025
2013	0.912	0.016
2014	0.934	0.022
2015	0.849	0.035
2016	**0.845**	0.017
2017	0.857	0.016
2018	0.911	0.016
	$\hat{\hat{S}}$ = 0.914	

VI. Subyearling Study Design Recommendations

Recommendations

- Desirable parameter S_{MIG} not separately estimable
- What is estimable:
  - $\phi = \Psi \cdot S_{\mathrm{MIG}}$ = joint probability of migration and survival

  or

  - $\phi + \delta$ = total survival, which is time dependent
- Paired release can only estimate ϕ under perhaps unrealistic assumptions
- Therefore, statistical solution to subyearling residualization may not exist

Recommendations (continued)

- Instead, use active migrants during early summer when water temperatures are acceptable (i.e., <18°C)
- Use paired-release design
- Minimum of 2 downstream detection sites
  - >2 are required to test assumptions
- Detection sites far enough downriver to allow both releases to express post-release handing effects
- Multiple well-trained surgeons
  - Balance effort temporally and spatially
- Tag-life study, $n \geq 50$ per tag lot

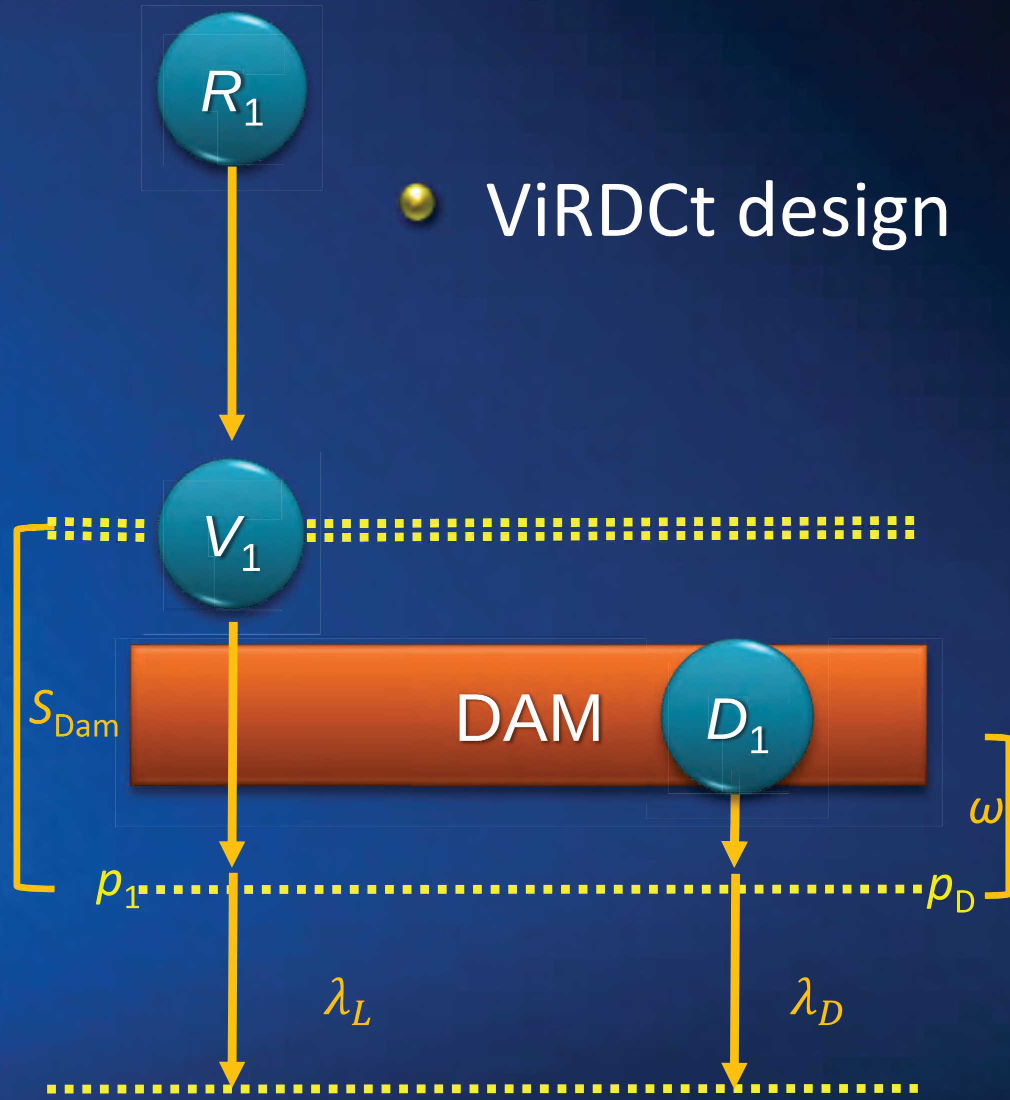
Recommendations (continued)

- Use within-reservoir surveys to ensure residualization rates are minimal
  - Mobile or fixed location
  - If mobile, repeat 2–3 times at end of study before tag life becomes a problem
  - Tag-life long enough to allow active migrants to exit study and still detect residualized fish
- PIT-tag studies incapable of estimating residualization between dams
- Expect project survival estimates to be lower than yearling Chinook salmon and steelhead
  - Fish size
  - Residualization
- Adjust release sizes for lower anticipated survival estimates

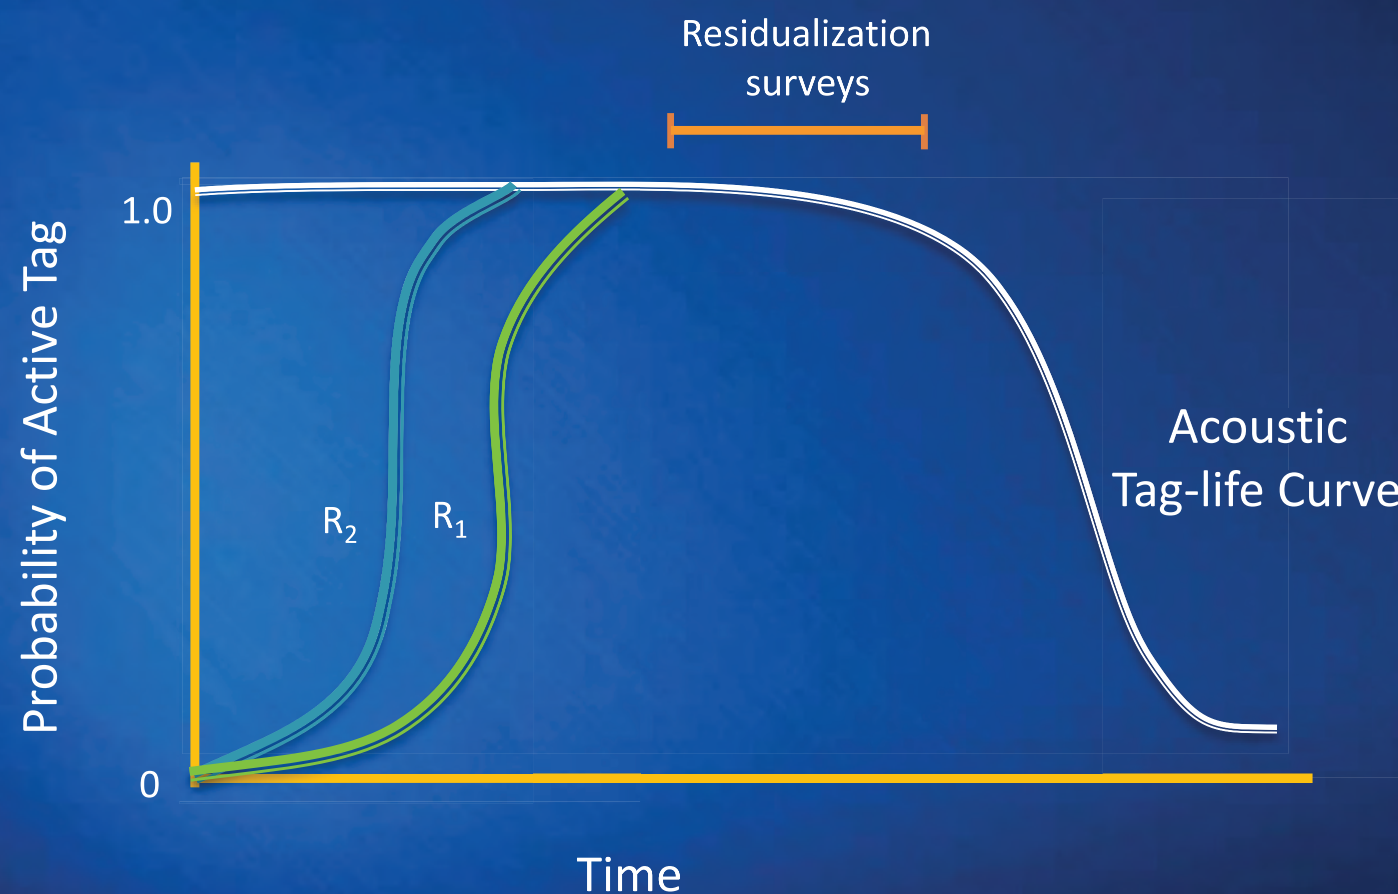
Recommendations (continued)

- Alternative: Estimate dam passage survival
- Paradigm shift: dam passage survival vs project survival
- Pros:
  - Robust to residualization (assume no residualization during dam passage)
  - Existing methods: Virtual Release/Dead Fish Correction (ViRDCt design)
  - Smaller sample sizes than for project survival
- Cons:
  - Not applicable to existing criteria
- NMFS: dam passage survival ≥ 0.93 for subyearlings in FCRPS

- ViRDCt design



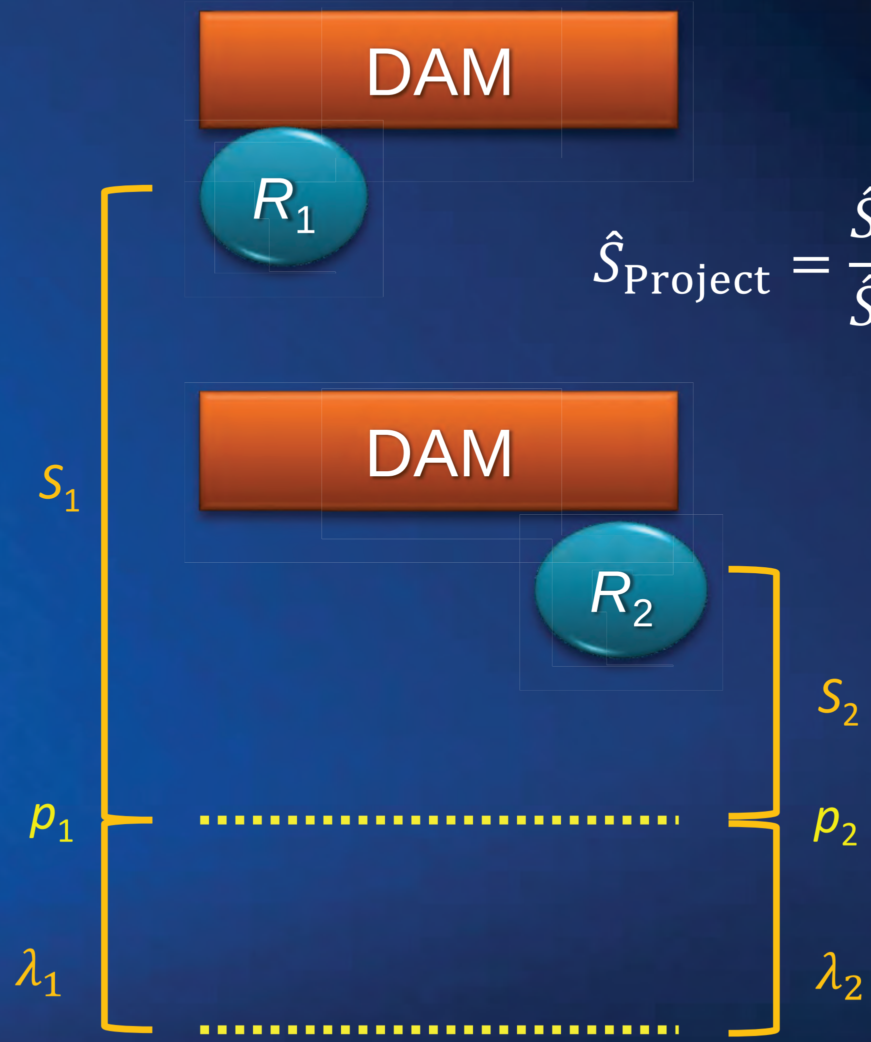
Idealized Study Timing



Idealized Study Spacing

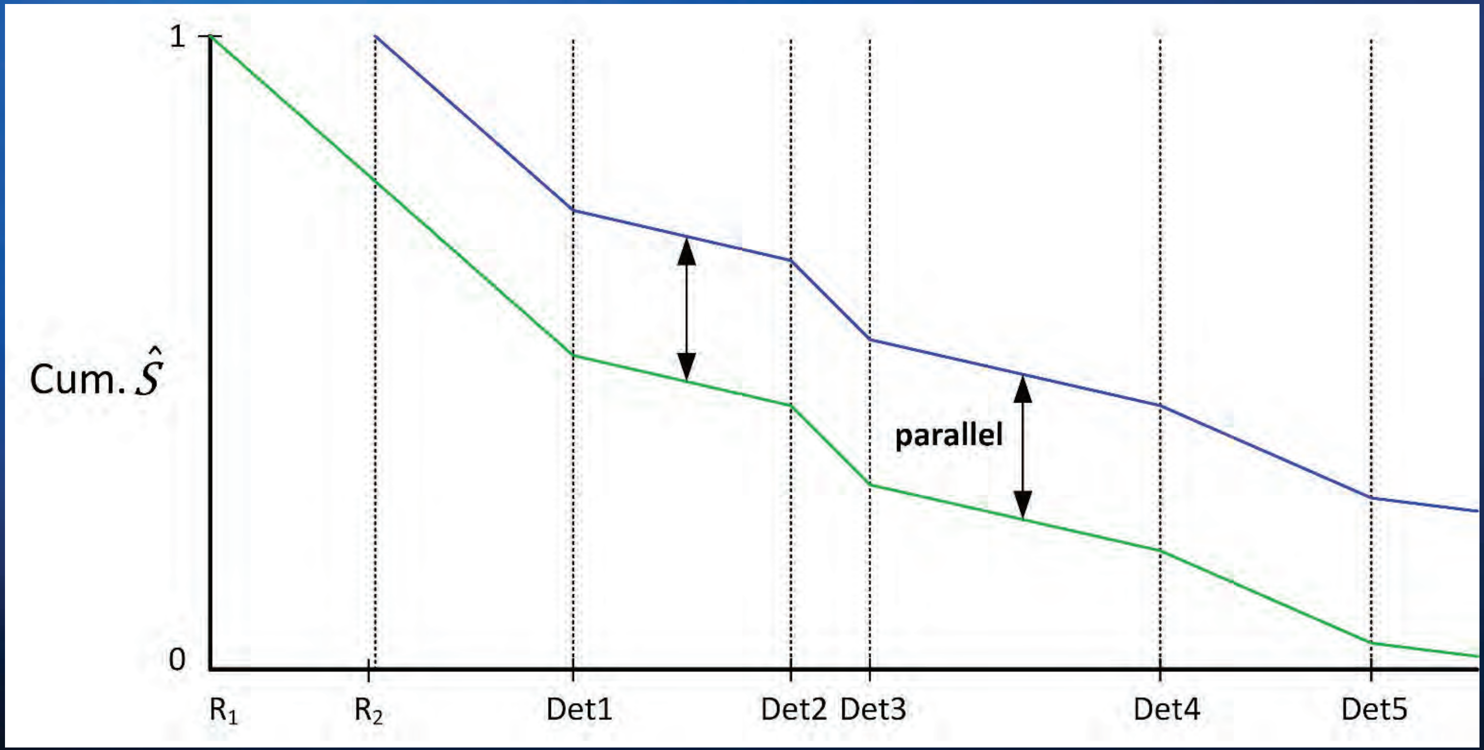
- If reach 1 is too long
  - "Backpack effect": increasing expression of tag burden effect
- If reach 2 is too short
  - False positive detections (mortalities from dam passage)
  - Unequal expression of handling effects
- Tag burden, unequal handling effects → $\hat{S}_{\text{Proj}}$ is negatively biased
- False positive detections → $\hat{S}_{\text{Proj}}$ is positively biased

$$\hat{S}_{\text{Project}} = \frac{\hat{S}_1}{\hat{S}_2}$$

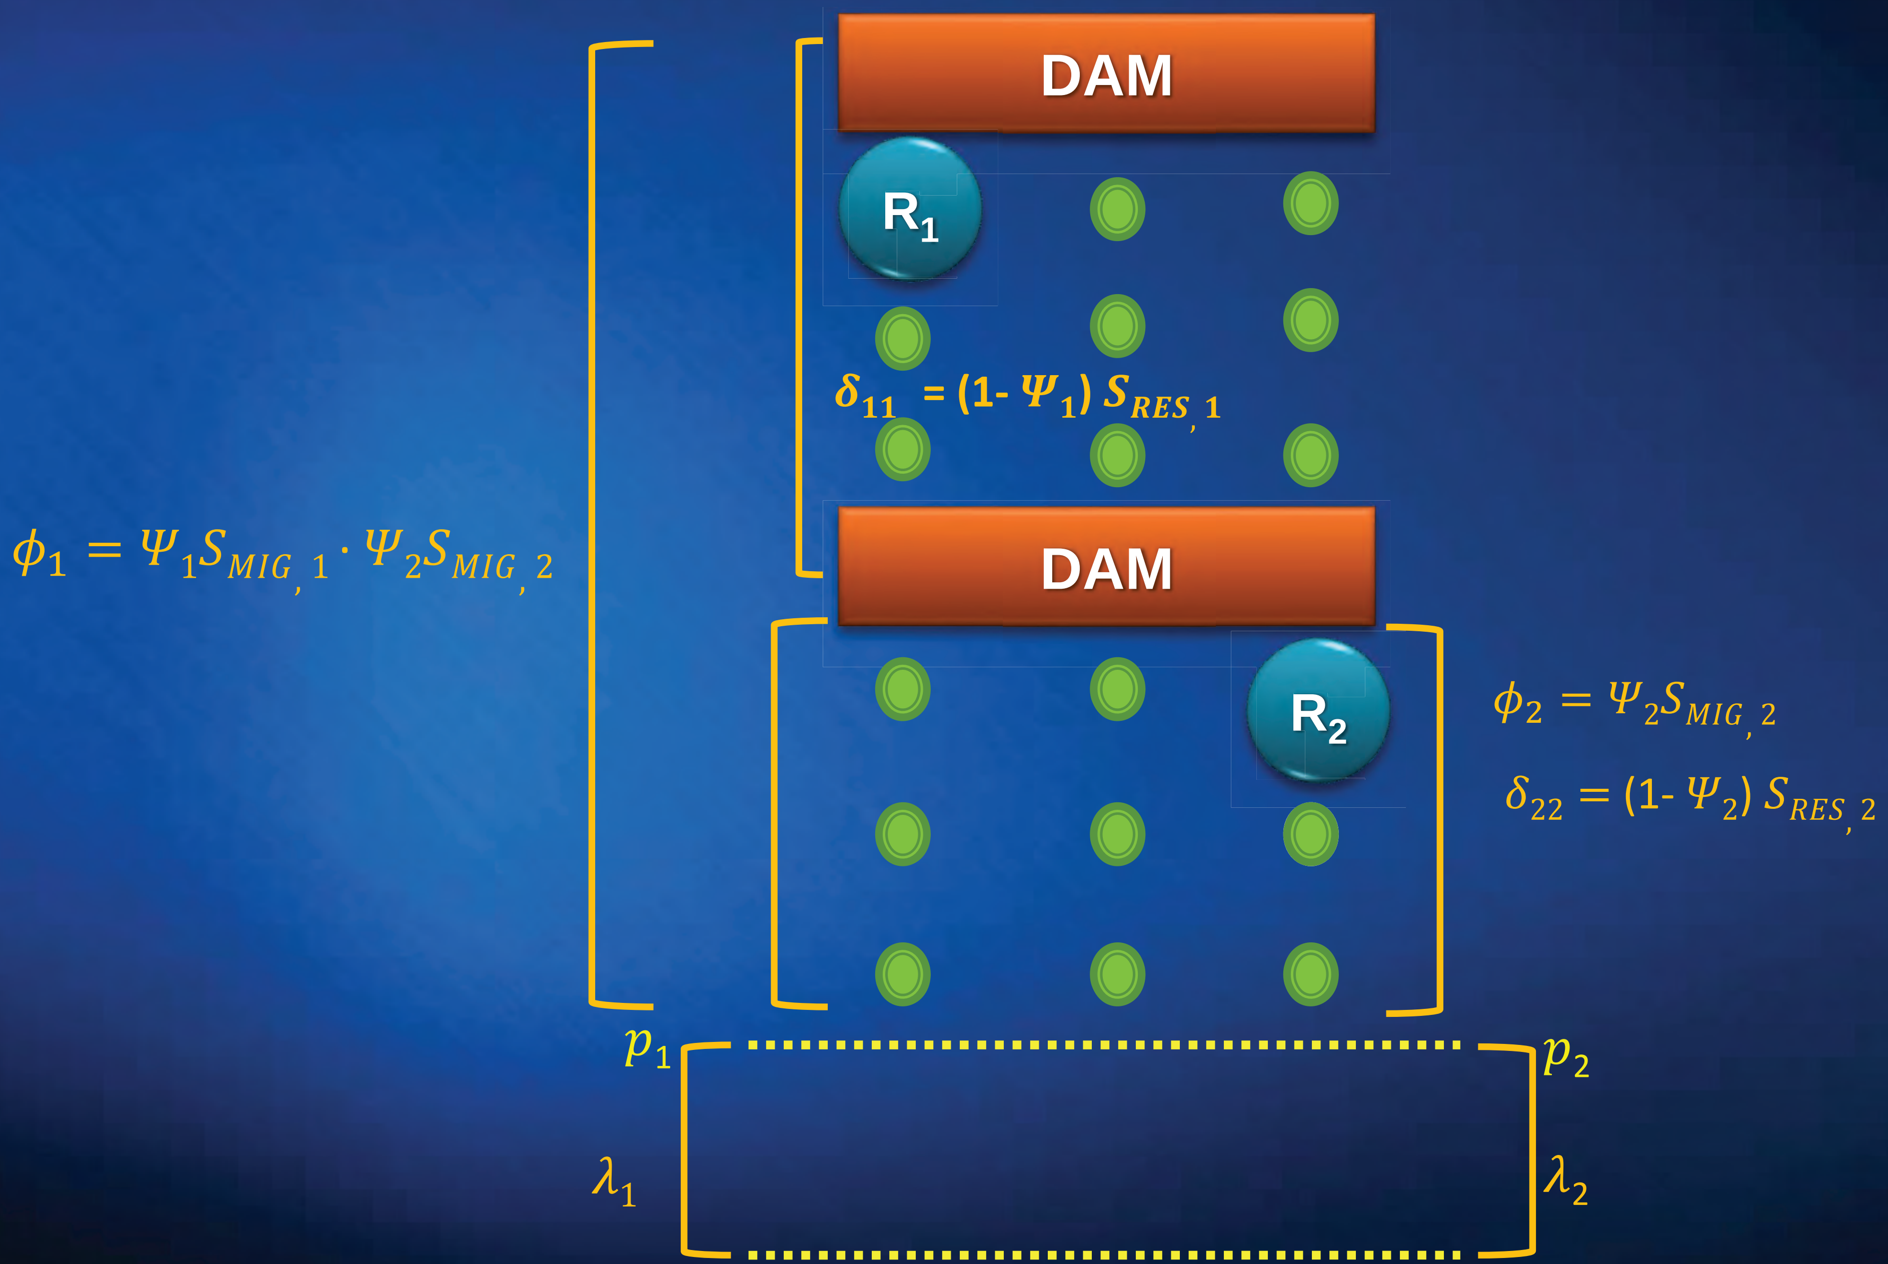


Idealized Study Spacing (continued)

- Negative bias in project survival: not bad if meet standard
- Diagnosis of tag burden effects
  - Compare cumulative survival from paired releases
  - Identify departure from parallel curves



Residualization



Residualization (Continued): Options

1. Use active migrants: $\Psi_1 \approx 1, \Psi_2 \approx 1$

2. Use ratio of release-specific CJS estimates (if common Ψ_2):

$$\frac{\hat{\phi}_1}{\hat{\phi}_2} \approx \frac{\Psi_1 S_{MIG,1} \cancel{\Psi_2 S_{MIG,2}}}{\cancel{\Psi_2 S_{MIG,2}}} = \Psi_1 S_{MIG,1}$$

3. Estimate total survival:

$$\frac{\hat{\phi}_1}{\hat{\phi}_2} + \hat{\delta}_{11} \approx \Psi_1 \, S_{MIG,1} + (1 - \Psi_1) S_{RES,1}$$

4. Paradigm shift → dam passage survival

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: September 24, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the August 27, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, August 27, 2019, from 10:00 a.m. to 12:45 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item I-C).
- Douglas PUD will review available passive integrated transponder (PIT)-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item I-C).
- Kirk Truscott will submit Colville Confederated Tribes (CCT) comments on the *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* to Tom Kahler (Item I-C).
- Lance Keller will update Keely Murdoch on subyearling discussions to date, including Chelan PUD's plan to request approval of a renewed Statement of Agreement (SOA) during the HCP Coordinating Committees meeting on September 24, 2019, that maintains subyearling Chinook salmon in Phase III (Additional Juvenile Studies) for the Rock Island and Rocky Reach projects for up to 3 years (Item III-B). *(Note: Keller discussed this topic with Murdoch, as described in an email distributed to the HCP Coordinating Committees by Kristi Geris on September 3, 2019.)*
- Lance Keller will distribute to the HCP Coordinating Committees a draft SOA, maintaining subyearling Chinook salmon in the Rock Island and Rocky Reach projects in Phase III (Additional Juvenile Studies) for up to 3 years, for vote during the HCP Coordinating Committees meeting on September 24, 2019 (Item III-B). *(Note: Keller provided a draft SOA to Kristi Geris on September 19, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Lance Keller will distribute to the HCP Coordinating Committees results from the Rocky Reach Dam Turbine Unit C3 Chesterton seal tests once they become available (Item IV-A). *(Note:*

Keller provided an update on the Chesterton seal tests to Kristi Geris on September 19, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)

- Lance Keller will explain to Keely Murdoch Chelan PUD's request to begin the 2019/2020 annual ladder maintenance work period at Rocky Reach Dam on December 16, 2019, which is 2.5 weeks earlier than usual, to allow more time to complete required work, and request that Murdoch provide the Yakama Nation's (YN's) approval of the request to the Rocky Reach HCP Coordinating Committee via email (Item IV-D). *(Note: Keller discussed this topic with Murdoch and the YN agreed to Chelan PUD's request, as described in an email distributed to the HCP Coordinating Committees by Kristi Geris on September 3, 2019.)*
- The HCP Coordinating Committees meeting on September 24, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item VI-A).

Decision Summary

- There were no HCP Decision Items approved during today's meeting.

Agreements

- Rocky Reach HCP Coordinating Committee representatives present agreed to Chelan PUD's request to begin the 2019/2020 ladder maintenance outage at Rocky Reach Dam 2.5 weeks earlier than usual to allow more time to complete required work, contingent on approval by the YN. Rather than beginning work during the first week in January (per usual), maintenance work will begin on December 16, 2019 (Item IV-D). *(Note: Keely Murdoch provided the YN's agreement to Chelan PUD's request via email on September 3, 2019, as distributed to the HCP Coordinating Committees by Kristi Geris that same day.)*

Review Items

- The *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019.
- The *Northern Pikeminnow Predator Control Program, Rocky Reach and Rock Island Hydroelectric Projects, Draft Summary Report, 2018* was distributed to the HCP Coordinating Committees by Kristi Geris on September 10, 2019 and is available for a 30-day review with edits and comments due to Lance Keller by October 10, 2019.
- A draft SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to three years* was distributed to the HCP Coordinating Committees by Kristi Geris on September 19, 2019 (Item III-B).

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. No additions or changes were requested from HCP Coordinating Committees members. Ferguson added an update on the HCP Policy Committees draft July 9, 2019 meeting minutes.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft July 23, 2019 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. Geris said Dr. Rebecca Buchanan (University of Washington [UW], Columbia Basin Research) also reviewed and commented on the draft minutes. Lance Keller requested one additional edit under the subyearling presentation discussion, slide 16, where he commented that from a predator saturation perspective, a lot of run-of-the-river fish are present "in the middle of a juvenile outmigration compared to the beginning and the end." This edit was incorporated, and HCP Coordinating Committees members present approved the July 23, 2019 meeting minutes, as revised.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on July 23, 2019, and follow-up discussions, were as follows. *(Note: Italicized text corresponds to agenda items from the meeting on July 23, 2019):*

- *HCP Coordinating Committees representatives will prepare technical questions and considerations concerning the feasibility of conducting subyearling Chinook salmon studies with the current information and technology available to date, for discussion with Drs. Rebecca Buchanan and John Skalski (UW, Columbia Basin Research) during the HCP Coordinating Committees meeting on August 27, 2019 (Item I-A).*
  This will be discussed during today's meeting.
- *Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item II-C).*
  This will be discussed during today's meeting and will be carried forward.

- *Douglas PUD will review available PIT-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item II-C).*
  Tom Kahler said these data are still under internal review. This action item will be carried forward.
- *Kirk Truscott will submit CCT comments on the Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report to Tom Kahler by Friday, July 26, 2019 (Item V-B).*
  Truscott said this effort is still ongoing and Kahler said it is not critical to finalize this report right away. This action item will be carried forward.

II. HCP Hatchery and Tributary Committees Update

A. HCP Hatchery and Tributary Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on August 8, 2019:

- *Cottonwood Flats Connection Project Presentation:* Chelan County Natural Resources Department provided an update on the status of the Cottonwood Flats Connection project on the Entiat River. The County described three design alternatives for the project. The Rocky Reach HCP Tributary Committee, which funded a portion of this project, supported a 240-cubic feet per second (cfs) connection to the floodplain (i.e., the floodplain will be activated when flows in the Entiat River are at 240 cfs or greater). The Rocky Reach HCP Tributary Committee also recommended the construction of a short “feeder” channel that will direct flows onto the floodplain. The sponsor, engineers, and the landowner are currently evaluating the Committee’s recommendation. Hillman said more information is expected in September when there will hopefully be resolution on a design.
- *Okanagan River Restoration Monitoring Presentation:* The Okanagan Nation Alliance (ONA) presented results from monitoring enhancement actions implemented on the Okanagan River in Canada, some of which were funded by the HCP Tributary Committees. ONA documented increased abundance and distribution of Chinook salmon and rainbow/steelhead; increases in large wood; positive responses in channel morphology, fish habitat, riparian vegetation and wildlife; increases in macroinvertebrate diversity and richness; and a reduction in coverage of macrophytes (especially Eurasian milfoil). In addition, spawning habitat has increased along with egg-to-fry survival rates. Hillman said these positive results suggest the enhancement efforts are working. John Ferguson asked if these results are provided in a report, and Hillman said they are in annual reports.

- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on September 12, 2019.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on August 21, 2019 (*note: joint HCP Hatchery Committees/PRCC Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Relative Reproductive Success Timeline (joint):* Washington Department of Fish and Wildlife (WDFW) provided the HCP Hatchery Committees with a memorandum clarifying the extension of the Wenatchee spring Chinook salmon relative reproductive study. The last year of sampling DNA from natural-origin adult Chinook salmon at Tumwater Dam will be 2023.
- *Egg Treatment Study (joint):* Douglas PUD provided a study plan that will evaluate the effects of salt, hydrogen peroxide, and elemental copper in controlling saprolegnia infection of summer Chinook salmon eggs during incubation at Wells Fish Hatchery. The pilot study will begin this fall.
- *Update Genetics Section of the Hatchery Monitoring and Evaluation (M&E) Plan (joint):* The HCP Hatchery Committees reviewed edits made to the genetics section of the Hatchery M&E Plan. Revisions were made based on recommendations provided by the Genetics Monitoring Panel. Members will finalize and approve the edits during the HCP Hatchery Committees meeting on September 18, 2019.
- *Broodstock Collection Protocols (joint):* The HCP Hatchery Committees are beginning the process of updating the Broodstock Collection Protocols. Over the next few months, the HCP Hatchery Committees will identify any significant changes that need to be made to the protocols and will identify members who will lead the writeup of certain sections of the protocols.
- *National Marine Fisheries Service (NMFS) Consultation (joint):* NMFS is in the process of signing the Steelhead and Summer Chinook Salmon permits. The permits will then go to the permittees for signature.
- *Expanded Wells Summer Chinook Production for the Southern Resident Killer Whale Population (Wells):* WDFW prepared a proposal that will allow extra production of subyearling summer Chinook salmon at Wells Fish Hatchery. The extra production is intended to benefit the Southern Resident Killer Whale population. The Wells HCP Hatchery Committee is currently evaluating the proposal to determine whether the extra production will affect HCP production. Ferguson asked how much extra production is being discussed, and Kirk Truscott said a half-million fish. Tom Kahler said the extra production will be reared in the large dirt ponds and the question is whether there is adequate incubation space. Ferguson asked about

funding, and Chad Jackson said this effort is being conducted under a contract between WDFW and Douglas PUD, which is passing through funds from the Washington legislature. Ferguson asked if there are any other logistical issues. Jackson said WDFW is currently navigating through various Endangered Species Act permits alongside several other hatcheries that are also planning extra production for orcas. Truscott noted that there are contingency plans in place in case permits get hung up, so these fish will go somewhere other than into the ground. Jackson said Douglas PUD's contingency plan is Banks Lake. Kahler also noted if other hatcheries are battling columnaris issues, there may be a need for extra fish from Wells Fish Hatchery.

- *Draft 2020 Rock Island and Rocky Reach M&E Implementation Plan (Rock Island/Rocky Reach):* Chelan PUD provided the draft 2020 Rock Island and Rocky Reach M&E Implementation Plan for review. The Rock Island and Rocky Reach HCP Hatchery Committees are currently reviewing the draft implementation plan and will discuss and vote on the plan during the HCP Hatchery Committees meeting on September 18, 2019.
- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on September 18, 2019.

III. Subyearling Studies

A. Brainstorming Session (All)

John Ferguson recalled the HCP Coordinating Committees convening a subyearling workshop in 2016, and then the subsequent Chelan PUD subyearling phase designation SOA, which is now about to expire, and the subyearling presentation provided by Dr. Rebecca Buchanan during the HCP Coordinating Committees meeting on July 23, 2019. Ferguson said based on Buchanan's presentation, in terms of survival models, project survival is still not separately estimable which is the same situation as 3 years ago. He said the question remains, where to go from here, and the HCP Coordinating Committees agreed further discussion was needed this month.

Ferguson said Keely Murdoch provided an email summarizing the Yakama Nation's (YN's) stance on subyearling studies, which was distributed to the HCP Coordinating Committees by Kristi Geris on August 12, 2019. Ferguson said the email is consistent with what Murdoch expressed verbally during the HCP Coordinating Committees meeting on July 23, 2019, i.e., the YN is interested in conducting at-dam passage survival studies similar to what the U.S. Army Corp of Engineers (USACE) has been doing. Ferguson noted, however, that at-dam passage survival studies are not stipulated in the HCPs as a means for achieving Phase III (Standard Achieved), and if this is a path the HCP Coordinating Committees choose to go down this will not be a simple discussion because it is a departure from the Passage Survival Plans in the HCPs. He said this may even require HCP Policy Committees input because at-dam passage survival studies are only an interim measure in the HCPs for getting out of

Phase II (Additional Tools), and the HCPs do not include the flexibility to study just for the sake of studying. He said the HCP Coordinating Committees would need to carefully consider this approach.

Jim Craig questioned whether studying survival at the dam is a significant enough departure from the HCPs to be in conflict with the HCPs. Lance Keller pointed out that achieving the 95% dam passage survival standard does not lead to a change in phase designation from Phase III (Additional Juvenile Studies) to Phase III (Standard Achieved). Keller said the HCPs are designed to carry out actions to define a phase designation on a project scale that is subsequently used to identify mitigation targets.

Kirk Truscott said currently under the HCPs, there is a negotiated level of mitigation for all Plan Species. He said the question is, is this enough mitigation for species for which survival has not been measured? He said if the PUDs conduct at-dam survival studies and the results are less than the negotiated value, does mitigation need to increase? He said conversely, if the results are better (higher survival), does this mean the negotiated mitigation is too much or does it not apply because this is only at-dam survival. He said, while everyone wants to know if Plan Species are being under-mitigated, this is not a two-way street. He said the risk is entirely on the PUD side and he is unsure whether this is fair. He said further, only fish of taggable size are being mitigated for, based on the studies, which is not the entire population.

Keller said after the last HCP Coordinating Committees meeting on July 23, 2019, he went back internally and discussed what has been learned about spring species, how this effects operational changes (especially at Rock Island Dam), and what is known about passage routes. He said, for example, what if Chelan PUD conducts an at-dam survival study and results are higher than 95% survival for 20% spring spill. He asked, does this mean Chelan PUD could conduct a spill reduction similar to the additional studies conducted in 2007 to reduce fish spill at Rock Island Dam from 20% to 10% for spring Plan Species after Phase III (Standards Achieved) was designated in 2006.

Truscott said he is interested in a tagging option to incorporate all fish lengths, but there are none. He said fish are marked with Bismarck brown dye at screw traps, but this would not remain visible for the duration needed for a survival study. He said it may work for an at-dam survival study or at least in proximity to a project. He said another sample location would also be needed, like a bypass. Tom Kahler said it would be difficult to recapture enough fish to have statistically significant results. Truscott suggested conducting a mass marking effort to boost sample size. He said, for example, marking 50,000 to 75,000 fish of all sizes at the confluence of the Okanogan River. He caveated that the current sampling scheme at the Rocky Reach Juvenile Fish Bypass is not sufficient to recover an adequate sample size; therefore, operational changes would be needed at the bypass. Keller agreed there would be logistical issues to recover the fish. Ferguson asked if there is an option for in-reservoir collection? Truscott said this would be nearly impossible. He said a fixed location would be needed to operate all day. Keller said even then, there would be detectability issues. He said at Rocky Reach Dam, Chelan PUD has staffed the bypass continuously for 40-some days, 24 hours per day, with samples conducted at the top of each hour. He said there needs to be high detection probability to calculate a survival estimate and he questioned whether a study design could reasonably handle that many fish. He said even with a PIT-tag study, there needs to be additional downstream handling sites to improve detection probability. He also noted that detection probability at the Rock Island Dam Juvenile Bypass System is low.

Truscott said there are obvious difficulties in attempting to conduct an at-dam or project-level, population-at-large, study, and he has no suggestions on how to arrive at something more tangible. Jim Craig said additionally, there are unknowns about life histories, such as fish residing versus moving slowly. Truscott said it might be useful to discuss what constitutes an active migrant and suggested considering migrating birds as a reference point. Kahler said, however, there is a difference between migrating birds and migrating fish. He explained that migrating birds move volitionally through an air mass, versus a fish not swimming will still be passively transported through their native water. He said fish do not have a choice to avoid migrating unless the fish actively resists it. He said Tiffan et al (2018)[1], also referenced in Douglas PUD's *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report*, distinguished what is an active versus passive migrant for the purposes of their study. Kahler said their method considers the ratio of the velocity of the fish relative to the velocity of the current. He said a fish moving slower than the current is considered a passive migrant versus a fish moving faster than the current is identified as an active migrant. He said perhaps the HCP Coordinating Committees can develop something similar to this.

Kahler said he does not recall whether Tiffan et al (2018)[1] mentioned water particle transport time nor is he certain this transit time is the same timing non-swimming creatures experience, but when Chief Joseph Dam increases discharge, it takes only a few hours for a wave of water to reach Wells Dam; however, the actual water-particle transit-time is calculated differently and is between 1 and 2 days. He said he is unsure how this is calculated but this water transit time is recognized by the Washington State Department of Ecology. Keller said according to the operators, water transit time from Rocky Reach Dam to Rock Island Dam is 45 minutes. Truscott said considering this timing yearlings would be passive. Kahler said in the Douglas PUD survival study, release times at Pateros were intended to match with release times in the Wells Dam tailrace, and those releases linked up pretty well. Keller said in the Chelan PUD survival study, the test and control groups were released 24 hours apart and travel time was species dependent. He said, for example, sockeye salmon migrated through the Rocky Reach Reservoir faster than yearling Chinook salmon or steelhead.

---

[1] Tiffan K. F., T. J. Kock, W. P. Connor, M. C. Richmond, and W. A. Perkins. 2018. Migratory behavior and physiological development as potential determinants of life history diversity in fall Chinook salmon in the Clearwater River. Transactions of the American Fisheries Society 147:400-413.

Truscott also noted that even though fish might be tailing (or moving tail-first), this does not necessarily mean the fish is not an active migrant.

Keller said additionally, the term "residualization" has been used a lot while discussing subyearling survival studies. He said this term is used a lot in the hatchery world to refer to a fish that chooses to not migrate and exhibits a life-history without an ocean component; however, when used in the context of natural-origin fish and survival studies it refers to a fish that will eventually out-migrate. Truscott agreed and added that, to residualize in the hatchery world refers to a reservoir-rearing life history. He said historically, there have been years with a fairly large amount of hatchery adult returns demonstrating this life history, but it has somewhat gone away over the past 6 to 8 years. Kahler agreed this life history has diminished.

Ferguson clarified that the term "active migrant" is not in the HCPs; rather, the HCPs only indicate "migrant." Truscott said active migrant is used in Douglas PUD's subyearling report and Keller said this term is also used in Buchanan's subyearling presentation. Chad Jackson said a survival study needs study fish that want to migrate. Kahler said for an acoustic tag study, according to Buchanan's subyearling presentation, any fish that does not migrate before the tag life expires is a residual fish.

Keller recalled in 2011, a similar situation of not being able to evaluate subyearlings, so Chelan PUD provided a presentation on what was known about subyearlings, including a review of metrics such as carrying capacity, productivity, and limiting factors. He said this provided confidence to the HCP Coordinating Committees that even though subyearling survival could not be studied, these data indicated the species was doing quite well. He suggested perhaps in lieu of a survival study, something similar can be done now, i.e., review these same metrics to determine if the species is in the same situation and doing okay. He recalled Tracy Hillman presented a productivity model for summer Chinook salmon in the Wenatchee and Methow river basins. He said ambient air temperature, relative snowpack, and pacific decadal oscillation were found to be the largest determining factors related to abundance. Truscott also recalled that the data indicated from an abundance and hatchery smolt-to-adult ratio standpoint, the population seemed to be on par or doing better than yearlings.

Truscott said he does not believe conducting an at-dam study will give the direction needed for a change in phase designation. Jackson agreed the technology is not quite there yet to conduct a project-level survival study, and he asked if more can be learned about the study species. He said maybe too much focus is on trying to fit a "square subyearling peg" into a "round (John) Skalski study" hole. Jackson recalled Murdoch mentioning otolith chemistry or perhaps other studies conducted on a good faith effort in order to get more information. Jackson suggested maybe convening a subgroup to brainstorm potential studies tailored just for subyearlings. He asked if hatchery surrogates could be used for a study. Ferguson said he would argue against a subgroup because each HCP Coordinating Committees representative needs to be a part of this discussion. Jackson agreed with this reasoning. Kahler said when developing a hatchery surrogate, the intent is to match the wild fish population; however, with subyearlings, it is unknown what time frame or location to match.

Truscott asked how did the USACE study immigration or survival studies on the Snake River with fall Chinook salmon? He recalled the studies were at-dam survival. Kahler said USACE acoustically tagged run-of-the-river fish collected at the projects. He said these fish were of sufficient size, at 95 millimeters tagging size, and only 1% of the fish captured were too small to tag. Truscott asked about fish size at Rocky Reach Dam, and Keller said there is definitely a fry component there (less than 40 millimeters). Keller said the average fish size changes on a daily basis. He said throughout a season, there is a first pulse of larger hatchery fish followed by an "unknown" component where the average fish length grows over time. Ferguson said Billy Connor (U.S. Fish and Wildlife Service) conducted a study on non-hatchery natural subyearling migrant reservoir-rearing life history, which was published in Transactions of the American Fisheries Society in 2005. Ferguson said NMFS also conducted early fish transportation studies which compared the study fish to in-river controls. Ferguson said the study fish faired really well because the fish were big, but the number of fish used in the study was small. He said these fish with a reservoir life history adapted to all environmental conditions. Kahler said Tiffan has also conducted a lot of work on this.

Truscott asked if there is any information the HCP Coordinating Committees have not yet reviewed toward another study design. He asked, what other studies can be conducted?

Keller recalled Chelan PUD's initial project survival study conducted on yearlings, which resulted in survival in the 80th percentile and subsequently remained in Phase I (Testing). He said Chelan PUD continued sockeye salmon studies under a Phase II (Additional Tools) designation and learned year-to-year how to boost survival. Truscott said eventually survival targets for these species were met for representative conditions. Keller agreed, but said there was a way to evaluate project survival for these species. He recalled that yearlings remained in Phase I (Testing) but studying sockeye salmon under Phase II (Additional Tools) showed that no spill and loading of the powerhouse improved survival. He said once it was determined improvements in sockeye salmon survival would also translate to and benefit yearling Chinook salmon, Chelan PUD reinitiated phase designation studies for yearling Chinook salmon under the new operations. He said for subyearlings, however, as Buchanan outlined, there is no way to define true survival.

Truscott asked if there is value in determining whether fish are really gone or just offshore somewhere in the reservoir? Kahler said Douglas PUD has observed subyearlings offshore in the Wells Reservoir. Keller said there is a lot of variability in the Rocky Reach Reservoir. He noted in 2011 and 2012, however, unknown subyearling components were detected at Rock Island Dam above the tagging size threshold but were gone about a week later. Kahler said historical fyke net data indicate those fish are migrating out of the reservoir through mid-August and peaking in early August, which is long after these fish can be captured by beach seine. Truscott suggested using a small purse seine, but then asked, what does this information do to improve our knowledge towards conducting a survival study? He said he is not certain this is what was intended by the phase designation "Additional Juvenile Studies." Ferguson said it seems "Additional Juvenile Studies" is generic language. Truscott said he does not want to keep postponing an actual study.

Keller said that although the current Chelan PUD subyearling SOA expires on September 29, 2019, Chelan PUD does not feel it is necessary to rush into another SOA. He said further, another SOA does not preclude continuing these discussions. He said Chelan PUD intends to revisit subyearling survival studies at least once per quarter, as an ongoing agenda item. Truscott said he would be supportive of renewing an SOA and understands the administrative reasoning for doing so.

Truscott asked if the PUDs would be interested in considering other studies of subyearlings, even if there is no clear link to informing a future survival study. He suggested, for example, studying what happens to these larger fish offshore in the reservoir in late-August and September. He added that learning something additional might end up helping design a future survival study. Jackson agreed and said building a knowledge base until technology becomes available might reveal another survival study design other than Skalski's design.

Ferguson said with true project survival off the table, the options seem to include behavioral studies, scale collection, otolith microchemistry, and acoustic tracking. He asked if there are other tools? Truscott said he is partial to active tag studies and monitoring scales from adults to obtain information on what is successful. He said he wants to know what these fish are doing in the reservoir. Ferguson noted the really good water quality in the reservoir. Kahler agreed and said the temperature are ideal for growth. He added that temperatures do not get too warm until late-August, which might be an impetus for fish to move out.

Ferguson asked about Dual-Frequency Identification Sonar (DIDSON) studies within the reservoir. He suggested establishing a sampling grid throughout the reservoir, similar to stock assessment surveys, to get at what is present and when. Kahler said this gets into the issue of how to distinguish targets. He said there are clouds of stickleback, chub, and peamouth, among other species. Keller agreed and said at the juvenile fish size it is difficult to distinguish species. Kahler said this is why Douglas PUD used fyke netting during the development and testing of the bypass system; it was needed to identify the species of fish observed in the hydroacoustic beams in the turbine and spillway intakes. He said until about mid-August, almost all objects identified as fish in the hydroacoustic sampling are salmonids, but in mid-August the young-of-year resident fish reach the same size as the salmonids. Keller said mobile surveys are also not as effective as a fully deployed array. He said

Chelan PUD conducts mobile surveys for white sturgeon and there are times when fish are present, but the gear cannot pick up a signal.

Truscott asked if the acoustic arrays deployed in the Wells and Rocky Reach reservoirs for white sturgeon are adequate for monitoring distribution of subyearlings? Keller said the white sturgeon arrays in the Rocky Reach Reservoir are setup to operate at a different frequency compared to a juvenile system. Kahler said the same is true for the Wells Reservoir, that the system would need to be rewired for juveniles. Keller said Chelan PUD would need to deploy entirely different equipment in the Rocky Reach Reservoir.

Truscott said it may turn out that behavioral data might contribute to a survival study, but he understands this may be a hard sell. Keller said, notably when a study moves from passive to active technology the base cost increases significantly. Ferguson asked about radio tags. Keller noted the external component (long antenna) and the need to install different detection equipment.

Keller said Chelan PUD appreciates the HCP Coordinating Committees thoughts and discussion on this topic. He said the Chelan PUD Natural Resources Department is tracking this closely and has full support of Chelan PUD General Manager, Steve Wright, who is very connected to the natural resources world.

Ferguson asked the HCP Coordinating Committees if there are questions for Buchanan and Skalski. No questions were expressed, and Kristi Geris notified Buchanan and Skalski that there were no further questions for them.

B. Questions and Answers with Drs. Rebecca Buchanan and John Skalski (All)

John Ferguson said the HCP Coordinating Committees had no further questions for Drs. Rebecca Buchanan and John Skalski.

Lance Keller said he will share today's discussions internally with Chelan PUD. Ferguson asked the Rock Island and Rocky Reach HCP Coordinating Committees representatives if everyone is ready to vote on a reboot of Chelan PUD's 3-year subyearling SOA during the next HCP Coordinating Committees meeting on September 24, 2019, and representatives present agreed on moving forward with a vote next month. Keller said the SOA will essentially be the same as the last SOA with a new date and quarterly check-ins on subyearlings.

Ferguson also suggested conducting additional research, for example, review of scale data. Keller said a review of scale data is already available. Tom Kahler agreed and said in 2016, Andrew Murdoch (WDFW) provided a stock assessment presentation, which looked at proportional contributions of the subyearling, reservoir-reared, and yearling life-history tactics, as evidenced in scales from natural-origin summer/fall Chinook salmon broodstock and carcasses. Keller read from the HCP Coordinating Committees June 22, 2016 meeting minutes, as follows:

> *He (Jeff Korth, WDFW retired) said despite these issues, subyearlings seem to have been able to adapt. He asked what happened in 2002, such that summer and fall Chinook salmon counts in the Mid-Columbia Basin have been on the rise. Kahler said it was harvest. He added that in 2002, there was a significant reduction in the Canadian harvest allocation. Truscott noted that the exploitation rate is still high.*

Keller said he will update Keely Murdoch on subyearling discussions to date, including Chelan PUD's plan to request approval of a renewed SOA during the HCP Coordinating Committees meeting on September 24, 2019, that maintains subyearling Chinook salmon in Phase III (Additional Juvenile Studies) for the Rock Island and Rocky Reach projects for up to 3 years. *(Note: Keller discussed this topic with Murdoch, as described in an email distributed to the HCP Coordinating Committees by Kristi Geris on September 3, 2019.)*

Keller said he will also distribute to the HCP Coordinating Committees a draft SOA, maintaining subyearling Chinook salmon in the Rock Island and Rocky Reach projects in Phase III (Additional Juvenile Studies) for up to 3 years, for vote during the HCP Coordinating Committees meeting on September 24, 2019. *(Note: Keller provided a draft SOA to Geris on September 19, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*

IV. Chelan PUD

A. Rocky Reach Dam Turbine Unit C1 and C3 Update (Lance Keller)

Lance Keller said Turbine Unit C1 continues to be plagued by delayed delivery of necessary components for repair from the vendors. He said currently, Rocky Reach Dam mechanics are waiting on the wicket gate servo control. He said repairs are still progressing in some areas but are delayed in others waiting on delivery of this key component. He said the return-to-service date has now slipped slightly to January 2020. He recalled the conflict in scheduling for the recommissioning of Turbine Units C9 and C1. He said crews have never conducted concurrent unit commissioning and do not plan to do so; therefore, Turbine Unit C1 must be operational no later than April 1, 2020. He said this return-to-service date also provides confidence for this unit to be online in time for the 2021 survival study.

Keller said Turbine Unit C3 is out-of-service today for a periodic evaluation of the new Chesterton seals. He said the last assessment occurred a few weeks ago and everything looked good. He said since the last assessment, crews have improved their ability to measure oil volumes when filling and draining the turbine hub. He said he will distribute results from the Rocky Reach Dam Turbine Unit

C3 Chesterton seal tests to the HCP Coordinating Committees once they become available. *(Note: Keller provided an update on the Chesterton seal tests to Kristi Geris on September 19, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*

B. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said Turbine Unit B4 has also suffered a delay in delivery of the hydraulic power unit, which controls the oil pressure inside the unit. He said work is continuing on the unit and there is no delay in the repair schedule as of yet. He said crews are currently working on the discharge liner, which in some areas is ground down to a depth of 3 inches and then filled and ground smooth. He said crews are refilling these areas and prepping the surface to prevent re-cavitation. He said crews are learning a lot and gaining knowledge towards repairing Turbine Unit B1 after Turbine Unit B4 is complete.

Kirk Truscott asked, with these maintenance issues ongoing at both Rock Island and Rocky Reach dams, is there going to be a modified maintenance schedule so there are not these prolonged amounts of time of limited maintenance? He asked, is the plan to operate until it breaks or conduct more frequent maintenance to avoid complete breakdowns? John Ferguson said it seems this question assumes these issues are all maintenance-related; however, some of these issues are aging-related. Keller said some of the current issues are due to deferring maintenance to accommodate other needed work, and he does not believe this is the fashion in which Chelan PUD prefers to operate. He said other current issues, such as the design flaws discovered in Rocky Reach Dam Turbine Units C8 to C11, were not maintenance related.

C. 2019 Rock Island and Rocky Reach Fish Spill Update (Lance Keller)

Lance Keller said at Rocky Reach Dam, summer fish spill started on June 2, 2019, and ended on August 12, 2019. Keller said on August 12, 2019, the Columbia River Data Access in Real Time database (DART) estimated that 99.24% of the subyearling Chinook salmon outmigration had passed Rocky Reach Dam. He said as a double-check, Chelan PUD took the cumulative count divided by the number of days remaining in August and compared smolts-per-day to the bypass counts. He said when summer spill was shutdown, bypass counts were averaging 29 to 30 smolts per day. He said counts over the past 5 days averaged 7 smolts per day.

Keller said at Rock Island Dam, summer fish spill started on June 2, 2019, and ended on August 19, 2019. He said the criteria to end summer spill at Rock Island Dam were met early on; however, results of the double-check were very close to the daily bypass counts. He said Chelan PUD chose to take a conservative approach and waited to end spill until daily index counts dropped to an average of 15 smolts per day. He said immediately after shutting down spill daily counts dropped into single digits. He said since spill shutdown, average daily counts have been 5 smolts per day. He said DART estimated that 99.47% of the subyearling Chinook salmon outmigration had passed Rock Island Dam on August 19, 2019.

Keller said next, Thad Mosey (Chelan PUD) will draft the 2019 Rock Island and Rocky Reach Fish Spill Report and will present the results to the HCP Coordinating Committees during the September 24 or October 22, 2019 meetings.

D. 2019/2020 Rocky Reach Dam Adult Fishway Maintenance (Lance Keller)

Lance Keller said typically, adult fishway maintenance at Rocky Reach Dam is completed during the months of January and February each year. He said this year, Rocky Reach Dam mechanics asked Chelan PUD to request approval for an earlier outage to complete necessary work. He said the initial ask was for the entire month of December 2019, but this has been negotiated down to 2 weeks, which has been requested and approved in the past. He said work driving this request includes the recommissioning of Turbine Units C1 and C9. He said the Turbine Unit C9 commissioning might happen as early as December 2019, which requires a full mechanical crew and will occur on the heels of the Turbine Unit C1 commissioning. He said the refurbished wicket gates for Turbine Unit C9 are coming from a vendor in Spokane, Washington, are being sent 3 to 4 at a time, but that 1 to 2 gates are being sent back each time because the gates are not meeting tolerances or have bearing issues.

Keller said concurrently, tied to public power benefits, there are plans to improve the fish viewing windows. Public Power Benefits look for ways to use surplus energy sales to enhance local experiences for rate payers, with previous examples being free parking passes for local parks and free electric vehicle charging stations. He said currently, the windows are 4 feet above the ground and the new windows will stretch nearly from the floor to the ceiling, allowing smaller children to get eye-to-eye with fish ascending the Rocky Reach Dam adult fish ladder. He said the plan is requires cutting into the fishway, removing the existing windows, and re-installing and pressure-testing the new windows. He said the contractor is planning to complete this construction from January 1 to February 29, 2020.

Keller said lastly, this leaves one crew to complete the preventative, routine checklist, while the other crews complete the other tasks. He said this is a lot of work for one crew, but the additional 2 weeks will provide breathing room to complete all these maintenance activities and meet the water-up date of March 1, 2020.

John Ferguson summarized that the request is for an outage from December 16, 2019 to February 29, 2020. Keller added that if the work is completed early, the system will be watered up early, as well. He also clarified that Chelan PUD is not requesting agreement right now unless Rocky Reach HCP Coordinating Committee representatives are comfortable with voting right now. He said, however, Rocky Reach Dam mechanics would like to know if a schedule change is needed, sooner than later.

Kirk Truscott said there are not a lot of anadromous fish moving through the ladders during this time of year. He said he is unsure about Pacific lamprey. Keller said he is unsure whether Pacific lamprey would use the ladders for overwintering or for migration, but if encountered in the ladders during the fish rescues that accompany the dewatering of an adult fishway, these fish would be translocated upstream.

Rocky Reach HCP Coordinating Committee representatives present agreed to Chelan PUD's request to begin the 2019/2020 ladder maintenance outage at Rocky Reach Dam 2.5 weeks earlier than usual to allow more time to complete required work, contingent on approval by the YN. Rather than beginning work during the first week in January (per usual), maintenance work will begin on December 16, 2019. Keller said he will explain to Keely Murdoch Chelan PUD's request, and request that Murdoch provide the YN's approval of the request to the Rocky Reach HCP Coordinating Committee via email. *(Note: Keller discussed this topic with Murdoch and the YN agreed to Chelan PUD's request, as described in an email distributed to the HCP Coordinating Committees by Kristi Geris on September 3, 2019.)*

V. Douglas PUD

A. Wells Dam Bypass Update (Tom Kahler)

Tom Kahler said bypass operations at Wells Dam ended at midnight on August 19, 2019, per the operating plan and as distributed to the HCP Coordinating Committees by Kristi Geris that same day.

VI. HCP Administration

A. HCP Policy Committees July 9, 2019 meeting minutes (John Ferguson)

John Ferguson said edits and comments on the draft minutes are still being addressed by HCP Policy Committees representatives. He said once all edits are received, the revised minutes for approval will be distributed for a vote via email. He said he has not heard further discussion on this topic within the HCP Tributary Committees. He said there is an action item to convene the HCP Policy Committees in-person on an annual basis after completion of the HCP annual reports to touch base on activities and discussions over the past year.

B. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on September 24, 2019, to be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington.

The October 22 and November 26, 2019 meetings will be held by conference call or in-person at the Grant PUD Wenatchee office in Wenatchee, Washington, as is yet to be determined.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: November 20, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the September 24, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD office in Wenatchee, Washington, on Tuesday, September 24, 2019, from 10:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Chelan PUD will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item I-C).
- Chelan PUD will review with U.S. Fish and Wildlife Service (USFWS) the Colville Confederated Tribes' (CCT's) revisions to the Statement of Agreement (SOA) titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years*, and will confirm with USFWS approval of the SOA with these revisions (Item III-A). *(Jim Craig provided USFWS approval of the CCT's edits and revised SOA via email on September 26, 2019.)*
- Anchor QEA, LLC, will add a subyearling Chinook salmon check-in agenda item for Chelan PUD on HCP Coordinating Committees meetings occurring in February, May, August, and November, to continue to evaluate or monitor study design, tag technology, and life history information on a quarterly basis to better understand future survival study feasibility by 2022, per the SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years* (Item III-A). *(Note: Kristi Geris added this reoccurring item to HCP Coordinating Committees meeting agendas beginning in February 2020.)*
- Douglas PUD will revise the *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019*, as discussed (Item IV-A). *(Note: Tom Kahler provided a revised draft document to Kristi Geris following the HCP Coordinating Committees meeting on September 24, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Wells HCP Coordinating Committee representatives will review the revised *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During*

April 2019 and will be prepared to discuss a path forward during the HCP Coordinating Committees meeting on October 22, 2019 (Item IV-A).

- Anchor QEA will coordinate with Denny Rohr (Priest Rapids Coordinating Committee [PRCC] Facilitator) and Grant PUD regarding rescheduling the HCP Coordinating Committees and PRCC's meetings in November and December 2019 to accommodate the holidays (Item V-C). *(Note: Anchor QEA and Rohr coordinated rescheduled dates, as discussed.)*
- The HCP Coordinating Committees meeting on October 22, 2019, will be held in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item V-C).

Decision Summary

- Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years*, as revised (Item III-A). *(Jim Craig provided USFWS approval of the revised SOA via email on September 26, 2019.)*

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- The *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019.
- The *Northern Pikeminnow Predator Control Program, Rocky Reach and Rock Island Hydroelectric Projects, Draft Summary Report, 2018* was distributed to the HCP Coordinating Committees by Kristi Geris on September 10, 2019, and is available for a 30-day review with edits and comments due to Lance Keller by October 10, 2019. Chelan PUD will request approval of this report during the HCP Coordinating Committees meeting on November 19, 2019.
- A *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019* was distributed to the HCP Coordinating Committees by Tom Kahler during the HCP Coordinating Committees meeting on September 24, 2019, and a revised draft document was distributed to the HCP Coordinating Committees by Kristi Geris following the HCP Coordinating Committees meeting on September 24, 2019 (Item IV-A).

Finalized Documents

- The final SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years* was distributed to the HCP Coordinating Committees by Kristi Geris on October 7, 2019 (Item III-A).
- The Final 2017 Douglas PUD Pikeminnow Removal Annual Report was distributed to the HCP Coordinating Committees by Kristi Geris on October 22, 2019, as approved by the Wells HCP Coordinating Committee after no disapprovals were received prior to the 60-day review deadline on March 28, 2019.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Tom Kahler added a 3-year performance review of the HCP Coordinating Committees Chair
- Lance Keller removed the *Rock Island and Rocky Reach 2019 Fish Spill Season Report*
- Ferguson added a Yakama Nation (YN) HCP Tributary Committees representation designation

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft August 27, 2019 meeting minutes. John Ferguson said in the first revised draft minutes (distributed to the HCP Coordinating Committees by Kristi Geris on September 17, 2019), under the Subyearlings Studies discussion, Chelan PUD and Douglas PUD provided text clarifying the discussion about phase designations and at-dam passage survival studies. Ferguson said the text clarified that at-dam studies do lead to a phase designation (Phase III [Additional Juvenile Studies] or Phase II [Additional Tools]); however, at-dam studies do not lead to designation of Phase III (Standard Achieved) and thus a calculation for mitigation (i.e., do not lead to a calculated survival component for No Net Impact). Tom Kahler further explained that Douglas PUD did use at-dam passage calculations to get to Phase III (Additional Juvenile Studies) for subyearling Chinook salmon; however, the Wells Project will remain in this phase until a project-level survival study can be conducted. Kahler said if the HCP Coordinating Committees want to make at-dam studies a basis for hatchery compensation, this is not currently stipulated in the HCPs and would be a major change to the HCPs.

Geris said a second revised draft minutes were distributed on September 19, 2019, which included Chelan PUD responses to three outstanding comments, which are tracked in redline strikeout. The HCP Coordinating Committees reviewed these additional edits. Geris said all other comments and revisions received from members of the Committees were incorporated into the revised minutes.

The HCP Coordinating Committees members present approved the August 27, 2019 meeting minutes, as revised. The YN abstained, because a YN representative was not present during the August 27, 2019 meeting.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on August 27, 2019, and follow-up discussions, were as follows. *(Note: Italicized text corresponds to agenda items from the meeting on August 27, 2019):*

- *Lance Keller will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item I-C).*
  This will be discussed during today's meeting and will also be carried forward.
- *Douglas PUD will review available passive integrated transponder (PIT)-tag detection data from April 9 to April 30, 2019, covering the span of Wells Dam bypass non-compliance events for Turbine Units 1 to 4 and Bypass Bays 2 and 4, to identify possible impacts to fish passage and survival through the Wells Project (Item I-C).*
  This will be discussed during today's meeting.
- *Kirk Truscott will submit CCT comments on the Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report to Tom Kahler (Item I-C).*
  Kahler said Truscott provided CCT comments on the draft report prior to the HCP Coordinating Committees meeting on September 24, 2019. Kahler said he will review and address these comments.
- *Lance Keller will update Keely Murdoch on subyearling discussions to date, including Chelan PUD's plan to request approval of a renewed SOA during the HCP Coordinating Committees meeting on September 24, 2019, that maintains subyearling Chinook salmon in Phase III (Additional Juvenile Studies) for the Rock Island and Rocky Reach projects for up to 3 years (Item III-B).*
  Keller discussed this topic with Murdoch, as described in an email distributed to the HCP Coordinating Committees by Kristi Geris on September 3, 2019.
- *Lance Keller will distribute to the HCP Coordinating Committees a draft SOA, maintaining subyearling Chinook salmon in the Rock Island and Rocky Reach projects in Phase III (Additional Juvenile Studies) for up to 3 years, for vote during the HCP Coordinating Committees meeting on September 24, 2019 (Item III-B).*
  Keller provided a draft SOA to Kristi Geris on September 19, 2019, which Geris distributed to the HCP Coordinating Committees that same day.
- *Lance Keller will distribute to the HCP Coordinating Committees results from the Rocky Reach Dam Turbine Unit C3 Chesterton seal tests once they become available (Item IV-A).*

Keller provided an update on the Chesterton seal tests to Kristi Geris on September 19, 2019, which Geris distributed to the HCP Coordinating Committees that same day. Keller said he will also discuss this during today's meeting.

- *Lance Keller will explain to Keely Murdoch Chelan PUD's request to begin the 2019/2020 annual ladder maintenance work period at Rocky Reach Dam on December 16, 2019, which is 2.5 weeks earlier than usual, to allow more time to complete required work, and request that Murdoch provide the YN's approval of the request to the Rocky Reach HCP Coordinating Committee via email (Item IV-D).*
  Keller discussed this topic with Murdoch and the YN agreed to Chelan PUD's request, as described in an email distributed to the HCP Coordinating Committees by Kristi Geris on September 3, 2019.

II. HCP Hatchery and Tributary Committees Update

A. HCP Hatchery and Tributary Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on September 12, 2019:

- *Cottonwood Flats Connection Project Presentation:* Chelan County Natural Resources Department and their consultant (Natural Systems Design) provided an update on the status of the Cottonwood Flats Connection project on the Entiat River. This was a follow-up visit based on feedback provided to the sponsor from the Rocky Reach HCP Tributary Committee during the HCP Tributary Committees meeting on August 8, 2019. The Rocky Reach HCP Tributary Committee had supported the 240-cubic feet per second (cfs) connection (i.e., the floodplain will be activated when flows in the Entiat River are at 240 cfs or greater) but did not support the perennial alcove or the construction of a channel throughout the floodplain. Rather, the Rocky Reach HCP Tributary Committee recommended the construction of a short pilot channel to allow the river the opportunity to carve out a channel or channels on the floodplain. The sponsor and their consultant evaluated the recommendation from the Rocky Reach HCP Tributary Committee and determined it will create ponding on the floodplain and noted the uncertainty of flow paths forming on the floodplain. Given this information, the Rocky Reach HCP Tributary Committee recommended knocking down high points on the floodplain to help with flow-path development. In summary, the Rocky Reach HCP Tributary Committee recommended construction of the pilot channel and knocking down high points downgradient from the pilot channel to help with flow-path development. No channels other than the pilot channel will be constructed on the floodplain. The sponsor, their consultant, and the landowner (Chelan-Douglas Land Trust) agreed with this approach.

- *Evaluation of the Chair:* The HCP Tributary Committees conducted an evaluation of the HCP Tributary Committees Chair (Tracy Hillman). HCP Tributary Committees members indicated they were pleased with the Chair's performance and requested that Douglas PUD and Chelan PUD retain Hillman's services for another 3-year term. Hillman agreed to serve as the Chair for the Wells, Rocky Reach, and Rock Island HCP Tributary Committees for another 3 years.
- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on October 10, 2019.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on September 18, 2019 (*note: joint HCP Hatchery Committees/PRCC Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Relative Reproductive Success Timeline (joint):* Washington Department of Fish and Wildlife (WDFW) provided the HCP Hatchery Committees with a revised memorandum clarifying the extension of the Wenatchee Spring Chinook Salmon Relative Reproductive Success Study. Importantly, the last year of sampling DNA from natural-origin Chinook salmon at Tumwater Dam will be 2023. The Rocky Reach and Rock Island HCP Hatchery Committees approved the memorandum.
- *Broodstock Collection Protocols (joint):* WDFW prepared a Broodstock Collection Protocols Development SOA. The SOA provides a timeline for developing the Broodstock Collection Protocols. The Wells, Rocky Reach, and Rock Island HCP Hatchery Committees approved the SOA. In addition, and consistent with the SOA, the HCP Hatchery Committees began the process of updating the Broodstock Collection Protocols. The HCP Hatchery Committees are currently identifying important issues to cover in the Broodstock Collection Protocols and identifying who will lead the writeup of certain sections of the protocols.
- *Update Genetics Section of the Hatchery Monitoring and Evaluation (M&E) Plan (joint):* The HCP Hatchery Committees reviewed edits made to the genetics section of the Hatchery M&E Plan. Revisions were made to the M&E Plan based on recommendations provided by the Genetics Monitoring Panel. HCP Hatchery Committees members continue to edit the genetics section of the report and will review additional revisions to the report during the HCP Hatchery Committees meeting on October 16, 2019.
- *Alternative Broodstock Composition and Mating Strategies (joint):* Douglas PUD provided a presentation that reviewed hatchery broodstock and mating practices for conservation programs. The intent is to collect broodstock and implement mating strategies within the hatcheries that minimize negative genetic effects. Here, the focus is on whether to include jacks in broodstock and mating strategies. Douglas PUD will provide a paper to the HCP Hatchery Committees describing the different strategies and their consequences. The HCP

Hatchery Committees will continue to evaluate broodstock collection and mating strategies for conservation programs.

- *National Marine Fisheries Service (NMFS) Consultation (joint):* NMFS has signed the steelhead and summer Chinook salmon permits. The permits are waiting to be signed by the permittees. John Ferguson asked about the duration of the permits and Tom Kahler replied, 10 years.
- *Expanded Wells Summer Chinook Production for the Southern Resident Killer Whale Population (Wells):* WDFW prepared a proposal that will allow extra production of subyearling summer Chinook salmon at Wells Fish Hatchery. The extra production is intended to benefit the Southern Resident Killer Whale population. Prior to the HCP Hatchery Committees meeting on September 18, 2019, the Wells HCP Hatchery Committee reviewed and approved the proposal allowing extra production of summer Chinook salmon at Wells Fish Hatchery. Ferguson asked what the next steps are in this process and if funding is already available. Chad Jackson said funding is available and contracting is in place. He said the several orca programs are currently working through permitting with NMFS and making sure these efforts are not impacting priority mitigation programs. He said at Wells Fish Hatchery, the eggs have not yet been collected.
- *2019 Egg Treatment Study (Wells):* Douglas PUD provided a study plan that will evaluate the effects of salt, hydrogen peroxide, and elemental copper in controlling saprolegnia infection of summer Chinook salmon eggs during incubation at Wells Fish Hatchery. The Wells HCP Hatchery Committee approved the pilot study, which will begin this fall 2019.
- *Draft 2020 Rock Island and Rocky Reach M&E Implementation Plan (Rock Island/Rocky Reach):* Chelan PUD provided the Rock Island and Rocky Reach HCP Hatchery Committees with the Draft 2020 Rock Island and Rocky Reach M&E Implementation Plan, which was approved by both committees.
- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on October 16, 2019, which is when Hillman said he expects the HCP Hatchery Committees Chair evaluation results will be discussed.

III. Chelan PUD

A. DECISION: Rock Island and Rocky Reach Subyearling Chinook Salmon SOA (Lance Keller)

Lance Keller said a draft SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years* was distributed to the HCP Coordinating Committees by Kristi Geris on September 19, 2019. Keller said the draft SOA is updated from the version approved in 2016, as discussed during the HCP Coordinating Committees meeting on August 27, 2019. He said this includes date changes, an addition to the Agreement Statement to review study designs on a quarterly basis, and updating text in the Background to make it current. He recalled reviewing study designs on a quarterly basis was discussed under the former SOA; however, now this language is actually included in the SOA.

Kirk Truscott suggested the following edits *(note: edits are shown in underlined and strikeout text)*:

Section	Proposed Text
Agreement Statement	The Rock Island and Rocky Reach HCP Coordinating Committees (CC) were presented data regarding the requirements of statistical survival models, tag technology, and life-history attributes for subyearling summer Chinook project survival studies in the Mid-Columbia, and agree that valid juvenile project survival measurements are not currently feasible.
Background	Current statistical survival models cannot calculate project survival as they are currently unable to address ~~active and non-active migrants~~ variable juvenile migration characteristics.
Background	These factors, in combination with ~~yet unknown proportions of migrant vs. non-migrant juvenile fish in~~ variable juvenile migration characteristics within the population remain impediments to project survival estimations for subyearling Chinook.

Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years*, as revised. John Ferguson said Jim Craig provided USFWS approval of the draft SOA via email on September 19, 2019. Keller said he will review Truscott's revisions to the SOA with Craig and will confirm USFWS still approves the SOA with these revisions. *(Craig provided USFWS approval of the CCT's edits and revised SOA via email on September 26, 2019.)*

Ferguson asked about timing for the quarterly updates and suggested starting in February 2020 since the HCP Coordinating Committees just discussed this topic in detail. Keller also suggested including the month of November as one of the quarterly updates because this is when U.S. Army Corps of Engineers holds their annual Anadromous Fish Evaluation Program, which often presents on the latest technology and studies. Ferguson said Anchor QEA will add a subyearling Chinook salmon check-in agenda item for Chelan PUD on HCP Coordinating Committees meetings occurring in February, May, August, and November, to continue to evaluate or monitor study design, tag technology, and life history information on a quarterly basis to better understand future survival study feasibility by 2022, per the SOA titled *Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years*. *(Note: Geris added this reoccurring item to HCP Coordinating Committees meeting agendas beginning in February 2020.)*

The final SOA was distributed to the HCP Coordinating Committees by Geris on October 7, 2019.

B. Rocky Reach Dam Turbine Unit C1 and C3 Update (Lance Keller)

Lance Keller said there are no new updates on Rocky Reach Dam Turbine Unit C1.

Keller said an update on the Rocky Reach Dam Turbine Unit C3 Chesterton seal tests was distributed to the HCP Coordinating Committees by Kristi Geris on September 19, 2019. Keller said Turbine Unit C3 was removed from service on August 26, 2019. He said the unit was dewatered to inspect the hub. He said two blade seals were found to have small oil leaks. He said upon draining the oil from the turbine hub, approximately 24 ounces of water was found. He said engineers indicated that these systems are designed to be able to function with a little water in the hub, and also noted that 24 ounces of water in the approximately 2,000 gallons of oil removed from the hub is a very small and acceptable amount of water to be found in the turbine hub. He recalled that crews also now have an improved ability to measure oil volumes when filling and draining the turbine hub, using what is called a "totalizer." He said another new set of trunnion seals, manufactured as a second option in the event that the initial set of Chesterton seals failed, were also installed in the two blades. He said these seals are similar to the Chesterton seals and are also equipped with an o-ring to wipe the seal surface. He said these additional seals were installed, mechanics conducted a pressure test, moved the blades back and forth, and no leakage was observed. He said crews returned Turbine Unit C3 to service on September 6, 2019, and periodic removal from service events are planned to conduct similar inspections.

John Ferguson asked if the successes in repairing Turbine Unit C3 will now be applied to the other units, or is Chelan PUD still researching other repair options? Keller said he is unsure of a definite plan. He said all of the engineering work on hydraulically locking the blades into place via a governor control is still on the shelf and he is unsure of that status. He said as of now, there has been good success with the two seal options, with the second design seemingly performing even better than the first.

C. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said there are no new updates on Rock Island Dam Turbine Unit B4. He said work on the draft tube continues to move forward and Chelan PUD is still struggling with the delivery of needed replacement parts to the site.

IV. Douglas PUD

A. Wells Dam Bypass Analysis of Probable Impacts of April 2019 Non-Compliance Events (Tom Kahler)

Tom Kahler distributed hard copies of a *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019* (Attachment B), which Kristi Geris distributed electronically to the HCP Coordinating Committees following their meeting on September 24, 2019.

Kahler noted that Appendix A (listed under Methods on page 1 of Attachment B) refers to the initial document provided to the HCP Coordinating Committees, which summarized Wells Dam bypass operations in April 2019 (titled, *Summary of Wells Dam Bypass Operations in April 2019*, distributed to the HCP Coordinating Committees by Geris on May 10, 2019).

Kahler said he developed a formula (Equation 1, Attachment B) to estimate the additional mortality that may have resulted from the Wells Dam bypass system not operating during a portion of April 2019. He said Equation 1 includes several parameters, which attempt to capture estimated passage timing for the different Plan Species spring emigrants, different non-compliance dates and times, and probable passage routes (Attachment B).

Kahler said Figures 1, 2, and 3 of Attachment B show coho salmon (Figure 1), steelhead (Figure 2), and yearling Chinook salmon (Figure 3) PIT-tag detections at the Rocky Reach Juvenile Fish Bypass System adjusted to represent Wells Dam passage dates based on estimated travel times (left y-axis). He said these figures also show the proportion of each day during which bypass operations were out of compliance (right y-axis and y_i in Equation 1). He said sockeye salmon and subyearling Chinook salmon passage dates at Wells Dam had no overlap with the bypass non-compliance dates. He noted for coho salmon, the earliest four migrants overlapped with dates when the bypass was out of compliance. He said because there are no time stamps for passage events at Wells Dam and these dates are back calculated based on travel time to Rocky Reach Dam, there is no way to confirm whether these fish passed Wells Dam during hours when the bypass was non-compliant. He said conservatively, the results assume these four fish passed during the hours when the bypass was not operating.

Kahler said fish are attracted to the face of Wells Dam by the discharge through turbine units since the bulk of the discharge through the dam is via operating turbines, and the idea of the bypass system is to have those fish that approach the dam pass via modified spillways located above turbine intakes. With 10 turbines at Wells Dam, Equation 1 assumes there is equal probability (0.1) a fish will encounter the dam at any one of these turbines. He said records are available showing which turbine units were operating during the non-compliance dates and times; however, parsing out passage routes and mortality rates gets complicated because we do not know what time a fish actually passed Wells Dam. To simplify the estimation of impacts, we assumed that a fish estimated to have passed Wells Dam on a date of non-compliant bypass operations could have passed at any time, and we multiplied the proportion of fish calculated to have passed on that date (x_i in Equation 1) by the proportion of that date during which bypass operations were non-compliant (y_i in Equation 1).

Kahler said the parameter $P(b_i)$ in Equation 1 represents the probability of a fish encountering the dam at a non-compliant bypass unit. He said, $P[t_i]$ in Equation 1 is the probability that the fish encountering the dam at a non-compliant bypass will pass via a turbine located below a bypass spillway. Andrew Gingerich added that a fish passing via a turbine route does not mean the fish dies. Kahler said this is correct; in fact, smolts survive turbine passage at high rates.

Kahler said Equation 1 sums all daily calculations of proportions of additional mortality for each date on which bypass operations were non-compliant to generate a total additional mortality as a proportion of detected emigrants (Estimated Additional Mortality, or *A* in Equation 1). Table 1 (Attachment B) shows those sums for each Plan Species. He said the Adjusted Survival Rate is the Estimated Additional Mortality subtracted from the measured survival value 0.9630. He said the Current Mitigation Rate is the rate established by the multi-year average of all of the survival studies for yearling spring migrants (or 7% for those Plan Species in Phase III [Additional Juvenile Studies]), and the Adjusted Mitigation Rate was calculated by adding the Estimated Additional Mortality to the Current Mitigation Rate. He said multiplying the Estimated Additional Mortality for each Plan Species by the total number of that species released or naturally produced above Wells Dam results in an estimate of the number of that species potentially affected by the non-compliant bypass operations (assuming that the distribution of emigration timing for the tagged fish used in the estimation represents the timing distribution for the run at-large). Gingerich noted a few errors in Table 1.

Keely Murdoch asked how the survival rate was calculated for estimating additional mortality resulting from increased turbine passage. Kahler said the baseline rate under normal bypass operations was determined via bypass studies that calculated an estimated weighted average bypass efficiency of 92% (or 0.92) for yearling spring migrants translating to a 0.08 probability of turbine passage. The estimate of additional mortality is calculated as the probability of turbine passage under non-compliant bypass operations minus the probability under normal bypass operations (0.08). That difference is multiplied by an average probability of turbine-passage mortality from studies at multiple projects, because we do not have a value specifically for Wells Dam. Murdoch asked if this calculation is based on immediate mortality or also includes latent mortality. Kahler said these data are based off of survival studies, which only consider immediate mortality within the study reaches.

Murdoch asked how these non-compliance dates compare to release dates for hatchery spring Chinook salmon (springers). She said in Figure 3, it is likely the increasing numbers represent hatchery springers and those passing earlier are wild-origin springers. She said she is interested in understanding how these non-compliance dates might have affected wild versus hatchery fish. Kahler said among the approximately 19,000 yearling Chinook salmon shown in Figure 3, he believes almost all fish were hatchery-origin; however, the migration timing of untagged fish is unknown.

Murdoch suggested acknowledging these estimates are for hatchery fish only and effects to wild fish cannot be assessed. *(Note: after the meeting Kahler provided a revised version of Attachment B that included estimated additional mortality [0.0016] for 71 wild spring Chinook salmon included within combined sample of yearling Chinook salmon.)*

Kirk Truscott said Equation 1 assumes equal probability for a fish to pass via any turbine, but he asked if Douglas PUD has data on what proportion of fish pass through different turbines based on fyke net data? Kahler said the fyke-netting effort did not sample every passage route at once as would have been necessary to determine horizontal distribution of fish passage. He said, however, if turbine discharge is what attracts fish to approach the dam at a particular location, and a turbine unit is not running, fish would be attracted to other passage options.

John Ferguson asked about next steps. Kahler asked whether the Wells HCP Coordinating Committee is satisfied with this approach or if there are other ideas to quantify Estimated Additional Mortality. Truscott said the CCT would like time to further review the document. Gingerich suggested adding language to the document to address Murdoch's comments about the scope being limited to PIT-tagged hatchery-origin fish. Chad Jackson also suggested correcting the errors in Table 1. Murdoch said it would also be helpful to parse out springers from summer Chinook salmon (summers) in Table 1. Gingerich said typically, yearling summers are released later. Murdoch agreed and said one could assume all late detections are summers. Kahler noted that summers have different travel times, which will affect the calculations. *(Note: During the meeting, Kahler provided Estimated Additional Mortality numbers parsed out for springers and summers [0.0019], springers only [0.0022], and summers only [0.00098]; however, he noted in a revised version of Attachment B that the estimated additional mortality for wild spring Chinook salmon [0.0016] was lower than the estimate for combined yearling Chinook salmon [0.0019].)*

Truscott noted in Figures 1, 2, and 3, no single day has more than 6% to 7% proportion of emigrants passing Wells Dam (left y-axis). He said with most hatchery releases occurring on or around April 15, these values seem low. He said he would expect a larger proportion on several of these days. Kahler said releases out of the Methow and Twisp rivers were late this year. Gingerich said historically during low-water years, releases out of the Twisp River were postponed in hopes of having more water and turbid conditions in the river when the fish are released to provide additional cover for out-migrating fish and reduce losses to predation. He said there was a drought in the Methow River this year and perhaps fish were held longer for this reason.

Kahler said Douglas PUD will revise the *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019*, as discussed. *(Note: Kahler provided a revised draft document to Geris following the HCP Coordinating Committees meeting on September 24, 2019, which Geris distributed to the HCP Coordinating Committees that same day.)*

Wells HCP Coordinating Committee representatives will review the revised *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019* and will be prepared to discuss a path forward during the HCP Coordinating Committees meeting on October 22, 2019.

V. HCP Administration

A. YN HCP Tributary Committees Representation Designation (John Ferguson)

John Ferguson said a YN HCP Tributary Committees Representation Designation letter was received on September 23, 2019 and was distributed to the HCP Coordinating Committees by Kristi Geris prior to the HCP Coordinating Committees meeting on September 24, 2019. Ferguson said the letter designates Brandon Rogers as the YN HCP Tributary Committees Representative (formerly Lee Carlson) and designates Hans Smith as the YN HCP Tributary Committees Alternate (formerly Rogers).

B. 3-Year Performance Review of the HCP Coordinating Committees Chair (Tom Kahler)

Tom Kahler recalled there is an HCP requirement to review the performance of each HCP Committee Chair every 3 years. Kahler said initially, the HCP Committees conducted this review in person; however, in all subsequent years they have been satisfied conducting this review via email. Kahler said a poll was distributed via email inquiring about the performance of both the Chair and Anchor QEA services as a whole. Kahler said HCP Coordinating Committees representatives provided positive feedback and agreed to retain John Ferguson and Anchor QEA for another 3 years.

C. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on October 22, 2019, to be held in person at the Grant PUD Wenatchee office in Wenatchee, Washington.

John Ferguson suggested starting discussions about possibly rescheduling the HCP Coordinating Committees meetings in November and December 2019 to accommodate the holidays. The HCP Coordinating Committees discussed moving the dates, including possible conflicts with the HCP Hatchery Committees meetings and coordinating with the PRCC meetings. The following changes were suggested:

Regular Date/Time	Proposed Date/Time
HCP Coordinating Committees meeting on November 26, 2019, 10:00 a.m. to 2:00 p.m.	HCP Coordinating Committees meeting on November 19, 2019, 9:00 a.m. to 12:00 p.m.
PRCC meeting on November 27, 2019	PRCC meeting on November 19, 2019, 1:00 p.m. to 5:00 p.m.
HCP Coordinating Committees meeting on December 24, 2019, 10:00 a.m. to 2:00 p.m.	HCP Coordinating Committees meeting on December 17, 2019, 9:00 a.m. to 12:00 p.m.
PRCC meeting on December 25, 2019	PRCC meeting on December 17, 2019, 1:00 p.m. to NLT 5:00 p.m.

Ferguson also noted that the HCP Coordinating Committees meetings in November and December 2019 may be convened via conference call or canceled pending agenda items (to be determined). Kristi Geris said Anchor QEA will coordinate with Denny Rohr and Grant PUD regarding rescheduling the HCP Coordinating Committees and PRCC's meetings in November and December 2019 to accommodate the holidays. *(Note: Geris contacted Rohr and based on discussions with the PRCC, the HCP Coordinating Committees meeting on November 19, 2019, was changed to 1:00 p.m. to 5:00 p.m. to be held at the Wanapum Dam Hydro Office Building, and the HCP Coordinating Committees meeting on December 17, 2019, remained from 9:00 a.m. to 12:00 p.m. to be held at the Grant PUD Wenatchee office.)*

Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019

September 24, 2019

Background

From the Wells Project survival studies conducted to date, the four-year mean mortality rate through the Wells Project is 0.037, or 3.7 percent for "yearling spring migrants" (yearling Chinook, yearling coho, and steelhead smolts). This low rate of mortality is achieved because most emigrants pass Wells Dam via the bypass system, and bypass passage survival is effectively 100 percent. As the culmination of multiple years of bypass development and testing, Skalski et al. (1996) estimated the weighted mean bypass efficiency for emigrating steelhead smolts and yearling Chinook at 0.92, or 92 percent. In other words, 92 percent of steelhead smolts and yearling Chinook pass through Wells dam via the bypass, rather than the turbines.

Deviation from normal bypass operations that results in the operation of turbines without the normal operation of adjacent bypass facilities could increase the rate of turbine passage for those fish encountering the dam at the location of the affected bypass facilities. Such an increase in turbine passage could increase the mortality rate of fish passing during periods of non-compliant bypass operations.

Methods

During April of 2019, a series of events over several days resulted in multiple hours of bypass operations that deviated from normal bypass operations at Wells Dam (detailed in Appendix A). To estimate the additional mortality that may have resulted from the non-compliant operations for each plan species during April, 2019, we developed the following formula (Equation 1):

$$A = \sum_{i=1}^{n}(((x_i y_i \cdot P(b_i) \cdot P(t_i)) - (x_i y_i \cdot P(b_i) \cdot 0.08)) \cdot 0.1) \qquad \text{Equation 1}$$

Where:

A = Additional mortality (as a proportion of detected emigrants for each Plan Species) due to bypass non-compliance.

x_i = The number of detections on date *i*, divided by the total number of detections on all dates.

y_i = The proportion of date *i* affected by non-compliant bypass operations (number of non-compliant hours divided by 24 hours).

$P(b_i)$ = The probability of encountering the dam at an affected bypass on date *i*, which is a function of fish distribution across the project, turbine operation, and bypass-gate opening and barrier presence and configuration.

$P(ti)$ = The probability of turbine passage at an affected bypass on date *i*, which also is a function of turbine operation and bypass-gate opening and barrier presence and configuration.

0.08 = A constant; the weighted mean value of the probability of turbine passage for "yearling Chinook and steelhead" during normal bypass operations (i.e., 1 - bypass efficiency [0.92] = 0.08), as established during bypass testing (from Skalski et al. 1996).

0.1 = A constant; a reasonable value for the mortality rate experienced during passage of juvenile salmonids through Kaplan turbines such as those installed at the Wells Project, which typically ranges from 0.05 to 0.15 (from multiple studies at multiple projects).

Equation 1 calculates a total sum of the estimated additional mortality proportions resulting from the increased turbine passage that occurred on each date that bypass operations did not comply with the *2019 Bypass Operating Plan*, approved by the Wells HCP Coordinating Committee. The resultant sum is the proportion of additional mortality (beyond that under normal operations) of the total number of emigrating fish detected at the Rocky Reach Juvenile Bypass PIT-tag detection system (PTAGIS Site Code RRJ) for the 2019 juvenile emigration, calculated individually for each of the following Plan Species: yearling Chinook, subyearling Chinook, steelhead, coho, and sockeye.

We established Wells Dam passage dates by subtracting a Wells Dam-to-RRJ travel time from RRJ detection-event dates. We queried PTAGIS for juveniles detected at RRJ and also detected at WEJ (PTAGIS Site Code for the Wells Bypass Juvenile Sampling Array). Too few fish were detected at both facilities in 2019 to allow for a calculation of 2019 WEJ-RRJ travel time for each category of emigrants. Therefore, we used the combined data from all dual-detection events from 2016-2019 to generate WEJ-RRJ travel times. For Chinook and steelhead, data distributions had single modes but were right skewed, rendering the arithmetic mean a poor measure of central tendency for both. However, in both cases, the medians closely approximated the modes and harmonic means. Therefore, we used the median travel times for both steelhead smolts (2 days) and yearling Chinook (3 days), to back-calculate Wells passage dates. For coho smolts, the travel-time distribution was multimodal, and sample size was small; but, the median equaled the mean (5 days). Without enough PIT-tag-detection data with which to calculate WEJ-RRJ travel times for sockeye smolts, we used the mean travel time from the Wells tailrace to Rocky Reach Dam (1 day) generated by Chelan PUD from three years of survival studies (2007-2009) for the Rocky Reach project.

Because we estimated the passage date at Wells Dam, we could not match up actual passage times with the hours of non-compliant bypass operations on any given date. Thus, we could only assume the overlap of fish passage and non-compliant operation when a fish was estimated to pass on a given date, and this likely overestimated actual exposure to non-compliant bypass conditions since non-compliant operations never lasted all day (range: 1 to 18 hours).

We matched up the Wells passage-date distributions with the dates of non-compliant bypass operations, and found that all sockeye smolts and subyearling Chinook passed Wells Dam after those dates. For yearling Chinook, steelhead, and coho smolts, we applied Equation 1 for those dates on which passage events coincided with non-compliant bypass operations to generate the joint probability of additional mortality. Assuming that the distributions of passage events at Wells Dam, estimated from PIT-tag detections at RRJ, represents the runs at-large for yearling Chinook and coho, and steelhead smolts, we applied our estimates of additional mortality to the runs at-large for those Plan Species.

Results and Discussion

For coho yearlings, only 4 of 4,102 detected emigrants passed Wells on days when bypass operations were not compliant (Figure 1). In contrast, 11.9 percent of 15,861 steelhead smolts and 14.5 percent of 19,861 Chinook yearlings passed during non-compliant bypass operations (Figures 2 and 3, respectively). Despite that level of overlap, since the probability of increased turbine passage at the affected bypass bay(s) is the joint probability of multiple events, as expressed in Equation 1, the estimated additional mortality resulting from increased turbine passage is low. For each Plan Species, Table 1 lists the estimates of the proportional increased mortality and the resultant project survival from subtracting that increased mortality from the four-year project survival estimate from previous survival studies.

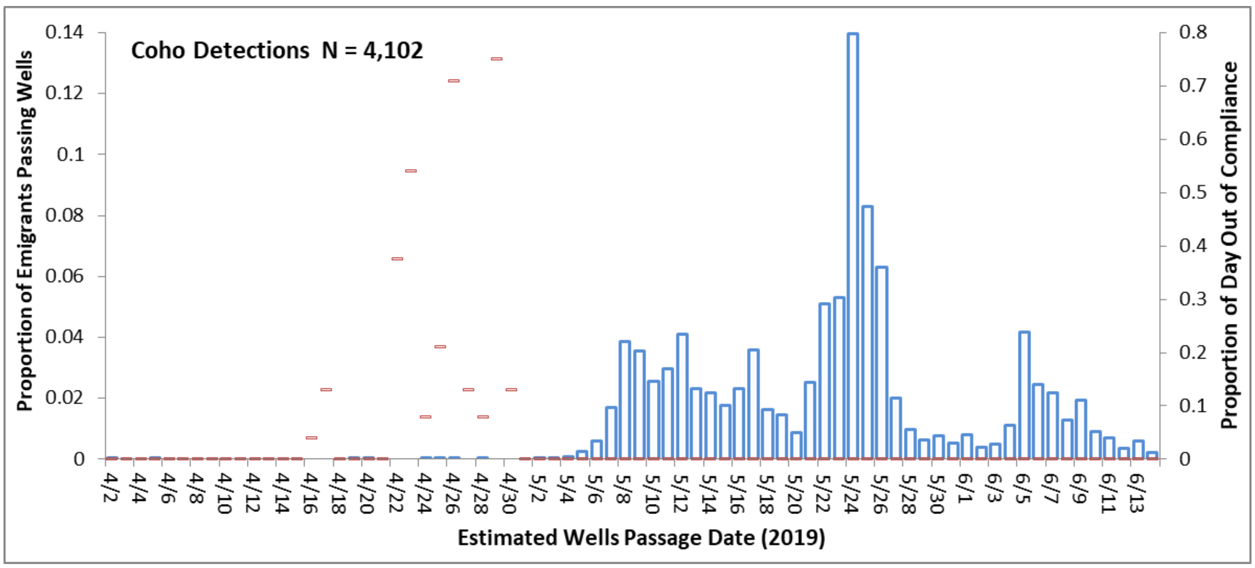

Figure 1. Yearling coho passage distribution at Wells Dam by date (left y-axis) as estimated by detection of PIT-tagged coho at RRJ. The proportion of coho emigrants on a given date (x_i in Equation 1) is represented by blue bars. The proportion of each day (right y-axis) during which bypass operations were out of compliance (y_i in Equation 1) is represented by red rectangles.

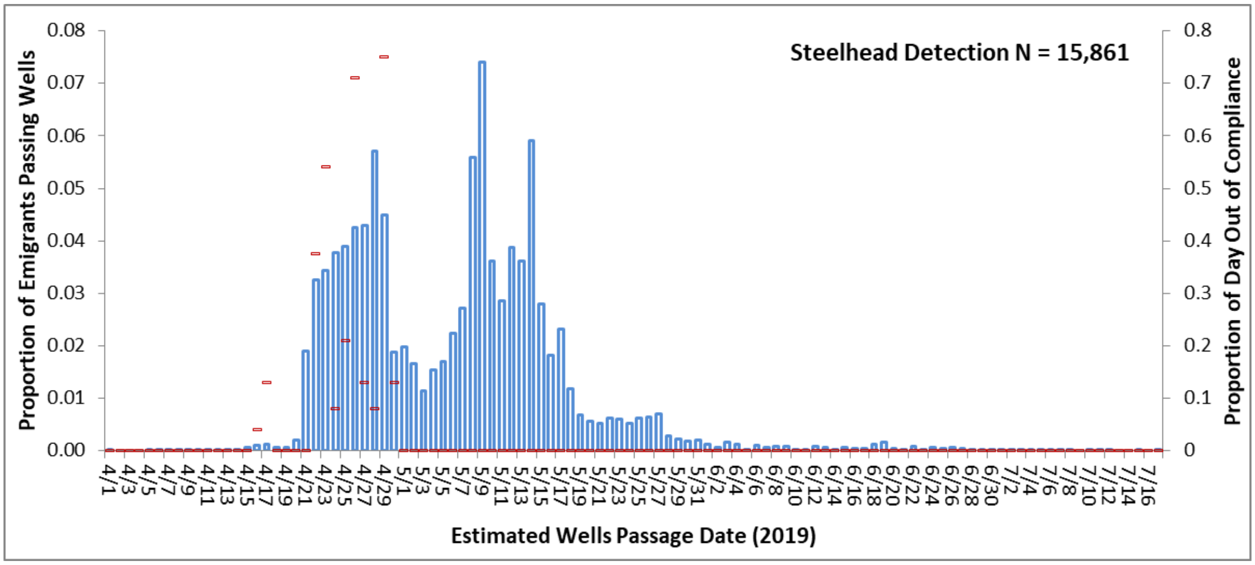

Figure 2. Steelhead smolt passage distribution at Wells Dam by date (left y-axis) as estimated by detection of PIT-tagged steelhead smolts at RRJ. The proportion of steelhead emigrants on a given date (x_i in Equation 1) is represented by blue bars. The proportion of each day (right y-axis) during which bypass operations were out of compliance (y_i in Equation 1) is represented by red rectangles.

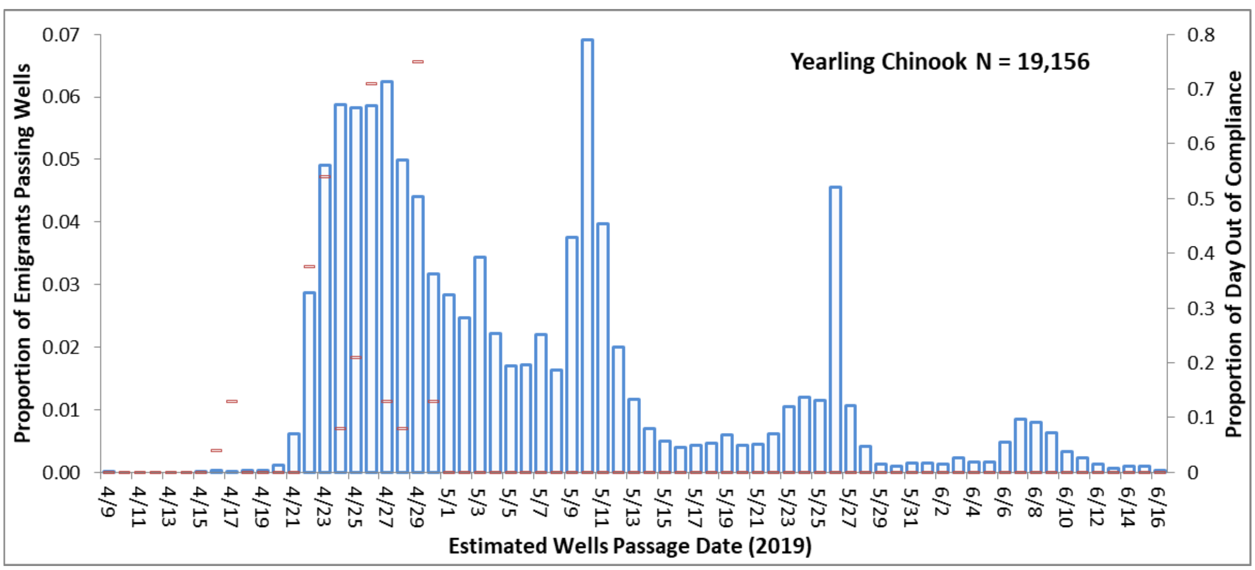

Figure 3. Yearling Chinook passage distribution at Wells Dam by date (left y-axis) as estimated by detection of PIT-tagged Chinook emigrants at RRJ. The proportion of Chinook emigrants on a given date (x_i in Equation 1) is represented by blue bars. The proportion of each day (right y-axis) during which bypass operations were out of compliance (y_i in Equation 1) is represented by red rectangles.

Table 1. "Estimated Additional Mortality" for each HCP Plan Species resulting from non-compliant bypass operations at the Wells Project during April 2019, as estimated by Equation 1. "Adjusted Survival Rate" is the Estimated Additional Mortality subtracted from the four-year-average survival value, 0.9630, for yearling spring migrants. "Current Mitigation Rate" is the hatchery production rate established for each Plan Species according to the current phase designations. "Adjusted Mitigation Rate" is the mitigation rate that would be necessary to compensate for the Estimated Additional Mortality, calculated by adding the latter to the Current mitigation rate.

Plan Species	Estimated Additional Mortality	Adjusted Survival Rate	Current Mitigation Rate	Adjusted Mitigation Rate
Sockeye	0	NA	7%	NA
Subyearling Chinook	0	NA	7%	NA
Coho	0.000003	0.962997	3.7%	3.70003%
Steelhead	0.0003	0.9627	3.7%	3.703%
Yearling Chinook	0.0019	0.9611	3.7%	3.719%

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees Date: December 17, 2019

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the November 19, 2019 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Wanapum Dam Hydro Office Building in Grant County, Washington, on Tuesday, November 19, 2019, from 1:00 p.m. to 4:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Chelan PUD will continue providing Rocky Reach Dam and Rock Island Dam turbine unit maintenance updates as information becomes available (Item I-C). *(Note: these agenda items will be reoccurring until repairs are complete.)*
- Chelan PUD will determine the reason behind omitting data from 1979 to 1982 from the original Grand Coulee flow duration curves dataset (1929 to 1978 and 1983 to 2001; Item III-A).
- Anchor QEA, LLC, will contact Chad Jackson regarding Washington Department of Fish and Wildlife (WDFW) approval of the *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019*, as revised (Item V-B). *(Note: Kristi Geris emailed Jackson on November 20, 2019, with this request and Jackson provided WDFW approval of the document via email on November 22, 2019.)*
- The HCP Coordinating Committees meeting on December 17, 2019, will be held at 9:00 a.m. (instead of 10:00 a.m.), in-person at the Grant PUD Wenatchee office in Wenatchee, Washington (Item VI-B).

Decision Summary

- Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the *Northern Pikeminnow Predator Control Program, Rocky Reach and Rock Island Hydroelectric Projects, Draft Summary Report, 2018* (Item IV-A). *(Note: Chad Jackson provided WDFW approval of the draft report via email on November 12, 2019.)*
- Wells HCP Coordinating Committee representatives present approved the *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019*, as revised (Item V-B). *(Note: Chad Jackson provided WDFW approval of the document via email on November 22, 2019.)*

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- The *Wells Project Subyearling Chinook Life-History Study 2011-2013 Draft Final Report* was distributed to the HCP Coordinating Committees by Kristi Geris on May 24, 2019.
- The *Chelan PUD Rocky Reach and Rock Island HCPs Draft 2019 Fish Spill Report* was distributed to the HCP Coordinating Committees by Kristi Geris on November 19, 2019. Chelan PUD will request approval of the report during the HCP Coordinating Committees meeting on December 17, 2019 (Item IV-B).
- The Passage-Dates Analysis portion of the 2019 Wells Dam Post-Season Bypass Report was distributed to the HCP Coordinating Committees by Kristi Geris on November 19, 2019, and the 2019 Wells Dam Post-Season Bypass Report was distributed on December 5, 2019. Douglas PUD will request approval of the 2019 Wells Dam Post-Season Bypass Report and Passage-Dates Analysis during the HCP Coordinating Committees meeting on December 17, 2019 (Item V-A).
- The draft Statement of Agreement (SOA), *Regarding the Updated Flow-Duration Curves for the Wells Hydroelectric Project For Establishing Representative Environmental Conditions*, was distributed to the HCP Coordinating Committees by Kristi Geris on December 5, 2019. Douglas PUD will request approval of the draft SOA during the HCP Coordinating Committees meeting on December 17, 2019 (Item III-A).
- The draft SOAs, *Updated Flow Duration Curves for the Rock Island Project for Establishing Representative Flow Conditions* and *Updated Flow Duration Curves for the Rocky Reach Project for Establishing Representative Flow Conditions*, were distributed to the HCP Coordinating Committees by Kristi Geris on December 6, 2019. Chelan PUD will request approval of the draft SOAs during the HCP Coordinating Committees meeting on December 17, 2019 (Item III-A).

Finalized Documents

- The final *Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019* was distributed to the HCP Coordinating Committees by Kristi Geris on November 22, 2019 (Item IV-B).

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. No additions or changes were requested.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft September 24, 2019 meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. HCP Coordinating Committees members present approved the September 24, 2019 meeting minutes, as revised. The U.S. Fish and Wildlife Service (USFWS) abstained, because a USFWS representative was not present during the September 24, 2019 meeting. *(Chad Jackson provided WDFW approval of the revised minutes via email on November 12, 2019.)*

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on September 24, 2019, and follow-up discussions, were as follows. *(Note: Italicized text corresponds to agenda items from the meeting on September 24, 2019):*

- *Chelan PUD will provide updates about the repair of Rocky Reach Dam Turbine Unit C1 and Turbine Unit C3 to the HCP Coordinating Committees as soon as additional information becomes available (Item I-C).*
  This action item will be discussed during today's meeting and will also be carried forward.
- *Chelan PUD will review with USFWS the Colville Confederated Tribes' (CCT's) revisions to the SOA titled Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years and will confirm with USFWS approval of the SOA with these revisions (Item III-A).*
  Jim Craig provided USFWS approval of the CCT's edits and revised SOA via email on September 26, 2019.
- *Anchor QEA, LLC, will add a subyearling Chinook salmon check-in agenda item for Chelan PUD on HCP Coordinating Committees meetings occurring in February, May, August, and November, to continue to evaluate or monitor study design, tag technology, and life history information on a quarterly basis to better understand future survival study feasibility by 2022, per the SOA titled Maintain Rock Island and Rocky Reach Subyearling Chinook in Phase III (Additional Juvenile Studies) for up to Three Years (Item III-A).*
  Kristi Geris added this reoccurring item to HCP Coordinating Committees meeting agendas beginning in February 2020.

- *Douglas PUD will revise the Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019, as discussed (Item IV-A).*
  Tom Kahler provided a revised draft document to Kristi Geris following the HCP Coordinating Committees meeting on September 24, 2019, which Geris distributed to the HCP Coordinating Committees that same day.
- *Wells HCP Coordinating Committee representatives will review the revised Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019 and will be prepared to discuss a path forward during the HCP Coordinating Committees meeting on October 22, 2019 (Item IV-A).*
  This will be discussed during today's meeting.
- Anchor QEA will coordinate with Denny Rohr (Priest Rapids Coordinating Committee [PRCC] Facilitator) and Grant PUD regarding rescheduling the HCP Coordinating Committees and PRCC's meetings in November and December 2019 to accommodate the holidays (Item V-C).
  Anchor QEA and Rohr coordinated rescheduled dates, as discussed.

II. HCP Hatchery and Tributary Committees Update

A. HCP Hatchery and Tributary Committees Update (John Ferguson)

John Ferguson updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on October 16, 2019 (*note: joint HCP Hatchery Committees/PRCC Hatchery Subcommittee items are noted by "joint," Wells HCP Hatchery Committee items are noted by "Wells," and Rock Island and Rocky Reach HCP Hatchery Committees items are noted by "Rock Island/Rocky Reach"*):

- *Update Genetics Section of the Hatchery Monitoring and Evaluation (M&E) Plan (joint):* The HCP Hatchery Committees reviewed and approved edits made to the genetics section of the Hatchery M&E Plan. Revisions were made to the M&E Plan based on recommendations provided by the Genetics Monitoring Panel. The HCP Hatchery Committees also discussed the spatial scale at which carcass data should be evaluated and concluded analyses will vary depending on the stock and species. At a minimum, all stocks will be evaluated at the historic reach scale. Analyses will determine and justify other scales of inference for each stock.
- *Improvement Feasibility at Eastbank Fish Hatchery for Wenatchee Summer Chinook Salmon SOA (joint):* Chelan PUD reported the ability to meet Wenatchee River Total Maximum Daily Load (TMDL) requirements for phosphorous discharged from hatchery production at the Dryden Acclimation Pond adjacent to the Wenatchee River. These requirements can be met

without implementing the 2016 SOA.[1] Therefore, the SOA is no longer needed to meet TMDL requirements at the Dryden Acclimation Pond.

- *Establishing Ranges Around Broodstock Collection Targets (joint):* Douglas PUD provided a presentation on *Managing Risk and Expectations in Broodstock Collection*. Douglas PUD described a modeling approach for determining the number of broodstock adults that would be required to meet juvenile production targets. The next step is to compare modeling results with the current method used to estimate broodstock collection targets.
- *Surplus Juvenile Spring Chinook Salmon Production (joint):* Douglas PUD indicated there are about 8,000 extra spring Chinook salmon eyed eggs at the Methow Fish Hatchery. Because the fecundity of 2019 broodstock was higher than expected, there are extra eyed eggs on station. The eyed eggs are from hatchery-origin eggs crossed with wild males. Members will see if the extra eyed eggs can be transferred to the Winthrop National Fish Hatchery or to the Chief Joseph Fish Hatchery.
- *Broodstock Collection Protocols (joint):* The HCP Hatchery Committees are in the process of updating the broodstock collection protocols. The HCP Hatchery Committees identified important issues to cover in the broodstock collection protocols and identified who will lead the writeup of certain sections of the protocols. Draft writeups are due to the HCP Hatchery Committees by the December meeting.
- *National Marine Fisheries Service (NMFS) Consultation (joint):* NMFS has signed the Steelhead and Summer Chinook Salmon permits. The permits are waiting to be signed by the permittees.
- *Next Meeting*: The next meeting of the HCP Hatchery Committees will be on November 20, 2019.

Ferguson updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on November 14, 2019:

- *Sugar Levee Ground Water Evaluation Project:* Methow Salmon Recovery Foundation is the sponsor of this project and the purpose is to evaluate groundwater levels and flow paths within the floodplain disconnected by the Sugar Levee along the Methow River between river miles 41 and 44. Results from this work will inform opportunities to reconnect the floodplain and relic side channels affected by levee development. The total cost of the project was $5,404. The sponsor requested $2,940 from HCP Plan Species Account Funds. The Wells HCP Tributary Committee elected to contribute $2,940 to the project.

[1] Rock Island and Rocky Reach HCP SOA titled, *Improvement Feasibility at Eastbank Hatchery for Wenatchee Summer Chinook*, approved by the Rock Island and Rocky Reach HCP Hatchery Committees on February 17, 2016, and distributed on February 18, 2016.

- *Cottonwood Flats Project:* The HCP Tributary Committees received an update from the project sponsor (Chelan County Natural Resources Department) on the Cottonwood Flats Project. Previously, the HCP Tributary Committees recommended that the sponsor use a "Light Touch" approach to reconnect the floodplain with the Entiat River. The sponsor indicated a preference to move forward with the original design (or a slightly modified design) to more easily justify or guarantee certain outcomes if the original design is implemented (the original plan was to construct a side channel though the floodplain; the Light Touch approach is to construct a short pilot channel and let high flows develop flow paths through the floodplain). The sponsor believes the Light Touch approach carries less certainty of success and limits the ability to guarantee certain outcomes. It also represents a significant departure from what the Salmon Recovery Funding Board (SRFB) originally approved. The HCP Tributary Committees appreciated the sponsor's position and concerns; however, the HCP Tributary Committees believe Cottonwood Flats represents a rare and unique opportunity to test the Light Touch approach. The HCP Tributary Committees therefore recommended that the sponsor consider working through the amendment process with the SRFB. The HCP Tributary Committees believe the SRFB will find favor with a less expensive project that still allows floodplain reconnection at certain flows. Cottonwood Flats provides an excellent opportunity to evaluate reconnecting a large floodplain using a Light Touch approach.
- *Next Meeting*: The next meeting of the HCP Tributary Committees will be on December 12, 2019.

III. Chelan PUD and Douglas PUD

A. Updated Flow Duration Curves (Lance Keller and Tom Kahler)

John Ferguson said flow duration curves are included in all three HCPs. He said the Rock Island and Rocky Reach HCPs stipulate updating the curves every 10 years, which Chelan PUD started doing in 2013 but then the Wanapum Dam incident occurred postponing the final updated curves. He said the Wells HCP only stipulates periodic review of the curves. He said Chelan PUD and Douglas PUD have been coordinating on this and Chelan PUD will present findings and proposals. He said the goal today is to have a good discussion. He said Chelan PUD and Douglas PUD will bring Chad Jackson up to speed after the meeting and hopefully the HCP Coordinating Committees will be ready to approve updated flow duration curves during the HCP Coordinating Committees meeting on December 17, 2019. Ferguson said this will capture the new curves in the 2019 administrative record and annual reports ahead of the next survival verification study in 2020.

Lance Keller said the Rock Island and Rocky Reach HCPs stipulate starting to update the original flow duration curves in 2013, which Chelan PUD did before the Wanapum Dam fracture. He said these curves are only really applicable while conducting project survival studies and the Wells and Rock Island projects completed and achieved survival study standards in 2010 and the Rocky Reach

Project did the same in 2011; therefore, updating these curves was postponed but with no negative impacts to the projects.

Keller said a presentation titled, *Wells, Rocky Reach, and Rock Island HCPs Update Representative Survival Study Flows* (Attachment B) was distributed to the HCP Coordinating Committees by Kristi Geris prior to the HCP Coordinating Committees meeting on November 19, 2019. Keller said he will first review the history of the flow duration curves and what the curves are utilized for. He said he will then address the questions asked of Chelan PUD by the HCP Coordinating Committees in 2013. He said lastly, he will present the proposals he and Tom Kahler have developed on how to best approach updating these curves for each HCP during the current review.

Slide 2 of Attachment B

Keller presented and read a quote directly from page 10 of the Rock Island HCP. He said this is the basis of the design and intent of the flow duration curves.

Slide 3 of Attachment B

Keller said the flow duration curves outline the bounds of a valid flow (from the 10th percentile mean flow to the 90th percentile mean flow) during the time frame in which a survival study is conducted (spring or summer). He said the original curves were constructed based on out-flows from Grand Coulee Dam. He said these same curves were applied to the Wells, Rocky Reach, and Rock Island projects. He said the spring study period extends from April 16 to May 31 and the summer study period from July 1 to August 15. He said in 2013, the intent was to integrate the last 10 years of flow data into the existing flow duration curves dataset, rank the flows, and develop new updated curves.

Kirk Truscott asked if bullets 1 and 2 are exact language from the HCPs. Keller said this might not be the exact language, but this is how the curves are constructed.

Slide 4 of Attachment B

Keller said the original dataset includes 69 years of flow data. He said flows are ranked starting from highest to lowest, percentiles are calculated, and lines are drawn at the 10th and 90th percentiles. He said these are the bounds for a valid survival verification study based on river flow for all HCPs during for spring timeframe. He said the 1929 to 1978 dataset is HYDSIM modeled flow data and the 1983 to 2001 dataset is based on observed flow data.

Ferguson asked why the gap in datasets (1979 to 1982), and Keller said he believes these years were omitted because river flow was abnormally high, but he is unsure. Keller said he knows the years were omitted on purpose for a reason and he will find out why.

Keely Murdoch said she understands Grand Coulee Dam is key in controlling flow in the Columbia River, but she asked if it is possible that enough water comes out of the Wenatchee, Entiat, and Methow rivers such that river flow is above the 90th percentile in the Rock Island Project but this is not the case in the Wells Project? Keller said as currently written, even though these survival studies are carried out at the local project level, Chelan PUD and Douglas PUD still use flow data from Grand Coulee Dam. He said to Murdoch's point, he and Kahler developed a slide discussing this local influence and what might be a good approach to close the gap.

Slide 5 of Attachment B

Keller said this is the original Grand Coulee flow duration curve for the spring timeframe, created using the data shown on slide 4. He said the red line represents the 10th and 90th percentiles. He said the upper bound of the curve is at about 205,000 cubic feet per second (205 kcfs) and the lower bounds is at about 100.5 kcfs.

Keller said the HCPs also include language about what can be done if a survival study falls within the 5% to 10% range and 90% to 95% range of the flow duration curve. He said if this occurs, the HCPs stipulate that the HCP Coordinating Committees are to rule whether to accept the study as valid and the ruling is not subject to dispute. Ferguson said this is another reason to use contemporary data.

Slides 6 and 7 of Attachment B

Keller said these slides show the original flow duration curve data table and graphed curve for the summer timeframe. He said the upper bound is at approximately 165 kcfs and lower bound is approximately 76 kcfs. He said something interesting to note about this dataset is the date range includes July 1 to August 15. He asked, if this dataset was meant to be applicable to subyearling survival studies, what about June? He said it is known that a large portion of hatchery subyearlings and some wild subyearlings arrive at the projects in June.

Slide 8 of Attachment B

Keller recalled in 2013, the HCP Coordinating Committees started discussing updating the curves. He said the HCP Coordinating Committees asked Chelan PUD to do two things with the original spring flow duration curve: 1) add 2002 to 2012 river flow data and identify new 10th and 90th percentiles; and 2) create a new curve using only 1983 to 2012 river flows, eliminating all HYDSIM modeled river flow from the curve.

Slides 9 and 10 of Attachment B

Keller said these are the updated spring curves, per the HCP Coordinating Committees requests in 2013. He said the curve with HYDSIM modeled flows included (slide 9) increased at the upper bound (from 205 kcfs to 296 kcfs) and at the lower bound, but not as much (from 100.5 kcfs to 103 kcfs). He said the curve with HYDSIM modeled data eliminated (slide 10) decreased at both ends (205 kcfs down to 181.6 kcfs and 100.5 kcfs down to 90 kcfs).

Jim Craig asked why not include data through 2018? Keller said these curves only address the requests made by the HCP Coordinating Committees in 2013. He said curves have been developed that include data through 2019, which will be presented in later slides.

Slide 11 of Attachment B

Keller said this slide shows the requests made by the HCP Coordinating Committees in 2013, for the original summer flow duration curve: 1) add 2002 to 2012 river flow data and identify new 10th and 90th percentiles; 2) create a new curve using only 1983 to 2012 river flows, which again, eliminates all HYDSIM modeled river flow from this curve; and 3) repeat the first two updates but include June river flows in the dataset.

Slides 12, 13, 14, and 15 of Attachment B

Keller said slide 12 shows the updated summer curve with HYDSIM modeled data, which increased at both ends (from 165 kcfs to 170.5 kcfs and 76 kcfs to 79.5 kcfs). He said slide 13 shows the same curve with June data, which increased quite a bit on both ends (from 165 kcfs to 290.7 kcfs and 76 kcfs to 104 kcfs). He said slide 14 shows the updated summer curve with no HYDSIM modeled data and no June data. He said this curve decreased at both ends (from 165 kcfs to 157 kcfs and 76 kcfs to 72.7 kcfs). He said slide 15 shows the updated summer curve with no HYDSIM modeled data but with June data. He said this curve increased at both ends (from 165 kcfs to 194 kcfs and 76 kcfs to 78.6 kcfs).

Keller said the slides to this point bring everyone up to speed on the 2013 requests.

Slide 16 of Attachment B

Keller said given how this topic was left in 2013, now would be the time for the HCP Coordinating Committees to choose the best representative Grand Coulee flow duration dataset. He asked if the modeled data should be included or not and should the summer dataset include June or not?

Keller said then Douglas PUD proposed considering project-specific curves that factor in localized snowpack or droughts.

Slide 17 of Attachment B

Keller said that he and Kahler started by compiling local flow data for the Wells, Rocky Reach, and Rock Island projects. Keller said how Grand Coulee Dam is operated is often unknown to Douglas and Chelan PUDs. He said, for example, it is unknown when Grand Coulee Dam is planning a hard draft and implementing reservoir constraints of Lake Roosevelt for drum gate maintenance. He said having a project-specific dataset will eliminate this uncertainty from the curves.

Murdoch said it seems what matters is that river flows are in the middle 80th percentile, and she asked if Chelan PUD or Douglas PUD conducted any analyses to determine how well-correlated project-specific curves are with the middle 80th percentile compared to the Grand Coulee curves. She asked if there are any examples where the Grand Coulee curves are within the middle 80th percentile and the project-specific curves are not. Keller said the overall summaries for the Rock Island Project, which include side flows from the Okanogan, Methow, Entiat, and Wenatchee rivers, showed an increased middle 80th percentile in some years. He said there were also years where the lower bounds did not differ much, but the upper bounds did, or vice versa.

Slide 18 of Attachment B

Keller said this is a new project-specific curve he constructed for the spring timeframe for the Rocky Reach Project using a 1990 to 2019 dataset, where the curve is based on a 30-data set. Keller said moving forward, using a rolling 30-year flow duration curve is something Chelan PUD and Douglas PUD hoped the HCP Coordinating Committees would consider. He said, for example, come 2029, the flow duration curves would add the most recent 10 years of data and the oldest 10 years of data would be removed. He said the curve based on 1990 to 2019 includes an upper bound of 223 kcfs and a lower bound of 104.5 kcfs. He said for a 30-year curve, two data points are outside the 10th to 90th percentiles and fall in the 0 to 10th percentiles and three data points fall in the 90th to 100th percentiles.

Ferguson asked if Keller can explain more about the selection of a 30-year curve versus, for example, a 40-year curve. Keller said considering how project operations have evolved in the upper Columbia River over the past 30 years, he believes 1990 is a good starting point. He said this results in a data set that is large enough to provide stable curves while incorporating flow variability among years but is not too large of a dataset and it relies on the most recent data. He said he likes the idea of maintaining a rolling 30-year curve to account for unforeseen changes in the Columbia River system. He said, for example, the Columbia River Treaty is not yet finalized, and climate change may have effects on river flow. Kahler said Chelan PUD and Douglas PUD also discussed decadal cycles. He said including only one or two decades did not seem adequate but including three decades provides variability by encompassing a broader range. He said the idea is to study representative conditions, and if the dataset is too compressed there is a higher likelihood conditions will fall outside the bounds. He said, conversely, if the dataset is too large this will not capture conditions happening right now. He said a rolling 30-year dataset will also help account for changes in climate over time.

Slide 19 of Attachment B

Keller said this is the summer curve for the Rocky Reach Project using the same 1990 to 2019 dataset. He noted that this curve already includes the month of June and a summer curve without June has not yet been developed. He said he figured the HCP Coordinating Committees would want June included and Chelan PUD believes if a subyearling study will be conducted one day, it could most likely start in the month of June.

Truscott asked why June 1 versus June 15 is used to start the summer timeframe. He asked, looking at the bypass data, what percentage of subyearlings pass early versus late. Keller said the percentages change annually; however, there is typically a pulse of hatchery fish that occurs early. He said shifting to June 15 would exclude these fish that annually migrate past the projects prior to June 15 and annually make up a considerable portion of the juvenile subyearling outmigration. Kahler said additionally, the spring timeframe includes April 16 to May 31, and it makes sense for the summer timeframe to follow right after, which it does by using June 1. Ferguson said if June 15 is used versus June 1, the upper bounds might change from 221 kcfs to 220 kcfs. Keller agreed and said the upper bounds would change but the lower bounds would not.

Slide 20 of Attachment B

Keller said this is the new spring curve for the Rock Island Project, which includes influence from the Wenatchee River. He said the upper bound did not change from the Rocky Reach Project, but the lower bound increased from 104.5 kcfs for the Rocky Reach Project to 111.7 kcfs for the Rock Island Project. He said this is an example of how project-specific curves can capture local influences.

Slide 21 of Attachment B

Keller said this is the new summer curve for the Rock Island Project. *(Note: the screen projection was not functioning properly, but the upper and lower bounds increased slightly compared to the Rocky Reach Project.)*

Slide 22 of Attachment B

Keller said this is the summer curve for the Wells Project using the same 30-year, 1990 to 2019, dataset and including the month of June. He said the upper bound is 215 kcfs and the lower bound is 101 kcfs.

Slide 23 of Attachment B

Keller said this is the new spring curve for the Wells Project.

Keller noted that there are different approaches to constructing flow duration curves. He said both Chelan PUD and Douglas PUD chose to use the average flows across a timeframe, rank the flows from highest to lowest, and draw a line at the 10th and 90th percentiles (i.e., these curves are not smoothed out).

Slide 24 of Attachment B

Keller said this is a second spring curve for the Wells Project. Kahler said he decided to create a second spring curve with an earlier start date of April 13 to encompass the start date of the scheduled 2020 survival verification study at the Wells Project (the Chelan PUD spring curves and first Wells Project spring curve use April 16 as the start date). He said the upper bound is basically the same and noted this should be reported as 218,218 cfs (not 218,480 cfs as shown). He said the lower bound decreases by about 1,400 cfs.

Discussion

Keller said Chelan PUD and Douglas PUD are interested in hearing what the HCP Coordinating Committees think about: 1) switching from the Grand Coulee flow duration curves to project-specific curves for the Wells, Rocky Reach, and Rock Island projects; 2) using a rolling 30-year dataset approach where in 10 years from now the most recent 10 years of data are added and the oldest 10 years of data are removed; and 3) including the month of June in the summer flow duration curves, since this is not stipulated in the HCPs.

Murdoch asked how project-specific curves would work for Chelan PUD where there might be slightly different curves for the Rock Island and Rocky Reach projects, but the survival study encompasses both projects. Keller said Chelan PUD conducts separate survival studies for each project, and he noted that Grant PUD combines projects.

Murdoch said her initial thought is project-specific curves seem the most logical; however, she also wonders what the authors of the HCPs were thinking when choosing to use Grand Coulee Dam for the flow duration curves. She asked if the goal was to find an average for the Columbia River as a whole, or to get at latent mortality, or something else? Ferguson suggested that Murdoch ask Steve Parker and Scott Carlon ask Ritchie Graves. Keller agreed the authors must have thought this through. Truscott said it may have been based on the duration of the dataset. Keller said Grand Coulee Dam does regulate overall flow in the Columbia River. Murdoch said, however, river flow is captured in the project-specific flows, and she asked how long it takes for water passing Grand Coulee Dam to reach Chelan PUD projects. Keller said he is unsure, but project-specific curves essentially true this up.

Murdoch said Chelan PUD and Douglas PUD make good points about the Columbia River Basin treaties and their potential influence on future river flows. Keller added that using a 30-year dataset will also preserve the data from the recent past. Truscott noted in most recent years, the mid-Columbia River has experienced a more rain-dominate freshet than a snow-dominate freshet.

Ferguson said the HCP Coordinating Committees are being asked to consider three topics, which involves changing what is stipulated in the HCPs, and, therefore, will necessitate one or possibly three SOAs. Truscott said he also sees a fourth topic, which is what constitutes normal flows for study validation. He said in his mind, normal river flow can be the timing of flow within each spring and summer timeframe. He said what if there is low or high river flow in early or late parts of each timeframe, but the study plan is based on average run-timing curves. He asked how to synchronize these together. He asked if river flow can be considered more finely than over a month-and-a-half timeframe. Keller said the flow duration curves are developed to be applicable to the best estimated time to conduct a survival study. He said when Chelan PUD conducted a survival study for yearling Chinook salmon in the Rocky Reach Project, fish were arriving early and with increased consistency before the start of the survival study. He said still, Chelan PUD waited to have high certainty there would be no gaps in meeting the tag quotas required for release replicates, and once the study started, that fish would continue arriving consistently for 30 to 35 days to tag the most representative run as possible. He said Chelan PUD believes this approach worked well based on a review of the Columbia River Data Access in Real Time database (DART). Truscott asked if river flow in the last 2 weeks in April was outside the 10th to 90th percentile range. Murdoch asked Truscott to clarify what he is asking, and Truscott said he is wondering if it is possible to consider river flows in smaller increments. Keller said he believes should river flows fall outside the 10th to 90th percentile, when examined on smaller increments, those flows would be incorporated into the evaluation of survival estimates, and the average project flow for the study would be compared to the respective flow duration curve. Kahler said the Douglas PUD 2010 survival study started with low river flows and a freshet did not occur until maybe about the third week into the study. He said right before starting the test, Douglas PUD came to the Wells HCP Coordinating Committee and asked if the study should go on because there was no freshet. He said the Wells HCP Coordinating Committee said to do it. Ferguson reminded the HCP Coordinating Committees about the 5th to 95th percentile range Keller had mentioned earlier, as also written in the HCPs (slide 5 of Attachment B). Ferguson said it seems there is a post-hoc interpretation of data where the HCP Coordinating Committees evaluate whether the study occurred in representative conditions and can be accepted as valid. Keller said given the curves are an average, it is expected that river flows could be above or below the curve at times when analyzed on a weekly or daily interval. He said this is expected with survival studies and the study plans are tailored to accommodate this.

Murdoch said regarding the SOAs, changing what is stipulated in the HCPs does raise a red flag for the Yakama Nation (YN). She recalled a couple of years ago, the YN made a strong position with Grant PUD that a higher level of attention is needed than just an SOA at the technical level to change what is written in the Salmon and Steelhead Settlement Agreement. She said this may just involve a discussion with policy staff and creative language in the SOA with an expiration date so as to not permanently change the HCPs, but something more needs to be done. Keller said a 10-year expiration date would be appropriate since the curves need to be revisited every 10 years anyway. Kahler clarified that the Chelan PUD HCPs stipulate the curves will change, and the Wells HCP only stipulates the curves are subject to periodic review. Keller read from Section 13.24 of the Rock Island HCP:

> *"Starting as part of the 2013 comprehensive review, and every ten years thereafter, the Coordinating Committee shall update the flow duration curve and the river flow amounts contained in this definition."*

Therefore, the proposed considerations (and associated SOAs) will not change the language in the HCPs.

Truscott asked about the turbine hydraulic capacity at Rocky Reach Dam. Keller said under normal operations the capacity is about 208 to 210 kcfs. Truscott said if river flow exceeds the powerhouse capacity, involuntary spill might improve survival and then this number would be used for the next 10 years and into mitigation. Keller said Chelan PUD uses acoustic tags for survival studies so the last route of detection is known and fish passing via the spillway can be removed from the analysis. Truscott said Douglas PUD does not use acoustic tags, and he asked how the Wells Project accounts for improved survival from an anomalous year. Ferguson said this is addressed by the flow duration curve and the study fitting within the 10th to 90th percentile. Kahler said that Wells Dam has typically been a nine-unit plant and the hydraulic capacity is always under 180 kcfs. He said he recalls no involuntary spill during the survival study in 2010 under flow conditions that year, and although flow was low, it fit inside the flow duration curve, so the study was accepted. He added that this is just one data point on a multi-year average. Truscott said the same can be said on the lower bounds. He said a low flow year might have poorer survival. Keller said 2019 is on pace to be the third lowest water year since Rocky Reach Dam was constructed.

Keller reiterated Chelan PUD's proposal: 1) use project-specific curves for the Wells, Rocky Reach, and Rock Island projects; 2) use a rolling 30-year dataset; and 3) include June in the flow duration curve for the summer timeframe. Kahler said Douglas PUD is proposing the same.

Ferguson said the PUDs will bring WDFW up to speed on this topic prior to the December meeting. He asked that the HCP Coordinating Committees representatives think about this information and expect SOAs for approval during the HCP Coordinating Committees meeting on December 17, 2019.

The draft SOA, *Regarding the Updated Flow-Duration Curves for the Wells Hydroelectric Project For Establishing Representative Environmental Conditions*, was distributed to the HCP Coordinating Committees by Geris on December 5, 2019; and the draft SOAs, *Updated Flow Duration Curves for the Rock Island Project for Establishing Representative Flow Conditions* and *Updated Flow Duration Curves* *for the Rocky Reach Project for Establishing Representative Flow Conditions*, were distributed to the HCP Coordinating Committees by Geris on December 6, 2019.

IV. Chelan PUD

A. DECISION: Northern Pikeminnow Predator Control Program, Rocky Reach and Rock Island Hydroelectric Projects, Draft Summary Report, 2018 (Lance Keller)

Lance Keller said the *Northern Pikeminnow Predator Control Program, Rocky Reach and Rock Island Hydroelectric Projects, Draft Summary Report, 2018* was distributed to the HCP Coordinating Committees by Kristi Geris on September 10, 2019 and was available for a 30-day review with edits and comments due to Keller by October 10, 2019. Keller said no comments were received on the draft 2018 report. He said the draft 2019 report will be distributed to the HCP Coordinating Committees for review in early 2020. Keely Murdoch asked if any new data have surfaced that might suggest a change in approach for the program in future years. Keller said no, and so far these reports have shown no increase in fish encounters or fish size, which is good news. He said this effort includes angling using rod and reel and setlines, boat crews, deck crews, and input from the community via a fishing derby.

Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the *Northern Pikeminnow Predator Control Program, Rocky Reach and Rock Island Hydroelectric Projects, Draft Summary Report, 2018*. *(Chad Jackson provided WDFW approval of the draft report via email on November 12, 2019.)*

B. 2019 Rocky Reach and Rock Island Fish Spill Report (Lance Keller)

Lance Keller said the *Chelan PUD Rocky Reach and Rock Island HCPs Draft 2019 Fish Spill Report* (Attachment C) was distributed to the HCP Coordinating Committees by Kristi Geris prior to the HCP Coordinating Committees meeting on November 19, 2019. Keller said the report is in the same format as last year. He recalled that Thad Mosey (Chelan PUD) typically presents this report; however, he is unavailable today.

Keller said Rocky Reach Dam does not have a spring spill requirement. He said for summer spill at Rocky Reach Dam, the target species is subyearling Chinook salmon, with a summer spill target of 9% of the daily average river flow. He said spill was initiated on June 2 and terminated on August 12, 2019. He said Program RealTime estimated that 95% passage was achieved on July 28, 2019. He said retrospectively looking at Program RealTime for run coverage, 99.1% of the run was covered by August 12, 2019. He said the cumulative index count was 33,299 subyearlings over Rocky Reach Dam (as of August 31, 2019). Keller said Mosey did a good job on summer fish spill, hitting a spill percentage of 9.09%. Keller said of this fish spill, 0.07% was forced spill. He said average river flow at

Rocky Reach Dam was 100,417 cfs, average spill was 9,131 cfs, and there were 72 total days of spill. He said the graph for summer spill at Rocky Reach Dam shows a blue line for the daily index counts at the Rocky Reach Juvenile Sampling Facility (RRJSF) and a red line for percent spill for that day. He noted that the percent spill varies a bit, and he said this is affected by estimated outflow from Chief Joseph Dam and Grand Coulee Dam discharge. He explained that Chelan PUD must submit fish spill requests 2 to 5 days in advance and sometimes this estimate from Chief Joseph Dam changes. He said during a low flow year (such as 2019), an inaccurate flow estimate of 5 kcfs can result in a big difference. Keller said Mosey tracks how accurate the estimates are and bases his spill requests off of this. Keller said Mosey did a good job of maintaining spill volume across this time period. Keller said the graph on page 2 of Attachment C is the graph the HCP Coordinating Committees requested to be added to these spill reports. He said this graph shows, of the daily index counts at the RRJSF, what proportion of subyearlings are adipose (ad)-present. He said initially, hatchery fish dominated and there were very few ad-present fish, until the end of June 2019, and then ad-present fish dominated.

Keller said at Rock Island Dam, the spring spill target species include yearling Chinook salmon, steelhead, and sockeye salmon. He said the spring spill target is 10% of the daily average river flow. He said in 2019, the fish runs were late, and spill did not start until April 17, 2019, at 0001 hours, which is the deadline to start spring spill as stipulated in the Rock Island HCP. Keller said Mosey monitors the fish counts very carefully and there were minimal counts prior to April 17, 2019. Keller said on June 1, 2019, operators switched from 10% spring spill to 20% summer spill instantaneously. He said retrospectively looking at run coverage, spring and summer fish spill operations combined covered 99.7% of the yearling run, 99.9% of the steelhead run, and 98.5% of the sockeye salmon run. He said coverage for each species exceeded the 95% coverage target outlined in the Rock Island HCP. He said the cumulative index counts as of August 31, 2019, included 18,855 yearling Chinook salmon, 9,881 steelhead, and 7,416 sockeye salmon. He said the spring spill percentage from April 17 to June 1, 2019, was 11.67% including 10.03% requested fish spill and 1.64% forced spill beyond project capacity. He said the average river flow for the spring spill period was 128,137 cfs and average spill was 14,948 cfs. He said there were a total of 46 spill days. He described the color-coding of the graph for spring spill at Rock Island Dam and noted that the sockeye salmon run exhibited bimodal (and almost trimodal) peaks. Keely Murdoch asked if this might represent Osoyoos River versus Wenatchee River populations? Keller said he believes so, and there is a size difference between the two stocks and Wenatchee River sockeye salmon arrive earlier. He said in the past, spill has been initiated earlier due to Wenatchee River sockeye salmon arriving early.

Keller said for summer spill at Rock Island Dam, the target species is subyearlings with a goal of 20% spill of the daily average river flow. He said summer spill started on June 2 and was an instantaneous increase from 10% spring spill. He said summer spill ended at Rock Island Dam on August 19, 2019, at 2400 hours. He said Program RealTime estimated 95% passage was achieved on August 3, 2019.

He said as of August 19, 2019, spill operations covered 98.5% of the subyearling run. He said the cumulative index count was 11,876 subyearlings, and the summer spill percentage was 20.13% including 19.90% requested spill and 0.23% forced spill. He said average river flow was 101,744 cfs, average spill was 20,482 cfs, and then there is another graph for summer spill similar to Rocky Reach Dam. He said page 5 of Attachment C shows the subyearling ad-present proportions for Rock Island Dam. Murdoch asked why yearling Chinook salmon were not included on these ad-present graphs and Keller said because the HCP Coordinating Committees did not request to include yearlings on these graphs. Keller recalled that incorporating these graphs for subyearlings was a request from Kirk Truscott. Murdoch said she is particularly interested in the wild yearling spring Chinook salmon run coinciding with spill operations. Keller said Chelan PUD can add yearlings to these graphs. Murdoch said this is not necessary, she just wonders what proportion of wild versus hatchery springers are being covered by fish spill operations. She said the springers arriving early are likely wild but not in high enough numbers to trigger fish spill operations. Keller said Chelan PUD has records of which fish are ad-present or clipped; however, initiation of spill is based on species counts not origin counts. He added that one would need to make broad assumptions to attempt to get at Murdoch's question.

John Ferguson asked Murdoch how she would like to move forward and Murdoch suggested continuing discussing this topic within the HCP Coordinating Committees. Murdoch said understanding the idea is to protect fish with spill operations, she asked if the spill dates are adequate to protect wild spring Chinook salmon. Keller said this is hard to determine, but Chelan PUD does implement a spill program that was in use when phase designation survival studies were conducted and survival standards were achieved for Plan Species, and these were representative of both wild- and hatchery-origin juveniles. Ferguson summarized that Chelan PUD is operating in compliance with the HCPs and past survival studies but is there more information about wild springers that could be brought forward. Murdoch said she understands the HCPs focus on protecting what is in the river, which includes hatchery fish, but at the same time, it would be good to get at recovery. Truscott said one could determine a rough estimate of natural-origin fish through the process of elimination. He suggested examining yearling Chinook salmon for ad-clipped, coded wire tags, or passive integrated transponder (PIT) tags. He said some natural-origin fish may have a PIT tag from the screw traps, so this would require checking the tag codes against those data. Keller asked, however, if these data would change when spill is either turned on or off? He said the passage rate of juveniles at Powerhouse 2 most likely changes once spill is initiated since an additional passage route adjacent to Powerhouse 2 is now available, and the collection efficiency of the Powerhouse 2 bypass trap most likely changes as well and could compromise the ability to compare counts before and after the initiation of the spring fish spill program. He said downstream PIT detections cannot be used as neither the passage date nor the route of passage at Rock Island Dam is known unless the fish passed via the Powerhouse 2 bypass trap.

Keller said page 6 of Attachment C summarizes the historical counts at Rocky Reach Dam and Rock Island Dam. He noted that sampling efficiency at the two locations are different, and are therefore, not directly comparable.

Chelan PUD will request approval of the *Chelan PUD Rocky Reach and Rock Island HCPs Draft 2019 Fish Spill Report* during the HCP Coordinating Committees meeting on December 17, 2019.

C. Rocky Reach Dam Turbine Unit C1 and C3 Update (Lance Keller)

Lance Keller said mechanical staff are still waiting for parts for Turbine Unit C1 and with continued delays in recommissioning Turbine Unit C9, both schedules have been moved back. He said the return-to-service dates for Turbine Units C1 and C9 are now January 2020 and February 2020, respectively.

Keller said in October 2019, Turbine Unit C3 was taken offline for a 1-month check-up and mechanics discovered additional oil had been released from the unit. He said new seals were installed, the seals passed initial testing, and the unit was returned to service on October 11, 2019. He said when Turbine Unit C3 tailrace stoplogs were removed, mechanics observed small traces of oil in the tailrace and thought this was residual oil remaining from the unit work. He said mechanics took Turbine Unit C3 offline again, but the unit did not appear to be the source of the oil leak. He said Turbine Unit C2 was out-of-service that same morning to facilitate divers' cleaning of trashracks and then brought back online that same day. He said mechanics took Turbine Unit C2 offline again and observed oil in the tailrace; therefore, mechanics believe there is an issue with Turbine Unit C2, as well. Keller said mechanics believe trunnion seals are not the issue with Turbine Unit C2; rather, it may be a failure of the internal servo rod seal that allows the blade to change pitch. He said if this seal fails it can cause over-pressurization of the turbine hub. He said, however, mechanics had not yet been able to get into Turbine Unit C2 to investigate the issue because all of the crews and headgates were in use for Turbine Units C1 (repairs), C3 (seals), C7 (vibration issues), and C9 (repairs). He said since this time, additional testing was performed on Turbine Unit C3 to evaluate the internal servo rod seal, which the seals passed, and after about a 1-month outage, Turbine Unit C3 was finally returned to service on November 18, 2019. He said mechanics are performing daily monitoring of oil in Turbine Unit C3 with the understanding that if a fluctuation is observed the unit will be taken out of service.

Keller said Natural Resource staff are encouraging the mechanical staff to maintain the Turbine Unit C1 return-to-service date of February 2020, prior to the Rocky Reach Juvenile Fish Bypass System starting operations. He said the small units, Turbine Units C1 to C7, are designed the same with the same internal servo rod seals in all of them, as well as the same trunnion seals. He said the plan is to analyze these parts across the entire range of small units. He said Chelan PUD is also still working with the external consulting firm from Italy on developing a plan for block-loading the unit and operating it in this manner if needed in the future. He said Turbine Unit C2 will be out-of-service until headgates and crews become available and are able to assess the unit further. He said these headgates are the same gates used to isolate the attraction water to dewater the adult fish ladders for annual winter maintenance, which is scheduled to start in mid-December as approved by the Rocky Reach HCP Coordinating Committees (on August 27, 2019).

D. Rock Island Dam Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said work continues to move forward on Turbine Unit B4. He recalled that Turbine Unit B4 is the first original small unit to be refurbished in Powerhouse 1. He said delays in the schedule have been caused by discovering that some parts were beyond refurbishment and needed replacement and delays in receiving the replacement parts. He said the original return-to-service date of early December 2019 has been updated to May 2020. He said Turbine Unit B4 is the first look into these original units and hopefully efficiencies can be gained and implemented on the remaining three units.

V. Douglas PUD

A. 2019 Wells Dam Post-Season Bypass Report and Passage-Dates Analysis (Tom Kahler)

Tom Kahler said the Passage-Dates Analysis portion of the 2019 Wells Dam Post-Season Bypass Report was distributed to the HCP Coordinating Committees by Kristi Geris prior to the HCP Coordinating Committees meeting on November 19, 2019. Kahler clarified that the Passage-Dates Analysis addresses how the Wells Project performed in terms of meeting compliance (i.e., the results), and the cover sheet to this document (or 2019 Wells Dam Post-Season Bypass Report) describes what operations were implemented during the year (e.g., when bypass barriers were pulled). Kahler said the results were distributed but the cover page is still undergoing internal review. *(Note: the 2019 Wells Dam Post-Season Bypass Report was distributed to the HCP Coordinating Committees by Geris on December 5, 2019.)*

Kahler said the Passage-Dates Analysis has been presented in the same format since 2011. He said a comparison of wild Chinook salmon was added in the last couple of years and then applied retrospectively back to 2012. He said one thing that is different this year is there were enough data to true up travel times. He recalled in past reports, mean travel times from the 2010 survival study were used to estimate passage dates. He said this year, travel times for steelhead, yearling Chinook salmon, and coho salmon were estimated using detections of fish that were PIT-tagged above Wells Dam and detected at both Wells and Rocky Reach dams. He said travel times for sockeye salmon were estimated using Chelan PUD acoustic tag study results of fish released in the Wells Dam tailrace and detected at Rocky Reach Dam. He said for subyearling Chinook salmon, there were too few detections at Wells and Rocky Reach dams; therefore, travel time for subyearlings was calculated by taking all subyearlings released above Wells Dam and detected at Rocky Reach Dam from 2011 to 2019 and splitting this travel time in half. He said travel times for steelhead, yearling Chinook salmon, coho and sockeye salmon, and subyearling Chinook salmon are presented in the appendix to the Passage-Dates Analysis.

Kahler said compliance in 2019 was good for both hatchery and wild fish. He said there was a late freshet this year and associated late movement of wild subyearling and yearling Chinook salmon, which aligned more closely with movement of the respective hatchery components compared to other years. He said Wells Dam bypass operations in 2019 provided 100% coverage for each Plan Species migration, except for coho salmon, which had 99.99% coverage. He noted that bypass operations were shut down several days after already achieving 95% passage for both hatchery and wild subyearling Chinook salmon. He said the closest this has been is 10 days after achieving 95% and has been as many as 35 days after. He noted for wild yearling Chinook salmon, bypass operations were initiated 6 days before 5% of the run passed Wells Dam. He said 2019 was a good year for fish passage at Wells Dam regardless of origin.

Kahler asked that the HCP Coordinating Committees contact him with questions. Douglas PUD will request approval of the 2019 Wells Dam Post-Season Bypass Report and Passage-Dates Analysis during the HCP Coordinating Committees meeting on December 17, 2019.

B. DECISION: Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019 (Tom Kahler)

Tom Kahler recalled that a *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019* was distributed to the HCP Coordinating Committees by Kahler during the HCP Coordinating Committees meeting on September 24, 2019. Kahler said he received comments during the meeting, addressed these in the draft document, and a revised draft document was distributed to the HCP Coordinating Committees by Kristi Geris following the HCP Coordinating Committees meeting on September 24, 2019. Geris recalled that the Wells HCP Coordinating Committee had an action item to review the revised draft document and be prepared to discuss a path forward during the HCP Coordinating Committees meeting on October 22, 2019, which was canceled.

Wells HCP Coordinating Committees representatives present approved the *Draft Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019*, as revised. Anchor QEA, LLC, will contact Chad Jackson regarding WDFW approval of the revised draft document. *(Note: Geris emailed Jackson on November 20, 2019, with this request and Jackson provided WDFW approval of the document via email on November 22, 2019.)*

The final *Estimates of Additional Mortality Resulting from Non-Compliant Bypass Operations at Wells Dam During April 2019* was distributed to the HCP Coordinating Committees by Geris on November 22, 2019.

VI. HCP Administration

A. Final HCP Policy Committees July 9, 2019 Meeting Minutes (John Ferguson)

John Ferguson said the HCP Policy Committees approved the HCP Policy Committees July 9, 2019 meeting minutes, as revised. Kristi Geris added that the minutes were approved via email on September 25, 2019. Geris said the final minutes were distributed to each HCP Committee and Larissa Rohrbach (HCP Hatchery Committees Support Staff) incorporated the HCP Policy Committees guidance about funding criteria into the HCP Hatchery Committees protocols (i.e., to base funding decisions on technical merit, and notify respective HCP Policy Committees and HCP Coordinating Committees of any potential policy issues needing to be addressed in those forums). *(Note: The guidance from the HCP Policy Committees is also captured in the HCP Tributary Committees July 16, 2019 meeting minutes, the 2019 HCP annual reports, and in the HCP Tributary Committees' Operating Procedures)*.

B. Next Meetings (John Ferguson)

The next scheduled HCP Coordinating Committees meeting is on December 17, 2019, to be held at 9:00 a.m. (instead of 10:00 a.m.), in-person at the Grant PUD Wenatchee office in Wenatchee, Washington.

The January 28 and February 25, 2020 meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

Update

Representative Survival Study Flows

HCP Valid Studies

"A valid study is one in which the study design, implementation, and criteria are determined to have been met by the Coordinating Committee, and one in which the study took place during Representative Flow Conditions and normal project operating conditions consistent with the approved study design."

“Representative Flow Conditions”

- Representative survival study flows bound the 10th percentile mean flow and the 90th percentile mean flow from Grand Coulee Dam (GCL) during the HCP survival study periods for spring and summer.

- Measured as mean daily out-flows from GCL during the spring and summer juvenile Plan Species study periods.

- HCP Spring Study Period: 16 April to 31 May

- HCP Summer Study Period: 1 July to 15 August

- HCP: “Update flow duration curves every 10 years with new flow data from GCL”

HCP CC 2013:
Evaluate Spring Study Flows for Two Scenarios

1) Update the original flow duration curves by adding 2002-2012 flows, identify the new 10th and 90th percentile flows (HCPs 13.24 Appendix C, page 39).

2) Create new flow duration curves using *only* 1983 to 2012 flows, identify the new 10th and 90th percentile flows.

HCP CC 2013:
Evaluate Summer Study Flows for Four Scenarios

1) Update the flow duration curves by *adding* GCL flows from 2002-2012 to existing GCL flow data, identify the new 10^{th} and 90^{th} percentile flows (HCPs 13.24 Appendix C, page 39).

2) Create new flow duration curves using *only* GCL flows from 1983 to 2012, identify the new 10^{th} and 90^{th} percentile flows.

3) Re-evaluate the first two scenarios with 1983-2012 *June flows* in the flow data sets, identify the 10^{th} and 90^{th} percentile flows for both scenarios.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: February 22, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the January 16, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCP) Hatchery Committees (HC) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held on Wednesday, January 16, 2019, from 9:00 a.m. to 1:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Tracy Hillman will review aspects of the Independent Scientific Advisory Board's *Review of Spring Chinook Salmon in the Upper Columbia River* under HCP-HCs' purview (Item I-A). *(Note: this item is ongoing)*
- Greg Mackey will continue researching whether to include age-3 males in broodstock and discuss it with Craig Busack (National Marine Fisheries Service [NMFS]; Item I-A). *(Note: this item is ongoing.)*
- Keely Murdoch will attempt to provide coho salmon broodstock collection protocols to Mike Tonseth by early February for inclusion in the draft 2019 Broodstock Collection Protocols (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) regarding presenting pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing.)*
- Keely Murdoch will research past co-mingling ratios of coho salmon to spring Chinook salmon at Winthrop National Fish Hatchery or other locations (Item I-A). *(Note: this item is ongoing.)*
- Larissa Rohrbach will obtain approval or abstention from NMFS to approve the December 2018 meeting minutes (Item I-A). *(Note: NMFS did not respond to a request for a vote within 5 business days and therefore abstained. Brett Farman [NMFS] approved via email on February 13, 2019)*

- Larissa Rohrbach will schedule a tentative conference call on March 11, 2019, at 2:30 pm for the HCP-HC and PRCC HSC to discuss the draft 2019 Broodstock Collection Protocols (Item I-A). *(Note: Rohrbach sent a calendar placeholder via email on January 28, 2019)*
- Catherine Willard will update the genetics section of the *Monitoring and Evaluation Plan for PUD Hatchery Programs (update to the 2017 Plan)* based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item II-A)
- Mike Tonseth will share draft 2019 Broodstock Collection Protocols with the HCP-HC and PRCC HSC by February 11 (Item II-B).
- Greg Mackey will confirm with Betsy Bamberger (Douglas PUD) whether Douglas PUD will use the Washington Animal Disease Diagnostic Laboratory (WADDL) for in-season bacterial kidney disease (BKD) testing during 2019 broodstock collection and confirm that WADDL methods will provide ELISA optical density test results (Item II-B).
- Kirk Truscott will discuss with Colville Confederated Tribe (CCT) biologists whether elemental signature analysis in fish scales, fin rays, or otoliths could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item II-B).
- Mike Tonseth will ask Andrew Murdoch for interim pre-spawn mortality data for spring Chinook salmon to incorporate into the 2019 Broodstock Collection Protocols (Item II-B).
- Larissa Rohrbach will add the size of upper Columbia River conservation programs as a periodic agenda item (Item II-C). *(Note: this item is ongoing)*
- Mike Tonseth will ask Andrew Murdoch to provide to the PUDs a list of passive integrated transponder (PIT)-tag arrays that will be shut down if not funded, the cost to operate and maintain these arrays, and the cost of PIT tagging steelhead at the Priest Rapids Dam Off-Ladder Adult Fish Trap (OLAFT; Item II-D)
- Larissa Rohrbach will draft email distribution lists merging HCP-HC and PRCC HSC recipients for review and approval by the HCP-HC and PRCC HSC and the HCP Coordinating Committees (Item II-E). (*Note these documents were emailed by Rohrbach to the HCP-HC and PRCC HSC on February 7, 2019)*
- Larissa Rohrbach and Tracy Hillman will revise and distribute meeting protocols for the HCP-HC and PRCC HSC for review and approval (Item II-E). (*Note these documents were emailed by Rohrbach to the HCP-HC and PRCC HSC on February 7, 2019)*
- Tracy Hillman will send the Statement of Agreement (SOA) regarding conflicts of interest to Larissa Rohrbach for inclusion of language in the meeting protocols (Item II-E). *(Note: The most recent Conflict of Interest Policy, dated January 26, 2013, was emailed by Hillman to Rohrbach on January 17, 2019)*

Wells Hatchery Committee

- Greg Mackey will provide a revised version of Douglas PUD's draft 2019 Monitoring and Evaluation (M&E) Implementation Plan for HCP-HC approval by email (Item III-A).

Decision Summary

- The HCP-HC and PRCC HSC agreed to add analysis of linkage disequilibrium to the Hatchery M&E Plan (update to the 2017 Plan). Chelan PUD, Douglas PUD, Grant PUD, U.S. Fish and Wildlife Service (USFWS), WDFW, CCT, and the Yakama Nation (YN) approved during the meeting on January 16, 2019, and NMFS abstained (Item II-A). *(Note: Brett Farman [NMFS] approved via email on February 13, 2019)*.

Agreements

- The HCP-HC and PRCC HSC agreed to the following items regarding joint meetings:
  - Combine meeting attendance into one forum
  - Issue one meeting agenda (including estimated duration for discussion items) and one set of meeting minutes
  - Develop similar protocols for documentation and distribution of materials in emails, pending agreement to final distribution lists
  - Develop joint meeting protocols
- Chelan PUD, Douglas PUD, Grant PUD, USFWS, WDFW, CCT, and YN approved during the meeting on January 16, 2019, and NMFS abstained (Item II-E). *(Note: Brett Farman [NMFS] approved via email on February 13, 2019)*

Review Items

- Larissa Rohrbach sent an email to the Rocky Reach and Rock Island HCs on January 21, 2019, notifying them that the 2019 Wells HCP Action Plan is available for a 30-day review with edits due to Tom Kahler by February 21, 2019.

Finalized Documents

- No items have been recently finalized.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the December 19, 2018 Meeting Minutes (Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and explained the purpose for changes in the structure of today's agenda. Hillman noted that this will be the first meeting in which the HCP-HCs and PRCC HSC will meet with a single chair/facilitator on the same day. To meet the needs of the newly-formed meeting structure, changes have been made to the format of the agenda including subsections that reflect grouping of agenda items by the names of the committees (i.e., Wells, Rocky Reach, Rock Island, or PRCC HSC) and addressing action items within each subsection of the agenda. These changes will allow different parties to join or leave portions of the meeting that are relevant to their agreements.

Hillman asked for any additions or changes to the agenda. Additions were requested as follows:

- Hillman struck the NMFS consultation update due to lack of NMFS representation at the meeting.
- Sarah Montgomery moved the "Streamlining HCP-HCs and PRCC HSC meetings" discussion from the PRCC HSC section of the agenda to the Joint HCP-HCs/PRCC HSC section of the agenda.
- Catherine Willard added an item to the Rocky Reach and Rock Island HCs regarding an update on Tumwater Dam fishway repairs.

Larissa Rohrbach said there were only editorial or clarifying revisions to the December 19, 2018 meeting minutes and no substantive revisions requiring review by the HCP-HCs and PRCC HSC representatives. Representatives for Douglas PUD, Chelan PUD, Grant PUD, YN, and USFWS approved the December minutes. Representatives from WDFW and CCT abstained. Representatives from NMFS were not present due to the partial federal government shutdown, causing Hillman to delay final approval of the minutes for an additional 5 business days at which time NMFS may respond with their approval via email, or a lack of response will be noted as abstention from voting. If no response is obtained by January 24, 2019, Larissa Rohrbach said she will notify the NMFS representatives via email that the December minutes are approved. Brett Farman (NMFS) approved via email on February 13, 2019.

Action items from the HCP-HC meeting on December 19, 2018, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on December 19, 2018)*:

- *Tracy Hillman will review aspects of the Independent Scientific Advisory Board's Review of Spring Chinook Salmon in the Upper Columbia River under Hatchery Committees' purview (Item I-A).*

  Hillman provided an update on the status of this action item by describing the multiple paired before-after, control-impact (MPBACI) modeling tool, which demonstrates population-level responses to spring Chinook salmon supplementation in paired treatment and control streams. Hillman said the model was built using data from the Coordinated Assessments Data Exchange[1] and other sources from the YN and Nez Perce tribes. He said he is still compiling data and revising the model.

  Hillman showed MPBACI models in his draft spreadsheet "Spring Chinook Stock/Recruit Data for Treatment and Reference Areas," and shared the following:

  - Calculation of before-after, control-impact (BACI) contrasts, which show the magnitude of supplementation effects
  - Graphical analysis of BACI data
  - Preliminary results from different statistical tests including analysis of covariance (ANCOVA), randomization tests, Monte Carlo simulations, simple T-tests using difference scores, and complex, mixed-model analyses of variance (ANOVA) using raw data. The latter includes fixed and random factors with nested and fully crossed factors.
  - A variance table showing the sources of variation that are analyzed using the mixed-model ANOVA model.
  - The advantages of using complex mixed models over simpler models. Hillman developed the complex models in SYSTAT.

  Hillman said he sent the mixed model to Dr. Barb Downes (University of Melbourne) for peer review, and she gave it a positive review. To check the model, Hillman said he ran it using data from both Drs. Downes and Carl Schwarz (Simon Fraser University, retired) and found the model performed correctly.

  Hillman will use this information to update the M&E Plan (update to the 2017 Plan). Greg Mackey asked what the difference is between this method and the previous approach. Hillman said this approach includes comparing a supplemented population with all control

[1] Further information about the Coordinated Assessments Data Exchange can be found at: https://www.streamnet.org/coordinated-assessments-des.

populations using one analysis. Previous plans used separate analyses for each paired treatment and control population. Hillman said he is still troubleshooting the equation for estimating the BACI contrast. In preliminary tests using data in Schwarz, (2015)[2] the equation does not always give the same answer provided by Schwarz. Hillman said when he is finished testing the models, he will make changes in the M&E Plan and pass the document to the HCP-HC and PRCC HSC for review.

- *Greg Mackey will continue researching whether to include age-3 males in broodstock and discuss it with Craig Busack (National Marine Fisheries Service [NMFS]; Item I-A).*
  Mackey reminded the group that the purpose of this task is to determine whether to include jacks in broodstock, and if so, what is the appropriate number or percentage. He said on the pragmatic side in a small program, if the program is short on wild brood, it may be better to use a wild jack versus an older hatchery-origin male. He proposed avoiding a blanket prohibition against using jacks in broodstock collection protocols. Mike Tonseth agreed, considering managers would want to know parental origin of a jack to avoid using progeny of naturally spawning hatchery fish. Mackey agreed but noted that managers would also not want to exclude genetic variability associated with jacks. Keely Murdoch said previous analyses of spring Chinook salmon in the Wenatchee Basin as part of the reproductive success study show a stronger association with females than males. She said for this reason, incorporating age-3 males in the broodstock may not be a major issue. Mackey noted the question is whether early maturation is heritable and whether programs would increase early-maturing males in the hatchery population by including jacks in broodstock, and how that would vary in different years based on frequency-dependent spawning rates. Tonseth said there is a bigger size disparity between jacks and older males in spring Chinook salmon than summer Chinook salmon and suggested that broodstock chosen by size inevitably includes some jacks and excludes some older fish. He suggested that managers review data from previous years to find out if this has happened. Todd Pearsons said there may be some adjustments to the protocols this year to achieve numbers needed due to predicted low abundance. Tonseth confirmed the need to include some age-3 fish due to low projected escapement for 2019. Mackey noted this item is still ongoing and will not be resolved for the 2019 Broodstock Collection Protocols.
- *Keely Murdoch will provide coho salmon broodstock collection protocols to Mike Tonseth by late February or early March 2019 for inclusion in the 2019 Broodstock Collection Protocols (Item I-A).*

---

[2] Schwarz, C.J. 2015. Analysis of BACI experiments. Chapter 12 in course notes for beginning and intermediate statistics. Available at: http://www.stat.sfu.ca/~cschwarz/CourseNotes.

Tracy Hillman suggested that Murdoch provide coho salmon broodstock collection protocols to Mike Tonseth earlier than late February to allow for draft broodstock collection protocols to be distributed 10 days before the February meeting, in line with the SOA specific to PUD programs. Murdoch said this is very early for developing their typical YN coho salmon protocol because coho salmon spawn so late in the year. Murdoch will attempt to provide the protocols in January.

- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) regarding presenting pre-spawn mortality modeling results for spring Chinook salmon at an upcoming Hatchery Committees meeting (Item I-A).*
  Tonseth said additional analysis is needed and the timeline for providing modeling results will be extended because some federal staff involved in the modeling are furloughed due to the partial federal government shutdown.
- *Keely Murdoch will send the conservation program size spreadsheets to the Hatchery Committees (Item I-A).*
  Murdoch provided the 2018 Sliding Scale and Safety Net Update spreadsheet to the HCP-HC via email on January 3, 2019. Murdoch said this action item is complete. This item will be discussed in today's meeting (Item II-B.6).
- *Keely Murdoch will research past co-mingling ratios of coho salmon to spring Chinook salmon at Winthrop National Fish Hatchery or other locations (Item I-A). (Note: this item is ongoing.)*
  Murdoch said this action item is ongoing.
- *Keely Murdoch will provide information about the passive integrated transponder (PIT)-tagging strategy for the coho salmon that will be acclimated at Twisp Pond (Item I-A).*
  Murdoch provided this update via email to the HCP-HC on January 3, 2019. Murdoch said this action item is complete.
- *Sarah Montgomery will obtain approval for the October and November 2018 meeting minutes from NMFS (Item I-A).*
  Montgomery said final versions of the meeting minutes were distributed on December 20, 2018, and this action item is complete.
- *Hatchery Committees representatives will review recommendations provided by the geneticist panel and send any additional questions to Tracy Hillman by January 7, 2019 (Item II-A).*
  Hillman said he received no feedback. All HCP-HC and PRCC HSC representatives agreed that information provided was sufficient. Hillman said he will follow up with geneticists to finalize the feedback. This item will be discussed in today's meeting (Item II-A).
- *Sarah Montgomery and Tracy Hillman will compile potential March 2019 conference call dates and send a poll to the Hatchery Committees representatives (Item IV-A).*

Montgomery sent the poll following the meeting on December 19, 2018, requesting feedback by January 4, 2019. Montgomery asked the representatives which date is best for an optional conference call to discuss broodstock collection protocols. She said the goal is to resolve changes to the protocols prior to the March 20, 2019 meeting. All representatives agreed to set a placeholder for a conference call on Monday, March 11, 2019, at 2:30 pm. Larissa Rohrbach said she will send a meeting invitation.

II. Joint HCP-HCs and PRCC HSC

A. Genetic Monitoring (Tracy Hillman)

Tracy Hillman reminded the committees that they received recommendations from the geneticist panel on December 10, 2018, in a document titled, *Response to questions posed by the HCP Hatchery Committee regarding the PUD M&E Plan*. Hillman said this item was available for review and discussion in December and no major issues were identified. Further, he received no requests from the HCP-HC or PRCC HSC representatives asking for additional information from the geneticists. Mike Tonseth suggested including this background information in the M&E Plan for PUD Hatchery Programs (update to the 2017 Plan). He said the responses from geneticists confirmed the committees are correct in their assumptions about monitoring. Hillman suggested also appending the document from the geneticists to the M&E Plan.

Todd Pearsons said there was one question about whether linkage disequilibrium was calculated for both hatchery and natural fish and asked if this has been resolved since the last conference call with geneticists. Greg Mackey confirmed the work has been done and included in the previous genetic reports. Pearsons said one reason feedback is needed now was to make sure genetic analysis was included in the M&E Plan to allow the PUDs to initiate contracting for genetics analysis and reporting.

Hillman asked the HCP-HC and PRCC HSC whether to include analysis for linkage disequilibrium (item No. 1 in the response from geneticists) in the current M&E Plan, which would allow the PUDs to contract for the work accordingly. Representatives present from the Wells, Rocky Reach, and Rock Island HCP HCs and PRCC HSC (Douglas PUD, Chelan PUD, Grant PUD, USFWS, YN, WDFW, and CCT) approved adding linkage disequilibrium analysis to the M&E Plan. A NMFS representative was not present (and unable to respond to a delayed vote for longer than 5 business days); therefore, NMFS abstained from voting. (Note: Brett Farman (NMFS) approved via email on February 13, 2019.)

Catherine Willard volunteered to update the M&E Plan by the March meeting.

B. Broodstock Collection Protocols Review (Todd Pearsons)

Mike Tonseth stated the level of likely adult management needed this year will likely be minimal due to low predicted returns for spring and fall Chinook salmon. He predicts meeting broodstock targets will be difficult. Todd Pearsons asked whether the HCP-HC and PRCC HSC can move forward with reviewing the broodstock collection protocols without run projections, because they have been a cause of delay in previous years. Tonseth answered that WFDW is on time for drafting the 2019 Broodstock Collection Protocols with run projections. Because early forecasts were showing such low numbers, WDFW is prioritizing incorporating realistic numbers into the protocols before releasing them for review. Tonseth said he will share the draft 2019 Broodstock Collection Protocols before February 10, 2019.

Pearsons said there is a need to resolve the discussion around the use of jacks in the broodstock. He said the existing protocols are very prescriptive. He asked if the protocols can be revised so they are more like guidelines rather than prescriptions—define the ideal but provide ways to deviate and find alternative choices. Tonseth said he has revised the draft for some programs to have less prescriptive protocols and allow for defaulting to backup options if in-season run forecasting changes.

Tracy Hillman reviewed issues that were raised during discussions of the 2018 Broodstock Collection Protocols (summarized in the document, *Emerging Discussions from draft 2018 Broodstock Collection Protocols*) to determine which ones are still outstanding.

1. Yakama Nation Summer Chinook Egg Requests at Wells Hatchery

This item was discussed throughout 2018 and is no longer outstanding.

2. Use of Age-3 Males in Broodstock

Greg Mackey is continuing to work on this item as discussed during review of the action items.

3. Bacterial Kidney Disease Risk Assessment

Hillman said this outstanding issue is whether WADDL's testing and reporting methods for BKD risk assessment are consistent with PUD program management, monitoring and reporting requirements. Tonseth said WDFW performed enzyme-linked immunosorbent assay (ELISA) testing in 2018 because WADDL's laboratory was not set up to complete the testing. Mackey said Betsy Bamberger coordinated with WADDL regarding how to report ELISA results in a way that managers are able to use the results to make decisions consistent with the past (i.e., using optical density [OD] values), but WADDL was reticent to produce an OD number that does not meet certified laboratory standards. Tonseth said from a resource management perspective this is still useful. Mackey said WADDL's approach is that if a fish has both a positive ELISA and quantitative polymerase chain reaction (qPCR) result, it is confirmed positive for BKD; however, the fish may be subclinical for pathology. Tonseth noted that a 2006 SOA specifies that OD values will be used to determine BKD risk assessment—this SOA would need to be updated. Tonseth said broodstock collection protocols are developed based on OD values for when to cull and when not to cull, so to be consistent with 2019 protocols, WADDL would need to provide a methodology that is relatable to the OD methodology.

Kirk Truscott asked whether a broodstock overage is always collected to allow for culling. Tonseth said yes, and if programs use WADDL for BKD risk assessment, there needs to be a method that allows managers to cull within the overage collected.

Mackey noted the WADDL approach is a more rigorous test and is less prone to false positives.

Mackey said he will work with Bamberger to compare the different testing and reporting methods between WDFW laboratories and WADDL and determine a management approach comparable to past years.

Hillman said this is a topic for future HCP-HC and PRCC-HSC meetings. Secondarily, the committees will need to determine whether a new SOA is needed with a new protocol for BKD culling.

4. *Differentiating Natural-Origin Okanogan River Spring Chinook Salmon During Methow Fish Hatchery Broodstock Collection at Wells Dam*

Hillman said this outstanding issue is how to identify Okanogan River natural-origin spring Chinook salmon from other natural-origin stocks during broodstock collection at Wells Dam for the Methow Fish Hatchery. This item is not relevant in 2019 but will be in the near future. Truscott and Tonseth determined the first 4-year-old returning fish from the Okanogan program will need to be differentiated at Wells Dam beginning in 2021.

Representatives present discussed possible methods for differentiating the stocks. Tom Kahler asked whether elemental scale analysis is a possible method. Truscott answered that it is possible to observe a signature from tributaries in different basins. The difficulty would be catching, holding, and analyzing fish in time. Pearsons said this was done with fish collected at Tumwater and results were mixed. Laser ablation was done on scales, fins, and otoliths. Life-history variation made it difficult as fish moved around between waters. Tonseth asked whether there is a way to set up methods in 2020 to analyze 3-year-old returners. Mackey suggested collecting yearling juveniles in September to test the methods. Truscott said that would likely not work because managers would need to collect scales from wild yearling smolts known to originate from the Okanogan. However, he said it may be worthwhile to collect scales in the future from PIT-tagging efforts and snorkel surveys. Tonseth agreed that it may be worthwhile to start analysis now to determine a baseline, but he does not know of an easy way to differentiate adults. Hillman said elemental signature analyses work but are costly. Truscott agreed and volunteered to discuss internally the feasibility of using elemental signature analysis for differentiating adults.

5. *Priest Rapids Hatchery Fall Chinook Salmon Integration – How to Achieve It Without Fish from Alternative Collection Sites/Methodology*

Hillman said this issue is about whether fall Chinook salmon adults collected at various collection sites can be integrated into the broodstock.

Tonseth said hook and line provided many more natural-origin fish than sampling at the OLAFT in 2018. Pearsons said the time between when the fishery was closed and when hook-and-line collection started created a situation where fish were readily caught this year and survived transport well. Tonseth said based on the current run forecast, this could be repeated in 2019. Pearsons said staff working on fish transportation were overwhelmed on the first day and methods for handling will be improved in the future. Tonseth said it may be good practice to allow 1 week between fishery closure and broodstock collection. Pearsons agreed but said collecting too late begins to overlap with fish spawning, which is not desirable for broodstock collection.

6. *Conservation Program Size*

Hillman said this topic is about adjusting conservation program sizes for upper Columbia spring Chinook salmon to make sure programs are set at biologically defensible levels.

Hillman asked whether the draft 2019 Broodstock Collection Protocols will include any adjustments to sizes of conservation programs. Tonseth said the discussion hasn't been had with the Yakama Nation yet given interim timing on analyses using previous methods and updating those data. There are new data to incorporate. Tonseth said he would also like to see life-cycle modeling results. If there is a size adjustment in the 2019 protocols, it will be an interim proposal based on the original methodology. He said it may not make a difference this year as they will be limited to one third of the run for broodstock collection and will likely need to use safety-net fish for the Chiwawa program. Pearsons asked for clarification. Keely Murdoch said that the end goal is to determine how many natural-origin fish will be used for broodstock. Technically the conservation program would be the same size but would be backfilled by safety-net fish, as needed. The safety-net program would increase if the conservation program decreases. If there are not enough natural origin fish to meet the requisite component, then the shortfall will be backfilled by hatchery progeny. Tonseth said if they were to collect the target number of natural-origin fish for the Nason program in 2019, that may require collecting the entire run and the program would be in the negative for natural-origin fish returning back to Nason Creek. He said we need to avoid "mining" the Chiwawa program to meet these needs. Pearsons asked, for instance, if the run projection is 75, the program would take one third (25 fish) and back-fill with safety-net fish? Tonseth answered yes. Pearsons said we may not need to know conservation program adjusted numbers for 2019—but it seems to take a long time to get updated program size so we should continue to work on it regularly (based on life-cycle modeling and pre-spawn mortality).

Pearsons asked whether the spawner-recruitment curves and assumptions could be updated in the meantime with more recent information. Hillman answered the analyses will be updated for the 10-Year Program Review report. Pearsons suggested that escapement calculations could be based on adult-to-juvenile escapement, because it seems like the adult-to-juvenile data are cleaner, with stronger correlations (r value). Hillman said this was true for some tributaries (such as the Chiwawa River), but not for others (such as the White River and Nason Creek).

Tonseth said these analyses will make no difference for how fish are allocated in 2019 due to low projected numbers but agrees these are important for future years and proposed updating targets and collection curves with interim values while data are being finalized. Murdoch said updating pre-spawn mortality data is the highest priority, specifically, including details on sex-specific and hatchery versus wild variation in pre-spawn mortality. She said WDFW is working on pre-spawn mortality data and suggested that they could provide a pre-spawn mortality average for updating the calculations in the meantime while data are being finalized. Tonseth said Tumwater Dam is the location at which those fish can be managed, so having accurate estimates of pre-spawn mortality upstream from Tumwater Dam is important to management. Kahler said he believes migration through Tumwater Canyon is an energetic challenge and pre-spawn mortality would largely manifest itself upstream from the dam. Tonseth said there is a significant difference in pre-spawn mortality between natural-origin and hatchery-origin fish that could be due to differences in fat reserves. Murdoch said this could also be related to where different fish hold and the habitat quality in those holding areas; some holding areas are energetically expensive, such as in the lower Chiwawa River.

Murdoch shared the spreadsheet, "2018 Sliding Scale and Safety Net Update with composite analysis and current sliding scale," which Sarah Montgomery distributed to the committees on January 3, 2019 (Attachment B). She said the spreadsheet included updated escapement numbers, updated smolt-to-adult return rates, and updated broodstock needs. Pearsons asked what other items should be updated, even if data are provisional. Tonseth answered that spawner escapement (for the future years) should be updated. Murdoch said the analysis is mainly missing updates to escapement goals, pre-spawn mortality, and needs an updated adult-to-adult spawner-recruitment goal. A new curve could be used for the next spawner escapement estimate. Hillman said he will be updating spawner-recruitment curves for the 10-Year Program Review report. Tonseth said he will ask Andrew Murdoch whether interim information can be used to update curves now, with footnotes indicating the curves are provisional and to be updated as pre-spawn mortality data are updated.

Pearsons asked what the next program is for evaluating changes to program size. Tonseth and Murdoch said the Wenatchee program should be analyzed and updated as much as possible before the Methow program, which does not yet have a management plan or technical document dictating the size of conservation programs in the basin. Tonseth said this has long been a recognized need for the Methow program and asked whether there is a need for a full-blown management plan as in the Wenatchee or something smaller. Pearsons asked if a rough schedule could be developed for including updated conservation size numbers for the Methow program in the 2020 broodstock collection protocols with the main motivation to avoid using more natural-origin fish than necessary. Tonseth said there is no previous analysis in the Methow to fall back on, so this will be a substantial amount of work, but can certainly be a goal for the committees. Kahler said that Douglas had analyzed this during the consultation for the Methow spring Chinook programs and had data and analysis to provide in the interim.

A discussion was had about adding a safety-net program to the Methow Hatchery programs. Murdoch asked whether a new population proportionate natural influence (PNI) model is needed for the Methow basin. Tonseth said there is no need for an additional safety-net program in the PNI model. Tonseth and Matt Cooper said the approach is to treat the Methow basin as an aggregate.

Pearsons said he is interested in completing these analyses and updates so it can be incorporated into the 2020 broodstock collection protocols knowing not all analyses or discussions will be done. Tonseth agreed but said it may not be reasonable due to uncertainties about feasibility. Pearsons asked to add the topic of evaluating conservation program sizes to the meeting agenda every few months to continue progress. Larissa Rohrbach said she will maintain this topic as a periodic agenda item.

Hillman said WDFW previously discussed streamlining the broodstock protocols and asked Tonseth how this effort is going. Tonseth said the protocols are shorter than previous years and he continues to find areas to streamline.

C. Re-Evaluating Conservation Program Size

See above discussion, Item II.B.6.

D. Brood Year 2020 Steelhead Sampling at the Off-Ladder Adult Fish Trap

Mike Tonseth informed the committees that WDFW PIT-tagging efforts at the Priest Rapids Dam OLAFT will switch from steelhead to spring Chinook salmon. This work is funded by the Bonneville Power Administration (BPA), and WDFW is proposing to use those funds to develop spring Chinook salmon mark-recapture escapement models. Thus, the PUDs may need to take over some portion or all of steelhead sampling at the OLAFT (in 2019) and/or funding future PIT-tag arrays operation and maintenance (O&M) that will lose funding from BPA. He said key questions to support a PIT-tag-based escapement model for steelhead have been answered and WDFW plans to redirect funds to the study of spring Chinook salmon. WDFW cannot use BPA funds to fund both steelhead and spring Chinook salmon investigations. He said WDFW needs to know whether there will be a PUD funding back-fill for PIT-tag-based steelhead work by early March. If there is no plan to fund steelhead sampling at the OLAFT, PIT-tag arrays currently funded by BPA for steelhead will be turned off for steelhead returns and switched on again for spring Chinook salmon returns. This affects the 2020 brood because sampling for brood at the OLAFT occurs in 2019. He said sites may be switched off in July 2019.

Tom Kahler asked for clarity on discretionary funding and the impetus for moving investigations to spring Chinook salmon rather than continuing work with steelhead. Kahler asked what the program will get from switching to spring Chinook salmon. Tonseth answered that this would allow for estimating spawning and pre-spawn mortality with a PIT-tag-based model rather than relying on spawner surveys. Keely Murdoch said there is a knowledge gap between spring Chinook salmon returning and spawning. In the Wenatchee Basin, data collected at Tumwater Dam and the reproductive success study provide some information, but there is a data gap for the rest of the upper Columbia Basin. Kahler said some of that information is available from sampling at Wells Dam. Tonseth said sampling at the OLAFT addresses the entire evolutionary significant unit, whereas sampling at Tumwater or Wells dams addresses local populations. Specifically, information is lacking on pre-spawn mortality in the Entiat River and lower Wenatchee River to estimate mainstem Columbia impacts to tributary populations. Kahler said it seems preliminary to use a PIT-tag-based model for spring Chinook salmon until results are finalized for steelhead.

Catherine Willard asked if WDFW is seeking PUD funding for the 2019 steelhead PIT-tagging at the OLAFT if the PUDs choose to use PIT-tag-based escapement calculations. Tonseth said he is making the PUDs aware that WDFW's plan is to move the funding to spring Chinook salmon because WDFW has determined their work on steelhead is complete. The redd-count-based model and PIT-tag-based model are currently available. He said the intent of this discussion to inform the HCP-HC and PRCC-HSC that PIT-tag-based escapement estimates for steelhead may not be available for 2020 without funding from the PUDs. The PUDs could fund PIT-tagging at the OLAFT or array O&M; although, the cost of array O&M is less predictable.

Kirk Truscott asked whether the lack of funding will affect PIT-tag arrays in the Okanogan and how eliminating arrays would affect spawner escapement estimates. Tonseth said certain arrays would stay on; the lowest mainstem arrays would stay functional for adult management and most others would be turned off. Truscott said most in the Okanogan would remain functional as they are funded by other entities, but there is a concern that money spent maintaining arrays in the Okanogan may not be well-spent if arrays in the Methow are being turned off and spawning escapement cannot be estimated because the PIT-tag-based model relies on escapement data from other tributaries. Tonseth said this should not be a concern because the lowest array will still be operating.

Todd Pearsons asked whether the BPA funding is Accord funding that goes to the State. Tonseth answered this is BPA Accord money that goes to WDFW to fund BPA's mitigation obligations; the State has some flexibility on where to use the funding. Willard asked if BPA needs to approve the switch of funding from sampling steelhead to Chinook. Tonseth stated WDFW informs BPA how the funding is being used. Tracy Hillman provided some history on how monitoring activities were identified for BPA funding. He said several years ago the region identified steelhead escapements as a data gap. It appears the data gap has been addressed with the development of the mark-recapture model and WDFW is now proposing to use BPA funding to address other data gaps. Hillman said it is up to the HCP-HC and PRCC HSC to determine if they will use the model, which requires PIT tagging and PIT-array maintenance, or use a different approach to estimate steelhead escapement. He said for spring Chinook salmon, carcass surveys will still be needed even if an escapement model is developed. The distribution of natural-origin and hatchery-origin fish is not well addressed with mark-recapture models.

Greg Mackey said the factors in this decision for Douglas PUD are sampling fish at Wells Dam versus OLAFT. The program could stop stock assessment at Wells Dam and could cut back collection in the fall at Wells Dam, but Douglas PUD needs to know how many arrays need O&M and how many are critical for decision making. Programs need to do a cost-benefit analysis to determine the most effective choice. Mackey asked whether other entities like the USFWS would contribute if they are producing steelhead, or are all entities producing spring Chinook salmon going to participate. It would be difficult to support PIT-tagging or array O&M if only one PUD supports it. Kahler said there is added scrutiny because PUDs are not allowed to fund activities without remuneration. Tonseth said it may make sense for the PUDs to fund arrays that are required for meeting obligations rather than PIT-tagging.

Truscott asked whether WDFW would begin PIT-tagging spring Chinook salmon at the OLAFT in 2020 and whether a permit is needed. Tonseth said that technically, their permits already allow sampling at Priest Rapids Dam. Truscott said he recalled issues with fish movement at the OLAFT. Pearsons said spring Chinook were delayed due use of the OLAFT during the year of the Wanapum Dam fracture. Truscott agreed that presents one problem and asked whether another problem could be a funding shortfall for both tagging and array O&M—if there is no PIT-tagging, there would be no reason to maintain arrays. Tonseth confirmed WDFW will fund either PIT-tagging at OLAFT or PIT array O&M, but not both.

Willard requested that Andrew Murdoch provide the PUDs with a list of arrays at risk of being shut down, the cost of maintaining those arrays, and the cost of tagging at Priest Rapids Dam.

Kahler asked what protocol would be followed for sampling spring Chinook salmon at the OLAFT. Tonseth answered the work would be the same as for steelhead in terms of staff time and tagging approximately 15% of the run. Kahler asked whether there is a concern about exacerbating pre-spawn mortality due to handling. Kahler said that adding another handling event to spring Chinook salmon will contribute to pre-spawn mortality, but at an unknown rate. Tonseth agreed there will be some double handling of fish, for instance at Priest Rapids and Tumwater dams, but the total number of fish handled will be less. Kahler asked whether they will all be trapped. Tonseth answered no. At Tumwater Dam (and Wells Dam), trapping would only be for adult management and broodstock collection because sampling at Priest Rapids Dam will have already collected data on age, gender, and other metrics, so fewer fish would be handled at upstream sites. Kahler said that reasoning may not apply to Wells Dam, where many wild fish need to be handled. Tonseth said a sort-by-code system could be used at upstream sites to avoid excessive handling if fish are tagged and sampled at Priest Rapids Dam.

Kahler said history indicates that teaming with BPA leads to establishing programs that then require PUD funding in the future. Truscott said the other way to look at it is that BPA funds the development of models, which then can be used by the PUDs for monitoring. Kahler said this is true for steelhead, but he does not see the utility for spring Chinook salmon because of the need to continue spawning-ground surveys to obtain carcass data. Murdoch said perhaps the PIT-tag data will provide more information or maybe it will be determined that carcass surveys provide more useful data for spring Chinook salmon. Programs should consider the best data sources on a case-by-case basis. Pearsons said that the same market forces (power prices) that are currently influencing BPA decisions and the same market conditions can also affect the PUDs funding decisions.

E. Streamlining HCP-HCs and PRCC HSC Meetings

Tracy Hillman summarized that the goal of facilitating HCP-HC and PRCC HSC meetings is to increase efficiency, but there is also a need to maintain separation between the committees. The following materials or approaches could be merged:

- Agendas and Minutes: Hillman suggested developing one set that covers everything and is sent to all members of all committees. Materials would be distributed in emails (rather than having to search a SharePoint site). The Grant PUD SharePoint and Douglas PUD Extranet sites would be treated as repositories for materials, but all materials will go out over email.

- Distribution lists: Sarah Montgomery said the distribution lists need to be approved by the HCP Coordinating Committees for distributing Wells, Rocky Reach, and Rock Island HCP materials to non-committee members. Douglas PUD and Chelan PUD need to review their rules about distribution. Representatives present agreed that draft minutes and draft materials should only go to representatives and alternates due to confidentiality requirements. Anything final should go to the larger distribution groups. Larissa Rohrbach said she will develop proposed distribution lists and send them out to representatives and alternates for their review. Once the HCP-HC approve the lists, they will be provided to the HCP Coordinating Committees for approval.
- Protocols: Hillman noted his roles for the HCP-HC is Chairman and for the PRCC HSC is Facilitator, which entail different roles in decision-making processes between the HCP-HC and PRCC and HSC. Rohrbach will update protocols to reflect merging meeting forums and make any updates based on the realistic application of the protocols. Rohrbach will send updated protocols to representatives and alternates for approval. Hillman said the protocols need updated language on conflicts of interest and will send updated language to representatives and alternates for approval.
- Agenda order: Hillman asked whether the order that the committees present their items on the agenda should rotate or be fixed. All agree that Joint HCP-HC items should come first, then committees with shortest agenda items (i.e., those that can be addressed quickly) should go first following joint items. Todd Pearsons asked whether predicted times could be added to the agenda. Hillman said there has been pushback against this idea within the HCP-HC because they want to make sure agenda items are fully vetted without a time limit. Mike Tonseth said adding times lets invited speakers know when they should arrive or call into the meeting. Greg Mackey said time limits are good for items that may not be resolved in the current meeting. All agreed to include estimated times for each agenda item (representatives will include a time estimate when they propose an agenda item).
- Naming conventions: the committee name will be used to indicate discussion topics (i.e., Wells HC, Rocky Reach HC, Rock Island HC, and PRCC HSC) in both the agenda and meeting notes. In merged materials, the group will be named "HCP-HC and PRCC HSC" or shortened to "HC/HSC."

All HCP-HC and PRCC HSC representatives present (Chelan PUD, Douglas PUD, Grant PUD, USFWS, WDFW, YN, CCT) voted to approve merging attendance, meeting agendas, meeting minutes, documentation, and distribution of materials in emails for HCP-HC and PRCC HSC business. A NMFS representative was not present and unable to respond to a delayed vote for longer than 5 business days; therefore, NMFS abstained from voting. (Brett Farman [NMFS] approved via email on February 13, 2019).

III.Wells Hatchery Committee

A. Douglas PUD 2019 Implementation Plan (Greg Mackey)

Keely Murdoch said the status quo in the Douglas PUD 2019 M&E Implementation Plan may not work for steelhead if certain aspects of steelhead PIT tagging and data analyses are not funded by BPA. Therefore, she requested revisions to the plan allowing for flexibility for planning around this uncertainty, as representatives did for the Chelan PUD 2019 Implementation Plan. Greg Mackey said the proposed revisions seemed vague, so he has not decided whether to send that version to the HCP-HC for approval. Murdoch said she attempted to use the same language as was approved for the Rocky Reach and Rock Island Plan that draws attention to the potential changes in activities in 2019 to support broodstock selection. Mackey said if a version with this proposed revision is approved, he foresees a need for a one-page amendment in the future once it is clear what methods will be used to enumerate steelhead. Murdoch said as phrased this does not commit Douglas PUD to one course of action or another. Mackey said the edits to the Douglas PUD plan have not been discussed yet and that today's discussion on funding PIT-tagging activities and arrays created the need for further internal discussion before finalizing the 2019 M&E Implementation Plan language. Mackey said he will distribute a revised version of the plan to the committees for approval once Douglas PUD discusses this internally.

IV. Rocky Reach and Rock Island Hatchery Committees

A. 2019 Spring Chinook Salmon and Coho Salmon Final Acclimation at Chewuch Pond (Catherine Willard)

Catherine Willard provided an update and reminder that 2019 is the first year coho salmon and spring Chinook salmon will be co-acclimated together in the Chewuch Pond. She said 80,000 coho salmon will be co-mingled with spring Chinook salmon. Chelan PUD is operating the pond.

B. Tumwater Dam Fishway Maintenance Update (Catherine Willard)

Catherine Willard provided an update on fishway maintenance at Tumwater Dam involving reinforcing the walls around the fishway. She said completion of the project has been delayed and the project will not be completed until mid- to late-March. The fishway will remain open through that time. Trapping will still occur at night around construction activities. Mike Tonseth said WDFW will be doing minimal adult management at Tumwater Dam this year and may not need to trap fish.

V. PRCC HSC

A. Committee Updates and Meeting Summary Review (Todd Pearsons)

Todd Pearsons asked the PRCC HSC representatives whether it is still useful to have routine updates on the activities of other committees such as the Fall Chinook Work Group, PRCC, or U.S. v. Oregon. Pearsons recommended eliminating these routine updates due to lack of interest and time constraints, but if there are important issues from other committee meetings, these will be brought onto the agenda. All representatives present agreed.

Pearsons said the November conference call meeting summary is going to be approved via email votes provided to Andy Chinn (Ross Strategic). Pearsons requests that all members make their votes before the end of January so Ross Strategic can finalize the last meeting summary of 2018.

VI. Administration

A. Next Meetings

Hillman asked the HCP-HC and PRCC HSC whether they want to schedule an additional conference call in March to potentially discuss broodstock collection protocols. All agreed. Sarah Montgomery noted the best date based on responses to the poll is March 11. All agreed to a potential conference call on March 11, 2019, at 2:30 p.m.

The next HCP-HC and PRCC HSC meetings are on February 20, 2019 (Grant PUD), potential conference call on March 11, 2019, and March 20, 2019 (Grant PUD).

Summary

1. Sliding Scale

a. Suggest initially implementing sliding scale A (or similar). Sliding Scale A is based upon the range in NOR runs sizes observed between 1999 and 2008. PNI of 0.67 will likely be achieved in the near term. Sliding scales based on percentiles will need to be revisited and adjusted as increased NOR run sizes return. Suggest revisiting sliding scale on 5-year intervals.

b. Sliding Scale B is based on the range of run sizes that might be observed, limited by the escapement goal. If sliding scale B is used in the near term, PNI goals will likely not be met. However a sliding scale based upon the range of run sizes may be appropriate as we begin to see larger run sizes. Alternatively a sliding scale based upon the range of run sizes observed may need to be adjusted as run sizes increase.

2. Conservation / Safety Net program options

Options were run modeling results (PNI and escapement upstream of TWD) using varying conservation / Safety Net program sizes

1 **Conservation / Safety Net (100% and 0%)** resulted in large numbers of excess HOR to be surplused, severe restrictions on spawning escapement, and the lowest PNI of all options modeled.

2 **Conservation / Safety Net (67% and 33%)** resulted in a slightly higher total escapement upstream of TWD and slightly improved PNI, however escapement was still largely restricted below goals and large surpluses of hatchery origin fish still occur on a regular basis

3 **Conservation/ Safety Net (50% and 50%; For the Chiwawa Program this would be a 150K conservation program)** resulted in a higher total escapement, meeting escapement goals in 6 of 10 years, and PNI goals are met. Excess HOR are reduced. However in lowest return years HORs from the conservation program may be insufficient to meet escapement goals associated with the PNI and broodstock goals.

4 **Conservation / Safety Net (33% and 67%)** resulted in the highest total escapement with the least amount of excess HORs, however given the small size of the conservation program, HOR fish may not be available in low to moderately low years to meet the escapement goals associated with the sliding scale of PNI. So this option may not actually result in higher escapements.

A. Based on Percentiles or NOR returns from 1999-2008

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: March 28, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the February 20, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCP) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, February 20, 2019, from 9:00 a.m. to 3:30 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Tracy Hillman will review aspects of the Independent Scientific Advisory Board's Review of Spring Chinook Salmon in the Upper Columbia River under HCP-HCs' purview (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook at the Methow Hatchery; Item I-A). *(Note: Larissa Rohrbach distributed an email from Mackey including a paper and presentation by Hankin et al.[1,2] to the HCP-HCs and PRCC HSC representatives on February 22, 2019. This item is ongoing.)*
- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) regarding presenting pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HCs meeting (Item I-A). *(Note: this item is ongoing)*.
- Catherine Willard will update the genetics section of the Monitoring and Evaluation Plan for PUD Hatchery Programs (Update to the 2017 Plan) based on the genetics panel

[1] Hankin, D. G., J. Fitzgibbons, and Y. Chen, 2009. "Unnatural Random Mating Policies Select for Younger Age at Maturity in Hatchery Chinook Salmon (*Oncorhynchus Tshawytscha*) Populations." *Canadian Journal of Fisheries and Aquatic Sciences* 66(9):1505-1521.
[2] Hankin, D. G., J. Fitzgibbons, and Y. Chen, 2011. *Unnatural Random Mating Selects for Younger Age at Maturity in Hatchery Chinook Salmon Stocks*. Oral presentation.

recommendations and will append the recommendations from the panel to the plan (Item I-A). *(Note: this item is ongoing.)*

- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*
- Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A). *(Note: this item is ongoing.)*
- The following updates will be made to the draft 2019 Broodstock Collection Protocols pertaining to Joint HCP-HCs and PRCC HSC items (Item II-A):
  - Mike Tonseth will add Appendix C to the draft 2019 Broodstock Collection Protocols describing return-year adult management plans.
  - Greg Mackey will revise Douglas PUD's broodstock collection protocol for Methow coho salmon captured at Wells Dam.
  - Kirk Truscott will comment in the draft broodstock collection protocol regarding the number of steelhead collected in the fall that have intact adipose fins and no coded wire tag (CWT).
  - Keely Murdoch will provide the number of summer Chinook salmon eggs required from Wells Hatchery for the Yakima Basin program.
  - Tonseth will revise language about the allocation and marking of spring Chinook salmon in the Nason Creek conservation and safety-net programs.
  - Tonseth will distribute a revised version of the Broodstock Collection Protocols by March 6, 2019, to be discussed on the March 11, 2019 conference call.

  (Note: Rohrbach distributed an email from Tonseth including revised draft 2019 Broodstock Collection Protocols to the HCP-HC and PRCC HSC on March 8, 2019).
- Mike Tonseth will distribute the costs of tagging steelhead at the Priest Rapids Dam Off-Ladder Adult Fish Trap (OLAFT) and the upper Columbia River passive integrated transponder (PIT)-array operation and maintenance (O&M) budgets to the PUDs and inform the Chair when this has been distributed (Item III-A). (*Note: Tonseth emailed Tracy Hillman on February 25, 2019, to inform him that this item is complete.*)
- Mike Tonseth will invite Andrew Murdoch to the next HCP-HCs and PRCC HSC meetings on March 20, 2019, to answer questions about PIT-tagging spring Chinook salmon at the OLAFT (Item III-A). *(Note: Tonseth emailed Tracy Hillman on February 25, 2019, to inform him that Murdoch will attend the March 20, 2019 meeting. This item is complete.)*
- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating the proportionate natural influence (PNI) for the Nason spring Chinook and Chiwawa spring Chinook programs (Item II-A).

- Brett Farman will inform the HCP-HCs of the publication date for public review of the Methow River Steelhead Environmental Assessment (EA) (Item II-C).
- Brett Farman will inform the HCP-HCs of the publication date for public review of the Section 10 permit for the unlisted Chinook salmon bundle (Item II-C). *(Note: Farman emailed Larissa Rohrbach on March 6, 2019 to inform the Committees that the UCR unlisted Chinook NEPA and HGMP bundle will be published within the week.)*

Wells HCP Hatchery Committee

- Greg Mackey will provide a revised version of Douglas PUD's draft 2019 Monitoring and Evaluation (M&E) Implementation Plan for HCP-HCs approval by email (Item III-A).

PRCC Hatchery Subcommittee

- The following updates will be made to the draft 2019 Broodstock Collection Protocols pertaining to PRCC HSC items (Item V-B):
  - Mike Tonseth will revise the Broodstock Collection Protocols for the natural-origin (NOR) Methow (Carlton) summer Chinook salmon program to identify a seasonal target number of adult fish to be collected rather than weekly collection goals due to low numbers expected in 2019.
  - Tonseth will review the assumptions and target number of proposed NOR Methow (Carlton) summer Chinook salmon to determine if this number could be increased similar to 2018 targets.
  - Todd Pearsons will organize a conference call with Tonseth and Paul Hoffarth (WDFW) to develop a plan to determine the number of fall Chinook salmon broodstock to be collected during the 2019 Angler Broodstock Collection (ABC) fishery and the OLAFT.

  (Note: Rohrbach distributed an email from Tonseth including revised draft 2019 Broodstock Collection Protocols to the HCP-HC and PRCC HSC on March 8, 2019).

Decision Summary

- There were no decisions approved during today's meeting.

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- Larissa Rohrbach sent an email to the Rocky Reach and Rock Island HCs on February 11, 2019, notifying them that the 2019 Rock Island and Rocky Reach HCP Action Plan is available for a 30-day review with edits due to Catherine Willard by March 13, 2019 (Item IV-A).
- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on February 12, 2019, notifying them that the draft 2019 Broodstock Collection Protocols are available for review with comments and edits due to Mike Tonseth by March 1, 2019 (Item II-A and V-B).
- Larissa Rohrbach sent an email to the PRCC HSC on February 21, 2019, notifying them that the draft Priest Rapids Hatchery M&E Implementation Plan is available for 30-day review with comments and edits due to Todd Pearsons by March 25, 2019 (Item V-C).
- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on February 7, 2019, notifying them that the updated meeting protocols, distribution lists, and draft Conflict of Interest Statement of Agreement (SOA) are available for review with comments and edits due to Rohrbach by March 15, 2019 (Item II-B).

Finalized Documents

- No items have been recently finalized.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and approve the January 16, 2019 Meeting Minutes (Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and asked for any additions or changes to the agenda. Three items were added to the agenda:

- Greg Mackey added an announcement of a job opening at Wells Hatchery to the Wells HC agenda items
- Catherine Willard added an update on the Tumwater fishway to the Rocky Reach and Rock Island HC agenda items
- Todd Pearsons added the 2019 Draft Priest Rapids Hatchery M&E Implementation Plan to the PRCC HSC agenda items

The HCP-HCs and PRCC HSC representatives approved the revised agenda.

The HCP-HCs and PRCC HSC representatives reviewed the revised draft January 16, 2019 meeting minutes. Larissa Rohrbach said there are some outstanding comments and revisions, which the representatives reviewed and addressed. The HCP-HCs and PRCC HSC representatives approved the draft January 16, 2019 meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on January 16, 2019, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on January 16, 2018)*:

Joint HCP-HCs and PRCC HSC topics

- *Tracy Hillman will review aspects of the Independent Scientific Advisory Board's* Review of Spring Chinook Salmon in the Upper Columbia River *under HCP-HCs' purview (Item I-A).* Hillman said this item is ongoing. Hillman said he has the statistical tools for analyzing total spawners in a BACI analysis, and is now developing the tool for analyzing productivity by return year. Next, he plans to figure out when the before and after treatment time periods should be: that is, when hatchery fish would first start to affect the productivity of natural-origin fish.
- *Greg Mackey will continue researching whether to include age-3 males in broodstock and discuss it with Craig Busack (National Marine Fisheries Service [NMFS]; Item I-A).*
  Mackey said this item is ongoing. Mackey said he identified a paper by Hankin et al. for distribution about modeling age structure of a hatchery population. Hankin et al. found that a simple protocol of structuring broodstock management to mate females with larger males can shift the population to an older age structure and prevent the shift to a younger age structure. A 2x2 factorial approach is used now in the Methow spring Chinook salmon program. In addition, due to genotyping all potential brood for stock identification, the capacity exists to identify full-sibs and half-sibs to avoid those crosses. Todd Pearsons said this approach was used in the White River. Catherine Willard said this approach was used for Snake River Sockeye at Redfish Lake, Idaho. Bill Gale asked if there is a minimum number needed for this approach to work. Tom Kahler agreed this was an important question and noted the Methow program is small. Gale said this may not be possible for conservation programs that are small.
- *Keely Murdoch will attempt to provide coho salmon broodstock collection protocols to Mike Tonseth by early February for inclusion in the draft 2019 Broodstock Collection Protocols (Item I-A).*
  Murdoch said this item is complete. Murdoch said the protocol is ready and will be distributed following the meeting.
- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) regarding presenting pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HCs meeting (Item I-A).*

Tonseth said this item is ongoing.

- *Keely Murdoch will research past co-mingling ratios of coho salmon to spring Chinook salmon at Winthrop National Fish Hatchery or other locations (Item I-A).*
  Murdoch said this item is complete. Murdoch identified years in which co-mingling occurred. She said that the ratio centered around 50% (49-53%) coho salmon over those years at the Spring Creek acclimation site but that at the Twisp acclimation site it would be mostly coho salmon. Greg Mackey said the ratio would be approximately one-third Chinook salmon and two-thirds coho salmon.
- *Larissa Rohrbach will obtain approval or abstention from NMFS to approve the December 2018 meeting minutes (Item I-A).*
  Rohrbach said this item is complete. NMFS did not respond to a request for a vote within 5 business days and therefore abstained. Brett Farman [NMFS] approved via email on February 13, 2019.
- *Larissa Rohrbach will schedule a tentative conference call on March 11, 2019, at 2:30 pm for the HCP-HCs and PRCC HSC to discuss the draft 2019 Broodstock Collection Protocols (Item I-A).*
  Rohrbach said this item is complete. Rohrbach sent a calendar placeholder via email on January 28, 2019.
- *Catherine Willard will update the genetics section of the* Monitoring and Evaluation Plan for PUD Hatchery Programs (2017 Update) *based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item II-A).*
  Willard said this item is ongoing.
- *Mike Tonseth will share draft 2019 Broodstock Collection Protocols with the HCP-HCs and PRCC HSC by February 11 (Item II-B).*
  Rohrbach said this item is complete. Larissa Rohrbach distributed the 2019 Broodstock Collection Protocols in an email on February 12, 2019.
- *Greg Mackey will confirm with Betsy Bamberger (Douglas PUD) whether Douglas PUD will use the Washington Animal Disease Diagnostic Laboratory (WADDL) for in-season bacterial kidney disease (BKD) testing during 2019 broodstock collection and confirm that WADDL methods will provide ELISA [enzyme-linked immunosorbent assay] optical density test results (Item II-B).*
  Greg Mackey said this item is ongoing. Greg Mackey said Douglas PUD still plans to use WADDL, but it is unclear at this time if WADDL plans to report optical density (OD) values. If Douglas PUD cannot get the ODs through WADDL, they will contract with the State of Washington. Mike Tonseth asked if there is similarity in how the ODs are interpreted by both laboratories to determine if culling is needed in-season. Mackey said Bamberger is in the process of determining this. This topic will be added to an upcoming meeting agenda with Bamberger.

- *Kirk Truscott will discuss with Colville Confederated Tribe (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item II-B).*
  Truscott said this item is ongoing. The major unknown is whether those elemental signatures would still be present in adults 4 to 5 years out. The technique works for juvenile identification; it is unknown if the signature is maintained in adult fish. Truscott said that at this time, collections at Wells Dam cannot distinguish the stocks of natural origin fish. He said that CCT doesn't want Okanogan River fish to be incidentally collected for Methow brood. Tom Kahler clarified that not all fish are encountered at Wells Dam because there are two ladders and trapping may not be in operation every day at both ladders.
- *Mike Tonseth will ask Andrew Murdoch for interim pre-spawn mortality data for spring Chinook salmon to incorporate into the 2019 Broodstock Collection Protocols (Item II-B).*
  Tonseth said this item is complete. Tonseth has asked for an update from Murdoch. Tonseth said that some values are available for gross management decisions, but that data are not refined for use in the analysis for recalculating the size of the Wenatchee spring Chinook conservation programs.
- *Larissa Rohrbach will add the size of upper Columbia River conservation programs as a periodic agenda item (Item II-C).*
  Rohrbach said this item is ongoing.
- *Mike Tonseth will ask Andrew Murdoch to provide to the PUDs a list of passive integrated transponder (PIT)-tag arrays that will be shut down if not funded, the cost to operate and maintain these arrays, and the cost of PIT tagging steelhead at the Priest Rapids Dam Off-Ladder Adult Fish Trap (OLAFT; Item II-D).*
  Tonseth said this item is ongoing. Tonseth said he will send this information to the PUDs within 4 to 5 days following the meeting and will inform the HCs when it has been distributed.
- *Larissa Rohrbach will draft email distribution lists merging HCP-HCs and PRCC HSC recipients for review and approval by the HCP-HCs and PRCC HSC and the HCP Coordinating Committees (Item II-E).*
  Rohrbach said this item is complete. This item will be discussed in today's meeting. (Note: documents were emailed by Rohrbach to the HCP-HCs and PRCC HSC on February 7, 2019.)
- *Larissa Rohrbach and Tracy Hillman will revise and distribute meeting protocols for the HCP-HCs and PRCC HSC for review and approval (Item II-E).*
  Rohrbach said this item is complete. This item will be discussed in today's meeting. (Note: documents were emailed by Rohrbach to the HCP-HCs and PRCC HSC on February 7, 2019.)
- *Tracy Hillman will send the Statement of Agreement (SOA) regarding conflicts of interest to Larissa Rohrbach for inclusion of language in the meeting protocols (Item II-E).*

Rohrbach said this item is complete. This item will be discussed in today's meeting. Hillman said a question was raised about whether there is still a need for a Conflict of Interest SOA. Bill Gale said there should be some written agreement for people in the future to reference but does not have to be a formal SOA. Hillman agreed that it could be a simple paragraph within the meeting protocols. (Note: The most recent Conflict of Interest Policy, dated January 26, 2013, was emailed by Hillman to Rohrbach on January 17, 2019.)

Wells Hatchery Committee

- *Greg Mackey will provide a revised version of Douglas PUD's draft 2019 Monitoring and Evaluation (M&E) Implementation Plan for HCP-HCs approval by email (Item III-A).*
  Mackey said this item is ongoing. This item will be discussed in today's meeting.

II. Joint HCP-HCs and PRCC HSC

A. Broodstock Collection Protocols Review (Mike Tonseth)

Mike Tonseth asked that written comments on the Draft 2019 Broodstock Collection Protocols be returned to him by Friday, March 1, 2019, to flag outstanding issues and return a second draft to HCP-HCs and PRCC HSC representatives a few days ahead of the March 11, 2019 special conference call. Bill Gale asked when U.S. Fish and Wildlife Service (USFWS) Ecological Services will be asked to review protocols relative to the Bull Trout Biological Opinions or Bull Trout permit constraints. Gale said review by Sierra Franks at USFWS Ecological Services is needed because approval by the HCs assumes there is Endangered Species Act coverage for impacts of the broodstock collection activities on listed species. Tonseth said ideally USFWS Ecological Services would comment on the plan now.

Tonseth said major changes to the Broodstock Collection Protocols include the following:

- Much of the technical content has been moved to appendices.
  Notables that were bulleted in the front of the document that have been carried over from year to year have been eliminated. Those that are important for this year have been maintained.

Tonseth further explained several bulleted notables. Tracy Hillman recorded edits to the bulleted notables during the meeting for Tonseth to carry through in revisions to the rest of the document.

Elimination of a Fall Collection Component for the Methow Safety-Net and Okanogan Steelhead Programs

Tonseth proposed to eliminate fall steelhead collection (adult hatchery steelhead collection for the Methow Safety-Net and Okanogan programs at Wells Dam and hatchery). Tonseth said there has always been a surplus of fish for the Methow Safety-Net and Okanogan programs. He said there are opportunities to use traps at Wells Hatchery in the spring to collect more spawners instead of fall collection. It has become laborious to deal with overages every year – requiring Wells hatchery to rear fish that turn out to be surplus to program needs and for WDFW to identify bodies of water for fish to be transferred to and coordinating fish transfers, and Wells Hatchery and WDFW staff must then stock out the surplus fish. Kirk Truscott said another problem is that spawners collected in the fall do spawn earlier so they are unable to mate with fish collected in spring. Truscott will review this with his staff to confirm, but preliminarily agrees he would accept ending collection in the fall. He said even during the poorest years, at least 58 fish (the target number) can be collected in the Wells volunteer channel in the spring. Tonseth said they will still read CWTs to identify return origin so that those identified as Okanogan can still be allocated to that program.

Expansion of Spring Chinook Salmon Collection at Wells East and West Ladder Traps

Tonseth said this is actually continuation of an ongoing broodstock collection strategy.

Appendix Review

Tonseth said ideally the appendices can be rolled over year-to-year. Tonseth asked representatives to review the following appendices:

- Appendix I – Summarizes all juvenile rearing and release plans. Tonseth said that if a program is not identified, the plans are status quo. Tonseth asked that representatives ensure all plans are up to date.
- Appendix J – Summarizes summer and spring Chinook salmon disease management at Eastbank Hatchery. Tonseth said there are minor language changes. He said fish are being inoculated with Draxin. He said inoculation by Oxytet will be used on an as needed basis for *Columnaris* only.
- Appendix K – Summarizes Yakama Nation (YN) coho salmon protocols provided by Keely Murdoch. Tom Kahler noticed there is no Douglas PUD plan for coho salmon collection though it is a component of the program. Greg Mackey will provide revisions in written comments on the Broodstock Collection Protocols.
- Appendix G – Summarizes the management plan for managing surplus juvenile spring Chinook salmon and summer steelhead. Tonseth asked the representatives to ensure that past discussions have been accurately captured for managing overages. Tonseth said these plans were in last year's Broodstock Collection Protocols in the body of the document. He said there were revisions to language for this year.
- Appendix H – Summarizes continued inclusion of a plan in place for the 2018 Methow conservation steelhead brood. Tonseth said that last year some parts of the plan were not

followed. He said the existing plan was carried forward with the note that the plan will be followed this year. He said the plan was contingent on NOR collection by hook-and-line in the Methow basin and that last year an overage was collected by hook-and-line. He said this may be more challenging this year due to low numbers of returning adults. Tonseth asked when the collection would start. Matt Cooper and Mackey said it would have started already if the river temperatures were warmer, and that it will start as soon as the weather changes and the river is thawed.

Chelan Falls Broodstock Collection at Wells Dam Volunteer Trap

Tonseth said there were changes to broodstock collection for the Chelan Falls summer Chinook salmon program. Tonseth asked Catherine Willard to clarify the changes.

Willard said that for three years, Chelan PUD piloted broodstock collection at the Chelan River Canal Trap. She said in the first year all 100 fish were collected; however, second- and third-year collections were interrupted by other activities (gravel augmentation, outage). This year, a new Washington Administrative Code changed safety precautions making the Chelan River Trap infeasible to operate without major, expensive modifications.

Willard said Chelan PUD will prioritize collection at the Wells Dam Volunteer Trap while concurrently piloting a temporary weir located in the Chelan River Habitat Channel and collection by beach seine in the Chelan Falls spawning channel. Tonseth said there will need to be coordination with brood collection at Wells Hatchery program to ensure collection at the volunteer trap for the Chelan Falls program occurs within the same trapping period as brood for the Wells summer Chinook programs. Truscott said they haven’t determined details on the timing of weir installation and beach seining activities. Tonseth said any broodstock collected should be retained, but those collected later in the season are less likely to be used due to higher disease potential (BKD, *Columnaris*) and lower egg quality.

Gale said he is concerned about entering into a long-term agreement that Wells Dam is always going to provide the backstop for Chelan Falls. Willard and Tonseth agreed the long-term commitment is to collect broodstock for the Chelan Falls program in the Chelan River. Truscott said it’s unlikely that collection at Chief Joseph Hatchery would be done to back-fill summer Chinook salmon programs. He said by design there are few fish collected there in order to support tribal harvest programs and it is unlikely that CCT would support collection. Tonseth said he will revise the protocol to state that the HCs will discuss alternative options if collection in the Chelan River falls short of target numbers.

Collection of Surplus Broodstock

Gale said that the USFWS Regional Office is formulating a more defined policy for how USFWS handles requests for surplus fish. He said it will require a formal request to the regional administration, rather than simply being handled by local USFWS staff, and this may make the disposition of surplus fish more complicated.

Tonseth said that in the past, protocols were written to ensure broodstock were collected throughout the return run. This year, returns will be so low all fish should be collected early in the run regardless of weekly targets to ensure meeting broodstock goals, instead of trying to distribute collections throughout the run and perhaps not collection enough fish. Tonseth recommended taking early advantage of the collection days and sites available, noting it is not something normally advocated by the HC, but may be a prudent action. This has not been written into the 2019 protocols yet. Tonseth requested that representatives discuss adding this to this year's protocols. Todd Pearsons asked which programs may be affected by low numbers. Tonseth said the spring and summer Chinook salmon programs will have low numbers. Truscott said they had to incorporate hatchery-origin fish at Chief Joseph Hatchery last year as well. Tonseth said he will review last year's data to determine whether all trapping opportunities and locations were well utilized.

Tonseth said in the Wenatchee River, depending on early summer flows and the low expected summer run forecast, the Dryden Traps may not be very efficient. He said there may be a need to collect summer Chinook salmon at Tumwater and Dryden dams simultaneously in 2019 rather than rely on weekly collection quotas or only going to Tumwater Dam once a deficit in brood numbers occurs at Dryden. Truscott asked whether NOR fish arriving at Dryden early in the season would be returned to the river. Tonseth said no, typically collection is frontloaded, but in years of low returns there is a deficit at Dryden and numbers are made up at Tumwater later. Pearsons asked if they are only proposing to retain NOR fish for broodstock (pNOB). Tonseth said yes, the program would just deviate from use of a weekly collection quota and would retain any NO adult summer Chinook as it is encountered at either Dryden or Tumwater Dams. He does not expect that for this brood year, not collecting broodstock throughout the return will cause long-term harm to the population.

Collection of Chinook Salmon to Support Chief Joseph Hatchery

Tonseth said that the Chief Joseph Hatchery may collect summer Chinook brood at Wells Dam if needed. Pearsons asked if this has ever been done. Tonseth answered that this has never been done before, but this year it could, if adult returns to Chief Joseph Hatchery fall short of broodstock targets.

Tonseth said adipose-clipped only (no CWT) spring Chinook encountered at Methow Hatchery or WNFH could be transferred to the Chief Joseph Hatchery CCT segregated program. Gale asked whether the assumption that it is a Chief Joseph Hatchery fish is correct or if it could be a wire-shed from an Endangered Species Act-listed program—how would you know? Gale said he is unsure if it is permitted to make that transfer of a 'wire-shed' fish to Chief Joseph Hatchery (CCT segregated program, which is a program for harvest). Gale said it would be rare but if it is a realistic occurrence, USFWS and CCT are at risk of moving fish that are not permitted for use in the Chief Joseph Hatchery segregated program. Tonseth asked Truscott to review this bullet to determine if this language should be kept and if it would be permitted to cross ESA-listed fish with a Chief Joseph Hatchery CCT segregated program fish.

Collection of Summer Chinook Salmon at Wells Hatchery for the Yakama Nation Yakima River Program

Tonseth asked Keely Murdoch and Truscott to review the collection of summer Chinook salmon from the Wells Hatchery Volunteer Channel to support the YN's Yakima River summer Chinook salmon program. Draft protocols identify up to 350,000 eggs could be transferred assuming 300,000 juveniles would be released. Brood may not be collected for that program due to differing positions between the CCT and the YN. Tonseth would like to know whether the YN will collect those fish so that, in the event that they will not be collected, they can be allocated elsewhere (e.g., for food). Truscott agreed it is difficult to justify moving fish from Wells to the Yakima program.

Murdoch suggested establishing the following priorities in the Broodstock Collection Protocols for allocation of broodstock collected at Wells Dam: 1) Wells Hatchery program; 2) other upper Columbia River programs; 3) the Yakima program. Gale asked whether these transfers are always occurring as eggs. Murdoch said yes, transfers are made as green eggs (gametes). Gale said USFWS is getting requests for fish from many sources and appreciates the effort to prioritize. Kahler agreed this allows for coordinating collection at the Wells volunteer ladder where holding surplus fish is undesirable. Gale asked what the YN summer Chinook salmon program size is. Murdoch said 250,000 eggs could be requested from sites where available, and the Hatchery and Genetic Management Plan (HGMP) says up to 400,000 eggs could be collected.

Murdoch said that Melinda Goudy (YN) provided a presentation and answered questions about developing a local broodstock but explained there wasn't a good opportunity to collect in the Yakima River. She said Goudy took the questions from this committee and had a meeting with staff in the Yakima Basin who decided to start releasing smolts at Prosser Dam to have a collection point for returning adults to develop a local broodstock. Murdoch said additional eggs were requested last year to meet this need. She said that now there is a release site (Prosser) specifically to support local broodstock development, this is similar to the way the coho reintroduction project has approached local broodstock development in the Wenatchee Basin, with releases from Leavenworth NFH.

Gale requested some certainty around the number of eggs that could be requested by the program this year. Murdoch stated the goal of 300,000 juveniles may have changed since last fall to include a release group for Prosser. Gale noted there were enough adults last year at Entiat to support the Yakima program but with the contingency that early returning fish will be prioritized for consumption, late returning fish seem to meet the Yakima needs just fine. Murdoch read an email from Goudy stating that the original release goal of summer Chinook salmon in the Yakima Basin was 500,000 and is still the goal. Goudy said that initial years focused on 250,000 with an emphasis on jump-starting collection at Prosser Dam. Murdoch said the release at acclimation sites is still part of the plan. Murdoch said to differentiate summer and fall Chinook salmon collected at Prosser Dam, 100% of the summer Chinook salmon will be tagged with CWTs, and 100% of fall Chinook salmon will be adipose-fin-clipped. Murdoch will confirm with YN staff the total number requested. Gale asked that the Broodstock Collection Protocols state the specific number requested from each hatchery or define priorities for review by the USFWS Regional Office.

Operating Tumwater Trap to Facilitate Lamprey Passage

Tonseth asked that representatives review to ensure protocols are acceptable to the HCs.

Appendix B – Marking Rates

Tonseth asked that representatives review to ensure protocols are acceptable to the HCs.

Appendix C – Return Year Adult Management Plans

Tonseth said he will distribute Appendix C in the coming days.

Appendix A – Biological Assumptions

Tonseth said a second table was added that responds to feedback on the number of adults and egg targets. This will help determine if there may be an overage or underage for a program. Table 2 may need revision based on discussion of the spring Chinook salmon broodstock collection plan. Tonseth noted these targets are program-specific. Gale asked whether Tonseth has all information needed from USFWS. Tonseth answered the necessary information is typically in Appendix B and some information for steelhead programs upstream from Wells Dam is integrated in the steelhead plan.

Allocation of Smolts in the Nason Creek Conservation Program and Safety-Net Program

Tonseth presented an interim reduction of Nason Creek spring Chinook salmon conservation program (wild parents) size to 100,000 juveniles and increase in safety-net program (hatchery parents) size to 123,670 (see page 19, Table 10 of draft Broodstock Collection Protocol).

Tonseth said 490 wild spring Chinook salmon returns and 2,966 hatchery returns are expected upstream from Tumwater (Table 9). Matt Cooper asked whether that estimate seems high for hatchery returns. Gale said expecting approximately 3,500 fish to return from a 450,000 smolt release would be a smolt-to-adult return ratio that seems high. Tonseth agreed and said WDFW's model tends to over-predict hatchery returns but has generally been accurate for wild returns. Tonseth said he may use a correction factor to adjust these numbers based on last year's results.

Pearsons asked whether the PUDs are using too many NOR fish to maintain their programs and if there are truly that many hatchery returns, won't there still be some hatchery fish removed at Tumwater? Tonseth reminded the HCs that when using the sliding scale system, the target PNI shifts. Cooper asked whether the NO run size can be tracked in season. Tonseth said NORs cannot be tracked very well in season because only approximately 25 to 30 NO PIT tags may return, mostly from the Chiwawa and only a couple from Nason, which is a low number for expanding to total return in season.

Tonseth said the bigger issue in need of discussion is reducing the size of the Nason conservation program of 125,000 fish to 100,000 in light of low expected NO returns in 2019.[3] Murdoch said that YN did not agree to reducing the conservation program size based on broodstock origin. When insufficient NOR returns are available, hatchery origin fish are intended to be used in the conservation program. The number of wild fish extracted for broodstock would not change over what is proposed in the protocols, rather, hatchery fish should be used to back-fill the conservation program (and would be adipose fin-present). Tonseth said offspring of hatchery parents could be allocated to the safety-net program and would be marked as safety-net program fish are. Tonseth said this would not be a proposal to change US v Oregon but would provide a notice to change marking within HCP and settlement agreement programs. Gale said this may affect the federal programs. Truscott said Nason Creek conservation program juveniles are currently adipose-fin-present and tagged in the body with CWTs, but they could be tagged with wire differently.

Truscott said the discussion is about how to mark 25,000 juvenile fish that have hatchery-origin adults but will be marked as a conservation program fish; how important is it to manage a small number of adults (250 adults) resulting from this group? Truscott asked how important it is to prioritize wild x wild progeny over hatchery x hatchery progeny on spawning grounds? Murdoch answered there is no rule in the Nason conservation program to prioritize wild x wild progeny on the spawning ground but that it's going to be increasingly important to manage safety-net fish (hatchery x hatchery progeny) on the spawning grounds. Tonseth agreed but said in years of high abundance a lot of hatchery x hatchery progeny would have to be removed to prioritize wild x wild progeny on

[3] Reduction of the conservation program would not change the overall production obligation for Nason Creek.

the spawning grounds. Murdoch suggests deferring to the management plan that states that conservation program fish would be adipose-fin-present, conservation fish would be recycled back into the program, and if there are not enough conservation fish, safety-net fish would be used but all would be marked adipose-fin-present if they are a conservation program fish. The intent is to avoid the previous management approach of a floating program size based on return size. Pearsons asked for clarification—are we talking about flexing the size of the conservation and safety-net programs? Murdoch answered no, we are not talking about flexing the programs annually, but if we are talking about reducing the conservation program size, more approval will be needed at higher levels of management. Tonseth said he doesn't think the conservation program size will change much this year. Murdoch noted there could be a limited number of natural-origin adults (58), and the remainder of the broodstock to meet the conservation program would be backfilled with adult returns from the conservation program. Murdoch and Gale noted one of the management strategies of the programs is to backfill the program with hatchery fish so as not to reduce the program size.

Hillman said he thought the spreadsheet model, which was partially updated and distributed by Murdoch in January, would be used to determine the number of fish allocated to the conservation and safety-net programs. However, the model still needs addition information and results from the model have not yet been approved by the committees. Thus, Hillman asked if it is premature to identify changes to the number of fish in the conservation and safety-net programs. Tonseth agreed this represents an interim reduction in conservation program number. Tonseth requested time to rerun the escapement estimates and revisit the management plans to ensure they are in agreement on number of fish per program and marking of those fish, and then revise the language in the protocol so it isn't framed as a reduction in size of the conservation program.

Pearsons asked why there would be resistance to moving all conservation NOR fish into the broodstock collection and back-filling from the safety-net program. Murdoch said there is a history of limiting conservation program size due to limited number of NOR fish for the broodstock. She said a review of the program was done in the past to make clear that all fish used for the conservation program should be adipose-fin-present. She said that now we are meeting production goals but potentially altering the marking of program fish. Pearsons said there is no disagreement that the aggregate program size should be met but potentially a disagreement about marking.

Gale said changes to program size should be something that should be discussed separately, and potentially a separate SOA. Gale said changes in production and marking targets for each component of the aggregate program should be decided outside the broodstock collection protocols and then will need to be discussed in the US v Oregon arena before implementation. Pearsons thought this committee should be able to make decisions and inform US v Oregon and that US v Oregon should not influence decision making for this group. Gale partially agreed, but decisions that deviate from US v Oregon agreements need to be memorialized somewhere other than within broodstock collection protocols.

Truscott said he would be concerned about reducing the size of the conservation program (fish that are afforded the most protection) because of low return predictions. Other tagging options could be explored that allow for adult management at Tumwater Dam and protection from harvest.

Willard said if hatchery x hatchery fish are adipose-fin-present, how does that affect PNI? Murdoch said they are still marked with CWTs. Thus, they will be identified as hatchery fish when they are collected for broodstock prior to using the multi-population PNI model. Tonseth said the multi-population PNI model is not a requirement in the Wenatchee permit, as it is in the Methow Basin.

Brett Farman said NMFS now has models that do compensate for differing program types (i.e., safety-net and conservation programs to adjust PNI). Farman will work with Charlene Hurst and Tonseth to explore different inputs in the models. Farman said changes to program allocation would require approval by the HCs.

Hillman summarized that there are two issues to research and discuss further: 1) is there a need to change allocations for conservation and safety-net programs (this should be decided outside the broodstock collection protocols); and 2) how fish within each program (conservation and safety-net) are to be marked.

B. Streamlining

Tracy Hillman asked representatives to provide comments on meeting coordination documents to himself and Larissa Rohrbach over email. Final versions of the distribution lists and meeting protocols will be brought to the HCP-Coordinating Committee and the Priest Rapids Coordinating Committee.

C. NMFS Consultation Update

Brett Farman said the Methow Steelhead permit has been drafted and is in review. He said once the EA is completed, the EA and both Wells and WNFH HGMPs will go out for comment. Tom Kahler asked when the EA will be published. Farman said the Methow Steelhead EA is in line behind some other projects with no expected publication date. He said the comment period will be 30 days. Bill Gale asked why the WNFH Steelhead HGMP is going out for public comment; he thought it had already gone out for public comment. Farman confirmed that typically HGMPs go out at the same time as EAs for public comment. He said the Winthrop Steelhead HGMP does need to go out for public comment as part of the EA but noted they typically receive no comments on the HGMPs.

Farman said Emi Kondo (NMFS) asked about the status of the Wenatchee summer Chinook HGMP submission for the unlisted Chinook salmon bundle. Deanne Pavlik-Kunkel (Grant PUD) answered that the cover letter is waiting to be signed and once it is signed it will be sent to NMFS. Farman said the unlisted Chinook salmon bundle EA is ready for publication and will be posted once the HGMP is received. He said the EA may not be published immediately due to a backlog from the January 2019 furlough. Todd Pearsons asked about the review and timing of the draft unlisted Chinook salmon bundle permit. Farman confirmed that the unlisted Chinook salmon permits are out for review by general council. Once revised per the internal review, they will be made available for public comment.

Farman said Charlene Hurst asked whether bull trout information is being collected. Catherine Willard said yes. Chelan PUD talked to Karl Halupka (USFWS) prior to his retirement and stated that this information will be included in annual reports. Halupka indicated he was comfortable changing the due date for bull trout reporting from September to correspond to the PUD's annual reporting timeline. Gale confirmed that those annual reports will be sent to USFWS Ecological Services. Gale asked if bull trout reporting is being tracked in the Methow because it has not been a requirement but should be accounted for somehow. Kahler answered that Andrew Gingrich (Douglas PUD) has reported on bull trout take (e.g. due to trapping) in an annual report that goes to Steve Lewis (USFWS) for the Bull Trout Management Plan. Gale asked whether angling encounters were coordinated with USFWS to avoid double counting. Tonseth confirmed there will be an appendix in the annual PUD report documenting bull trout encounters.

III. Wells Hatchery Committee

A. Wells Monitoring and Evaluation Implementation Plan

Greg Mackey explained that Douglas PUD has not accepted the most recent revisions to the Wells M&E Implementation Plan made by Keely Murdoch because of uncertainty around the methods to be used for estimating brood year 2020 steelhead escapement (first discussed in the January 16, 2019 HCP-HCs and PRCC HSC meeting). Tracy Hillman suggested making the language added by Murdoch more specific. Kahler proposed first receiving information on the issues creating uncertainty (costs of PIT-tagging at the OLAFT and operating and maintaining PIT arrays that may not be covered by WDFW). Then, Douglas PUD would consider this internally before revising the language in the Wells M&E Implementation Plan. It would then go to the Wells HC for a final vote.

Mike Tonseth asked about the HCP-HCs protocol for voting on decision items. Tom Kahler said the Chair can grant each party one 5-day extension to the typical review period prior to voting on a decision item. If the voting party does not vote within the 5-day extension period, the committee assumes the silent party abstains from voting. In this case, the revised version of the Wells M&E Implementation Plan has not yet been reissued as a decision item. Kirk Truscott noted that had a different methodology of estimating steelhead spawner abundance without use of PIT tags been proposed in any of the draft M&E Implementation Plans, CCT may not have approved them. Bill Gale asked if a change to these methods would bring all the M&E Implementation Plans up for a re-vote and all representatives confirmed that it would. (Chelan PUD's 2019 M&E Plan was modified and approved in the meeting on August 15, 2018.)

Mackey said Douglas PUD has not been using the WDFW steelhead escapement model based on tagging at the OLAFT. Rather, they PIT tag steelhead at Wells Dam and recapture (detect PIT tags) at arrays within the Methow River basin. Hillman asked whether results from the two different models have been compared. Mackey said no, because the WDFW model is not readily available and has only been shown to the committees in a presentation from Andrew Murdoch. Mackey said having the WDFW model published would allow Douglas PUD to evaluate whether the WDFW model could be used for the Methow River and, if so, rescope their M&E Implementation Plan. Tonseth will ask Andrew Murdoch to share WDFW's internal comparison between model outputs.

Truscott said PIT tagging steelhead at the OLAFT is key to accurate spawner escapement estimates in the Okanogan River. Truscott said that if PIT tagging at the OLAFT is not funded by WDFW, CCT would preferentially support funding the PIT tagging at the OLAFT versus funding certain arrays.

Gale asked whether the O&M and replacement costs for arrays is being divided between steelhead and spring Chinook salmon. Tonseth said operation for tracking spring Chinook salmon would be three months whereas arrays must be operational nearly year-round to track steelhead and therefore would be more costly.

Kahler asked what were the Bonneville Power Administration's (BPA's) goals for installation of the PIT arrays originally? Kahler asked if there is a need for an Independent Scientific Review Panel review of WDFW's proposal (to shift from PIT tagging steelhead to spring Chinook salmon). What is BPA's opinion on how these arrays are managed? Do they consider these arrays valuable for steelhead and spring Chinook salmon? Tonseth answered that WDFW has latitude to apply the funding to its objectives and may have already moved toward modifying the scope of the use of the BPA funding from supporting steelhead PIT tagging at OLAFT or PIT array O&M to working on the spring Chinook salmon escapement model.

Hillman reminded the HCs representatives of an outstanding action item for WDFW, which is to provide the PUDs with the cost of PIT tagging at the OLAFT, cost of array O&M, and providing a list of arrays at risk of being turned off. Todd Pearsons asked for clarification on what "turning off" arrays means? Pearsons asked what the cost would be of allowing automated arrays to continue to run. Tonseth answered that "turning off" an array means that no future data management would be provided and no O&M would be provided for those that are not automated (e.g., those running on generators).

Kahler noted that there is no certainty that BPA will agree with WDFW's proposed switch to modeling spring Chinook salmon. Kahler asked what the rationale is for PIT tagging spring Chinook salmon. What is achieved by creating a spring Chinook salmon spawner escapement model that differs from existing methods (e.g., spawning ground surveys and carcass surveys)? Tonseth said a PIT-tag-based model will improve accuracy of the escapement estimates. Willard noted that spring Chinook escapement estimates above Tumwater are already corrected to improve accuracy. Keely Murdoch said a PIT-tag-based model gives run escapement for each of the tributaries allowing for better estimates of pre-spawn mortality (not spawning escapement). Kahler said all spring Chinook salmon are still handled at Tumwater and Wells dams; adding another handling point at Priest Rapids could significantly contribute to pre-spawn mortality.

The PUDs and USFWS have remaining questions about the utility of shifting effort from steelhead to spring Chinook salmon. Tonseth will invite Andrew Murdoch to the next meeting to answer questions about the goals of switching from PIT tagging steelhead to spring Chinook salmon at the OLAFT.

B. Wells HCP Action Plan (Tom Kahler)

Tom Kahler presented the Draft 2019 Wells HCP Action Plan to the Wells HC (Attachment B) and noted additions compared to previous years. Kahler said he will reissue an updated version following the meeting and Wells HC members will respond with feedback to Mackey by February 21, 2019.

C. Job Opening (Greg Mackey)

Greg Mackey said that Douglas PUD has an open position at the Wells Hatchery for a Hatchery Specialist and asked HCP-HCs and PRCC HSC representatives to let potential candidates know. He said the job listing is posted on the Douglas PUD website and applicants can be referred to him. Kirk Truscott asked about the level of expertise. Mackey said this is a high-level technician position that reports directly to Pat Phillips (Douglas PUD). Mackey said the job is open until enough qualified applications have been collected and the position is filled.

IV. RR and RI HCs

A. Action Plan (Catherine Willard)

Catherine Willard presented the Draft 2019 Chelan PUD Action Plan (Attachment C) and noted the additions compared to previous years and identified the timing of events. Rocky Reach and Rock Island HCs representatives have 30 days to review the plan. Representatives will send comments to Willard by March 13, 2019.

B. Tumwater Dam Fishway Update

Catherine Willard said the concrete core samples showed that erosion is not as bad as previously thought at the Tumwater Dam Fishway and no repair work is necessary at this time. Mike Tonseth asked when the ladder would be re-watered. Willard said that it was not de-watered.

V. PRCC HSC

A. Approve the January 16, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the draft January 16, 2019 meeting minutes as revised.

HCP-HCs and PRCC HSC members agreed that in most meetings, all the minutes (HCP-HCs and PRCC HSC) can be revised and approved at the same time. Pearsons noted for the record it needs to be clear when representatives are approving PRCC HSC minutes at the beginning of meetings.

B. Broodstock Collection Protocols for PRCC HSC Programs

Mike Tonseth explained several bulleted notables in the draft broodstock collection protocol pertaining to the PRCC HSC programs.

Carlton Summer Chinook Salmon

Tonseth said given the low expected natural-origin summer Chinook return, the Methow summer Chinook salmon program (Carlton Summer Chinook salmon; Grant PUD program may have difficulty in meeting the 2019 collection target under past trapping protocols where a weekly collection quota was used. NOR brood and protocols could be revised to take advantage of fish in hand during collection at Wells Hatchery if supported by the HSC. He said the target would be a seasonal goal rather than weekly collection goals.

Todd Pearsons said there may be a revision needed to target a higher number for the Carlton summer Chinook salmon program, with target numbers that are more similar to last year. Todd Pearsons said that Eric Lauver (Grant PUD) said they have not met targets for several years. Tonseth said there was a higher number of Chinook salmon collected in 2018 based on dramatically lower than expected fecundities in the 2017 brood. Based on production assumptions, the number recommended should be sufficient for 2019. Pearsons said the program is flush this year because they took 68 (136 total) instead of 61 adults per gender in 2017 but that there was under-collection in previous years. Tonseth said that based on the eyed egg count the program is bumping up against the 110% production limit and he does not want to increase the number collected to avoid producing a surplus. Tonseth said he will review the assumptions and numbers to determine if the target number could increase. Pearsons said if it fits the program assumptions, he supports changing the targets to the number collected last year.

Fall Chinook Trapping at the OLAFT

Tonseth said WDFW has proposed to eliminate trapping fall Chinook salmon at the OLAFT and increase effort from hook-and-line collection (Angler Broodstock Collection or ABC effort) in this years broodstock collection protocols. This year fall Chinook salmon returns to the lower Columbia are predicted to be some of the lowest on record. WDFW has opted not to advocate for collection of fall Chinook salmon at the OLAFT to reduce impact to NOR spawning aggregates upstream from Priest Rapids. Pearsons noted that predicted runs back to the Hanford Reach are not anywhere near the historical lows and that predictions indicate that escapement targets will be met. Tonseth said for aggregates above the Hanford Reach we know very little about the predicted run size. Pearsons said the proposed elimination of OLAFT collections was a surprise because Grant PUD relies on handling at the OLAFT for collection for PNI. This is a substantial change to the program that is being introduced in the broodstock collection protocols without discussion in the HSC. Broodstock collection protocols should reflect changes that have been discussed previously and should not be a surprise to the programs. Tonseth said fall Chinook salmon forecasts were not available until January. Pearsons said there is a tradeoff between passing fall Chinook salmon past the OLAFT versus meeting the PNI targets at Priest Rapids hatchery program and the Hanford Reach. Pearsons said there is an expectation that we will meet our brood targets but may not meet PNI targets. He said the PNI target may not be met for the Hanford Reach without the use of the OLAFT in large part because of the low pNOB in the U.S. Army Corps of Engineers' program. The pNOB of the PRH program boosts the PNI for the Hanford Reach substantially.

Matt Cooper asked whether the ABC effort could be as successful as it was last year. Pearsons said if the fishery is as successful as last year, collection at the OLAFT is probably not needed. Pearsons said Paul Hoffarth (WDFW) suggests the collection rate in the ABC fishery may not be as successful and Grant PUD should assume approximately 500 fish could be collected. Pearsons said Hoffarth is not comfortable closing the harvest fishery early, which is what allowed for large numbers for broodstock collection last year. Tonseth said WDFW needs to protect spawning aggregates moving upstream by minimizing collection at downstream points such as the OLAFT. Kirk Truscott agrees that protecting some of the upstream spawning aggregates would be even more important with climate change. Pearsons said the tradeoff is allowing fall Chinook salmon to pass Priest Rapids versus collection at the OLAFT. Pearsons noted that last year was even more of a concern because the predicted run size was smaller than this year and yet full escapement was met. Tonseth said fish probably should not have been collected at the OLAFT last year either. Truscott suggests Tonseth go back to WDFW to attempt to enhance collection in the ABC fishery.

Bill Gale said collecting sufficient NOR brood (in the fishery or the OLAFT) is one piece of PNI management but the other piece is management of the proportion of hatchery origin spawners (pHOS) on the spawning ground. How does this affect our ability to manage fish on the spawning ground? Pearsons said that pHOS has been very good (~10%). Pearsons said last year the volunteer trap was run as long as was able because the trap wasn't becoming filled. He added the U.S. Army Corps of Engineers has also been keeping the trap open to bring fish into Ringold. Tonseth said Ringold made improvements to their trap that will enhance their ability to bring adults into the trap. Pearsons said Ringold typically doesn't get a lot of NORs. Pearsons said he is not opposed to collection by ABC if Paul Hoffarth is comfortable with it. He said there will be additional transfer boats and trucks allocated this year to improve collection and transfer, and there will be a high cap on participants (100 boats).

Pearsons said he will organize a conference call with himself, Tonseth, and Hoffarth to develop a plan to present to the PRCC HSC. Pearsons asked if the plan is to maintain collection at the OLAFT, will Truscott approve knowing CCTs aversion to trapping at the OLAFT. Truscott said the later arriving fish may be the most important to the Okanogan. Truscott said he will have a hard time buying into the status quo (1,000 fish at OLAFT) but that it would be more acceptable to collect half as many at the OLAFT (500 fish). Keely Murdoch said she wants to make sure that enough broodstock can be collected and will be interested to know how the conversations develop. She said there is no preference for whether the fish come from ABC or the OLAFT. Pearsons said the broodstock needs can be met by using the hatchery channel. Tonseth said the concern is not meeting production goals but pNOB [PNI goal] for the Hanford Reach. Tonseth said that low pHOS helps the PNI. Pearsons said there were many fish collected last year in the ABC allowing spawning combinations of 1:1, 1:2, and 1:4.

C. Priest Rapids Monitoring and Evaluation Implementation Plan

Todd Pearsons will distribute the draft 2019 Priest Rapids M&E Implementation plan to the PRCC HSC this week or next week for a 30-day review. He said highlights and changes to the plan will be shown as using track changes. He said the following changes will be made:

- An ABC task will be moved from M&E to O&M
- Removal of a completed task related to CWTs and carcass bias. This task will be summarized in the comprehensive report and annual updates have been included in the M&E annual reports

VI. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are on February 20, 2019 (Grant PUD), a conference call on March 11, 2019, and March 20, 2019 (Grant PUD).

The HCP-HCs and PRCC HSC will hold the special conference call on March 11, 2019, to discuss revisions to the first draft of the 2019 Broodstock Collection Protocols. Mike Tonseth will receive comments on the first draft by March 1, 2019, then will send around a revised draft with redlines shown in track changes and a clean copy by March 6, 2019. Tonseth requested that representatives make revisions to the clean copy. The goal will be for the HCP-HCs and PRCC HSC to approve the 2019 Broodstock Collection Protocols in the March 20, 2019 meeting.

FINAL 2019 ACTION PLAN
WELLS HCP

WELLS HCP COORDINATING COMMITTEE

1. **Juvenile Fish Bypass**
   a. Gas Abatement Plan (GAP) and Bypass Operating Plan (BOP) to CC...... 18 January 2019
   b. CC comments on GAP/BOP to DCPUD .... 12 February 2019
   c. CC approval of GAP/BOP .... 21 February 2019
   d. Submit final GAP/BOP to FERC for approval .... 28 February 2019
   e. 2019 Bypass operations at Wells .... 9 April 2019 – 19 August 2019

2. **Annual Monitoring of Juvenile Migration Run Timing**
   a. 2019 draft passage-dates analysis and post-season bypass report to CC.........October 2019
   b. CC approval of 2019 final report ....November 2019

3. **Fishway Outage Schedule for Fishway Inspection, Maintenance, and Fishway Projects**
   a. West Fishway.. 12 February 2019 – 28 February 2019
   b. East Fishway .... 7 January – 5 February 2019
   c. Adult Fishway Trap Coordination Meeting .... April 2019

4. **Multi-Year Sub-yearling Chinook Life-history Study**
   a. Draft juvenile life-history report to CC .... April 2019
   b. Final juvenile life-history report ....July 2019

5. **Review and Approval of 2019 Hatchery Broodstock Collection Protocol**
   a. Draft protocol to CC for review.. 16 February 2019
   b. CC approval of draft protocol .... 27 March 2019
   c. Deadline for submission of protocol to NMFS... 13 April 2019

6. **Pikeminnow Control Program**
   a. Draft 2018 pikeminnow report to HCP CC .... April 2019
   b. Final 2018 pikeminnow report.. June 2019
   c. 2019 Pikeminnow removal – Wells Project................................ March – November 2019

7. **Avian Protection Plan**
   a. Bird Hazing..April – August 2019

8. **2020 Survival Verification Study**
   a. CC approval of Study Plan .... January 2019
   b. Obtain contract for implementation .... Fall 2019
   c. Obtain/set up equipment and infrastructure for implementation ...... Fall 2019-Spring 2020
   d. Tag study fish...November 2019

9. HCP Annual Report

a. Draft 2018 annual report to DCPUD for review.. 9 January 2019
b. Draft 2018 annual report to CC for 30-day review.................................... 6 February 2019
c. CC comments on draft 2018 report due to Anchor QEA............................... 6 March 2019
d. Final 2018 annual report to DCPUD .... 21 March 2019
e. Final 2018 annual report due to FERC .... 30 March 2019

WELLS HCP HATCHERY COMMITTEE

1. Implement 5-year Hatchery Monitoring and Evaluation (M&E) Plan
- a. Ongoing implementation ....January – December 2019
- b. Draft annual report for 2018 to Douglas PUD ....July 2019
- c. Draft annual report to Hatchery Committee (HC) .... September 2019
- d. Final annual report to HC ....November 2019
- e. Draft 2020 implementation plan to HC ....July 2019
- f. HC approval of final 2020 implementation plan ....October 2019

2. Assessment of Precocial Maturation or Residualism
- a. Methow Hatchery spring Chinook lethal sampling .... March 2019
- b. Wells steelhead visual assessment .... April 2019

3. Twisp Population Study
- a. Implementation (to be determined)...September – October 2019
- b. 2014, 2015, 2016, 2017, 2018 Reports .... June 2019

4. 2019 Broodstock Collection Protocol
- a. Draft to HC for review .... 9 February 2019
- b. HC approval of draft protocols .... 21 March 2019
- c. CC approval of Wells Dam trapping operations................................ 27 March 2019
- d. Deadline for submission to NMFS .... 13 April 2019

5. Annual Implementation – Okanagan Sockeye Fish/Water Management Tools
- a. Water Year 2017-2019...October 2018 – September 2019
- b. Incubation Protection and Emergency Monitoring.............................January – April 2019
- c. Redd Scour Prevention Activities .... April-May 2019
- d. Optimization of Limnetic Rearing Environment .... July-September 2019
- e. Sockeye Spawning Protection Levels .... October-November 2019
- f. Kokanee Elevation and Protection Levels .... October-November 2019
- g. Water Budget (Snowtel, River and Lake Gage, Withdrawals)... January – December 2019

6. Methow Steelhead Relative Reproductive Success Study
- a. Implementation ....March 2010 – December 2021
- b. Annual report on genetic analysis... September/October 2019
- c. Biological data in Annual M&E Report (above) .... September 2019
- d. Final report.. 2021/2022

7. Hatchery Genetic Management Plans
- a. Receive new Wells steelhead hatchery permit................................*to be determined, 2019*
- b. Receive new Wells summer Chinook hatchery permit....................*to be determined, 2019*

8. Chief Joseph Hatchery Production
- a. Fund hatchery production (spring/summer Chinook)..2019
- b. Fund monitoring and evaluation 2019

WELLS HCP TRIBUTARY COMMITTEE

1. **Plan Species Account Annual Contribution**
   a. $176,178 in 1998 dollars ($284,793.79 in 2019 dollars) .... 11 January 2019

2. **Annual Report - Plan Species Account Status**
   a. Submittal of 2018 account-status report to Tributary Committee (TC): ...... 3 January 2019
   b. Integration into 2018 HCP Annual Report: .... January 2019

3. **General Salmon Habitat Program**
   a. Project review and funding .... January-December 2019

4. **Small Project Program**
   a. Project review and funding Decision .... January-December 2019

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: April 18, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the March 11, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Conference Call

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCP) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) conference call was held on Monday, March 11, 2019, from 2:30 p.m. to 4:15 p.m. Attendees are listed in Attachment A to these meeting minutes.

Conference Call Action Items

Joint HCP-HCs and PRCC HSC

- Greg Mackey will forward Douglas PUD's suggested revisions describing broodstock and egg obtainment for the Douglas PUD Coho program (refers to Appendix K of the Protocols) to Keely Murdoch, Bill Gale and Matt Cooper for their review before inclusion in the Broodstock Protocols.
- Mike Tonseth will add language to the Protocols that allows flexibility in the future to select for older males using alternative, non-random mating strategies.
- Mackey will summarize numbers for Committee discussion and make edits to Protocols on the likelihood that all summer steelhead broodstock could be collected at the Wells Volunteer Trap in the spring to eliminate fall-collection for the MSN and Columbia Safety-Net (CSN) programs.
- Tonseth will redistribute the Methow Basin spring Chinook translocation plan for review and discussion in the March 20, 2019 meeting. Tonseth will ask Michael Humling (USFWS) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to WNFH.
- Catherine Willard will send the Relative Reproductive Success (RRS) study extension memorandum to Rohrbach with the translocation plan for distribution *(Rohrbach distributed an email from Willard and the attached RRS study extension and translocation plan to the HCP-HC and PRCC HSC following the March 11, 2019 conference call).*

- Tonseth will confirm with Andrew Murdoch (WDFW) that DNA sampling of the 2018 to 2023 returns is still consistent with the original RRS extension agreement and provide an updated extension.
- Tonseth will send the Methow Basin Steelhead Conservation program broodstock collection protocols by angling to Humling and Snow for review.
- Bill Gale and Cindy Raekes (USFWS) will send suggested edits to Mike Tonseth regarding the Chiwawa Weir operations protocols to optimize operation and protect bull trout per the BiOps.
- Willard will email notes that summarize 2018 Chiwawa Weir operations. *(Willard notified Rohrbach that she emailed details on 2018 Chiwawa Weir operations to USFWS and WDFW on March 11, 2019)*.
- Tonseth will convene a Joint Fisheries Parties meeting to discuss marking to identify hatchery x hatchery returns from fish used to backfill the Nason and Chiwawa Conservation Program.
- Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding Broodstock Collection Protocol topics for presentation in HCP-HC and PRCC HSC meetings throughout the year.

Hillman and Rohrbach will help the HCP-HCs and PRCC HSC identify co-authors and opportunities to make revisions to the Protocols in advance of 2020 deadlines Decision Summary

- There were no decisions approved during today's conference call.

Agreements

- There were no agreements discussed during today's conference call.

Review Items

- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC including the revised draft 2019 Broodstock Collection Protocols on March 8, 2019. Mike Tonseth requested that final comments on the clean copy of the revised protocols be submitted to him by March 15, 2019.

Finalized Documents

- No items have been recently finalized.

I. Welcome

A. Review Agenda (Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and said the purpose of today's call is to review the revised draft 2019 Upper Columbia River Broodstock Collection Protocols (Protocols).

Hillman asked if there were any questions regarding the approach to reviewing the Protocols. Todd Pearsons said that most of the questions or concerns raised by the PRCC HSC had been resolved in the most recent edits. Hillman said that all parties except NMFS and U.S. Fish and Wildlife Service (USFWS) have submitted comments. Bill Gale said USFWS had similar comments to those already submitted by the other parties and will add some in today's meeting as needed.

II. Joint HCP-HCs and PRCC HSC

A. Broodstock Collection Protocols Review (Mike Tonseth)

Mike Tonseth said that after presenting the first draft of the Protocols, there were two major outstanding issues to resolve: 1) trapping at the Priest Rapids Dam Off-Ladder Adult Fish Trap (the OLAFT); and 2) Wenatchee spring Chinook salmon broodstock collection. Tonseth said both have been resolved in the revised draft Protocols.

Tonseth reviewed the following outstanding issues, which were flagged for discussion and resolution. Tonseth said additional comments or edits from other parties could be addressed after discussing those he had flagged.

Appendix K: Mid-Columbia Coho Salmon, page 3

Tonseth said there is uncertainty about whether the Douglas PUD coho salmon program would receive green eggs [or eyed eggs] from coho salmon broodstock collection facilities. The comment from Greg Mackey reads,

> DPUD [Douglas PUD] would prefer to receive green eggs for our Coho program spawned at WNFH. The 2018 brood was too advanced because they were brought to Wells as eyed eggs. We need to chill the eggs to hold them back to rear the Coho at Wells – or they will get really big. Need to note this in the Appendix K when it arrives.

Tonseth said he will rely on Mackey and Keely Murdoch to decide how best to revise the coho salmon protocol. Murdoch said Douglas PUD had sent a paragraph of suggested language immediately prior to this conference call and that she will need to discuss with others not on this call to resolve the uncertainty. Murdoch said her concerns with the proposed language are the specific naming of Winthrop National Fish Hatchery (WNFH) and that it commits the YN to the use of green eggs. Murdoch said she would rather insert language allowing flexibility to use eyed eggs or green eggs. Murdoch said there is a need to discuss the choices with WNFH and YN staff to resolve the language. Mackey said it's an issue of incubation timing. Tonseth said the parties have an opportunity to submit final edits to the Protocols by end of day (EOD) on March 15, 2019.

Bill Gale said if suggested changes need to involve USFWS staff to please keep himself and Matt Cooper informed as well. Mackey said he will forward the suggested language to Gale and Cooper.

Use of Age-3 Spring Chinook Salmon Males (Jacks) into Methow River Basin Broodstock, pages 5 and 6

Tonseth said the issue of including age-3 males (jacks) in broodstock remains unresolved. Tonseth said that Mackey is not greatly supportive of using age-3 males in broodstock, but alternatively has suggested designing better (non-random) mating strategies (to select for older males) such as those proposed in Hankin et al. (2009, 2011). Tonseth said the question for the HCs is whether to carry on with the status quo this year or take on a different strategy this year. Mackey said he initially brought up the idea of using NOR age-3 males on a limited basis in place of hatchery-origin (HOR) males if age 4+ NOR males are in limited supply. Mackey said it would be wise to pursue a mating protocol that more integrates aspects of population management. Tonseth said a protocol using genetic data and age data for each fish could produce a more robust mating matrix to avoid familial crosses. Tonseth said this approach could be done with the Nason conservation program because all fish would be handled at Tumwater Dam. It could also be used for the Twisp/Methow conservation program. Tonseth asked whether representatives still want to consider this new approach in 2019. Todd Pearsons said consideration of a new approach to the mating matrices is worth discussion, but time constraints prevent making a decision this year. Pearsons suggested adding some language that allows flexibility to consider alternative strategies in the future.

Pearsons said this is one example of rushing the discussion of large topics so close to the Protocol deadline such that the representatives feel constrained about making decisions. Pearsons said he would prefer to design a process that starts these discussions earlier in the year so large changes can be made prior to drafting Protocols. Tracy Hillman said that Tonseth identified this topic last March/April (2018) and that researching the use of age-3 fish in the broodstock has been an action item for some time. Pearsons clarified that the new part being proposed is the mating matrix to avoid familial crosses, not the use of age-3 fish in the broodstock. Hillman said that he and Larissa Rohrbach will keep this and other outstanding issues on the HCP-HCs and PRCC HSC agendas throughout the year to encourage earlier discussion.

Fall Collection of Summer Steelhead Broodstock, pages 8 and 9

Tonseth said the first draft of the Protocols described eliminating the fall collection of back-up steelhead broodstock for the Methow Safety-Net (MSN) and Okanogan programs. This alternative is to backfill the MSN with 160,000 juveniles from a spring-collected component. Mackey said they could move forward with the protocol as written.

Mackey said he could summarize numbers for Committee discussion to estimate the likelihood that all broodstock could be collected at the Wells Volunteer Trap in the spring to eliminate fall-collection for the MSN and Columbia Safety-Net (CSN) programs. Tonseth said he is not opposed to moving the CSN collection to spring as well as the MSN collection. Mackey said that for the CSN program, fall collection is ok, but the spawning season is long, over 10 to 12 weeks with many egg-takes, so it is easier to take all brood in the spring to coordinate spawning. Tonseth suggested adding placeholder language to the Protocols explaining that an update can be made once average numbers of fall and spring brood are reviewed and this topic can be revisited. Tonseth said for this year, there are likely to be sufficient numbers for spring collection; however, it is unknown if there will be a sufficient number of females. Mackey said he will work with Tonseth to incorporate edits to the Protocols as soon as possible.

Trapping and Utilization of Spring Chinook Salmon in the Methow Basin, pages 7, 8, and 35

Tonseth said the Methow spring Chinook salmon forecast indicates that there will not be sufficient numbers to meet a release target of 400,000 for the safety-net program at WNFH. Tonseth suggested using any Methow Hatchery returns (HOR) for translocation out to the spawning grounds. Tonseth said this will require a plan for collection of the adults and locations for translocation. Tonseth said otherwise WNFH returns (surplus to the Methow Hatchery program) would be used for broodstock to meet the 400,000-smolt production target for WNFH program and the Chief Joseph Hatchery (CJH) 10j program. Tonseth said there will probably not be a need for adult management at the Methow Hatchery trap unless the run size exceeds forecast. Gale asked if this proposed use is for Methow Hatchery HOR fish returning to Methow Hatchery. Tonseth said yes, and Methow Hatchery returns to WNFH. Gale said USFWS has PNI targets to meet for the Methow Spring Chinook Salmon Hatchery Program Biological Opinion (BiOp) and must ensure they do not violate the BiOp by shunting all fish for translocation. Gale said that PNI targets may not be relevant with such low numbers this year. Tonseth said PNI targets are provided in Table 6, page 37, and are based on estimated WNFH, Twisp, and Methow/Chewuch returns. Tonseth said even though no adult management occurs other than removal of age-3 males, PNI would still be above 0.67. Tonseth said if all surplus fish are translocated (56 WNFH fish), PNI would drop to 0.67 but given the size of the return, the PNI could go as low as 0.5 and still meet the conditions of the permit. Gale asked if these

PNI calculations were made with the 3-population model. Tonseth said this was calculated using the more rudimentary method, but it doesn't vary much from the 3-population model.

Gale asked if there are planned translocation areas and logistics. Tonseth said there is a translocation plan that was developed by the Hatchery Committees about 3 years ago that identified locations, but there haven't been enough adults to carry through with it yet. He said this year the low numbers almost necessitate carrying out the translocation plan to maintain some minimum level of spawner abundance in the natural environment. Tonseth said he will redistribute the translocation plan this week and it can be discussed in the HCP-HC meeting next week (March 20, 2019). Gale asked, out of the 329 expected HOR spawning escapement, how many would you transport? Tonseth said up to a total of 163 spawners would be transported (excluding the 56 surplus HOR fish from WNFH) and the proportion of hatchery-origin spawners (pHOS) would range from 23% to 29%. Tonseth said if the run-size is more robust than predicted, a management decision could be made to rapidly change the approach. Peter Graf asked what the total number proposed for translocation is and where they would be collected. Tonseth said there would be 163 HOR spawners for translocation and he could ask Humling and Snow to estimate the number of Methow returns that are likely to return to WNFH. Gale said this number also depends on how the Methow trap is operated; the proposal would be to run the Methow trap to remove WNFH fish, instead of shutting down the ladder early so that WNFH fish are passed. Tonseth agreed that this proposal depends upon running the Methow trap late in the season so spawners can be collected and moved to desirable locations rather than leaving them in the creek. Gale said USFWS is likely supportive but has concerns about sending all HOR fish that arrive at WNFH away to translocation sites. Gale will review the details of the plan and discuss it with Humling before making a decision.

Appendix C: Wenatchee Spring Chinook Salmon Adult Management, page 32-33, Table 2

Tonseth said that for the Wenatchee Basin, he does not anticipate the need for any adult management (other than removal of age-3 males). Tonseth said the run forecast is low enough that fish not needed for broodstock can be allowed to escape. Pearsons said that after removing jacks the sex ratio looks low for males and asked whether it is a good idea to remove all the jacks. Tonseth said during handling at Tumwater Dam, the sex ratio has been reduced to 75% males and assuming males can spawn with more than one female, this ratio is adequate without allowing jacks. Tonseth said trapping doesn't occur at all hours of the day at Tumwater Dam, so some jacks will likely pass when the trap is not in operation. Pearsons asked if the sex ratio could be higher toward males than reflected in Table 2? Tonseth said yes, noting it is difficult to predict the number of jacks. Pearsons said this could be an effective population size issue. Tonseth said the Committees could look at the recent 5-year summary to estimate number of age-3 males that have made it past Tumwater.

Pearsons said it is desirable to get closer to a 1-to-1 ratio. Tonseth said he would not recommend allowing all males upstream, especially if there is a high jack number.

Peter Graf asked if handling of adult spring Chinook for adult management and the Relative Reproductive Success (RRS) study occurs simultaneously at Tumwater Dam. Tonseth answered, yes. Catherine Willard asked if handling adult spring Chinook for the RRS study at Tumwater would continue past 2018. Willard said that in 2014, the HCs had approved an extension of the RRS study and asked if there is an update. Tonseth said the extension was for the 2018 brood, so there is a need to track the cohort through 2023. Willard said meeting notes indicate that no passive integrated transponder (PIT)-tagging of adults would be done from 2018 to 2023. Tonseth agreed, no PIT-tagging would be done, but DNA sampling would be necessary in 2019 to 2023 to sample the 'grandchildren' (F2 generation) of the initial 2013/2014 cohort. Tonseth said the 2018 brood will be the last group DNA-sampled as juveniles and as returning adults. Tonseth said he will confirm with Andrew Murdoch that DNA sampling of the 2018 to 2023 returns is still consistent with the original agreement that was recorded in notes or in an SOA. Willard suggested updating the January 2014 memorandum on the extension of the RRS study to clarify. Willard will send the RRS study extension memorandum to Rohrbach with the translocation plan for distribution.

Twisp River Steelhead Conservation Program, page 10

Tonseth said that in Appendix H (the draft preferred alternative approach for the Methow Basin Steelhead Conservation plan), Mackey suggested committing to a 5- to 10-year plan and, if necessary, to identify what modifications are needed. Mackey said that Douglas PUD has collected broodstock with USFWS by angling in the river and at the Twisp Weir, then brood go to WNFH, where they are spawned, and eggs are dispersed into the S1 program at Wells and S2 program at Winthrop. Mackey said capturing brood by angling was a stop-gap measure to address the Raiman-Laikre issue that was raised 2 years ago, but there was a question from the YN about whether it will continue to be successful to collect broodstock by hook-and-line for the preferred alternative. Mackey said last spring was the first spring when the preferred approach was implemented; it was successful even in a low return year and produced a surplus of eggs. Mackey said that hook-and-line collection could be similarly successful this year. Murdoch said YN was skeptical whether all broodstock could be collected via hook-and-line and said it will be important to keep the effort up and reevaluate the approach if it's not working. Cooper confirmed it has been easy to find volunteers. Cooper said they are close to meeting their brood component this year. Cooper said it has helped that there hasn't been a fishery, so fish are naïve and easily captured this year despite the cold water. Gale said the challenge to this approach would be if there is a large enough run that a fishery is allowed and broodstock collection should be carried out with hook-and-line; this could be a case for allowing a fall fishery only. Tonseth added, or a fishery only after brood have been collected. Tonseth proposed moving the preferred alternative approach forward instead of maintaining it as a draft in the Protocols but adding a sunset date for re-evaluation. Gale suggested sending the Protocols to Humling and Snow for review, then making a final decision in the March 20 HCP-HC meeting.

Tonseth asked the representatives for any additional comments or questions. Gale said he had three topics to discuss further, as follows:

Use of Chief Joseph Hatchery Segregated Fish Collected in the Methow Basin

Gale said he is uncomfortable using CJH fish collected in the Methow Basin for the backup program at CJH, because it would be using identified stray fish as brood in the CJH. Gale suggested deletion of the bulleted statement at the top of page 3, adding that the action would not provide many fish for the CJH program anyway. Tonseth said this was an addition by Kirk Truscott and that Truscott did revise it to use the word “may.” Tonseth said a decision on retaining or deleting this action would be made in the next HCP-HC meeting on March 20, 2019, with Truscott in attendance.

Collection of Summer Chinook Salmon at Wells Dam for the Yakima River Program

Gale noted that the collection of summer Chinook salmon at Wells Dam seems to have been struck completely by Truscott. Gale said this makes collection at Entiat Hatchery the default, which has not been discussed. Gale said the use of surplus fish at Wells Dam should be maintained as a possibility and should be discussed with Truscott in attendance. Murdoch said Truscott would not be able to approve a protocol that reserves surplus fish from Wells Dam for the YN from the outset but noted that perhaps surplus fish could be acquired as eggs. Murdoch has informed YN staff that these conversations are ongoing. Tonseth said the YN is on the surplus fish distribution list for receiving surplus eggs, but typically decline. Truscott is suggesting that YN not decline this surplus in the future. Gale asked for the parties to keep him informed so the Entiat Hatchery is not the primary source for the YN program, which would impact USFWS’s ability to use surplus fish at Entiat Hatchery for other reasons.

Chiwawa Weir Operations

Gale said Cindy Raekes and Sierra Franks (USFWS) reviewed protocols for broodstock collection at the Chiwawa Weir and may suggest some edits. Raekes said USFWS has concerns about the cumulative trapping day limit. Raekes suggested holding to the 15-day trap limit and then adjusting to continue trapping later in the season, if needed. Raekes said some spawning data are also lacking for determining the 5-year estimated mean number of adult bull trout in the Chiwawa Basin. Raekes said all the other content in the Protocols seems consistent with the BiOp for the Wenatchee River

Spring Chinook Salmon, Summer Chinook Salmon, and Steelhead Hatchery Programs (November 2017).

Tonseth said the concern is the lack of NOR returning this year. Tonseth said bull trout are so much more abundant than spring Chinook salmon in years like this that the 15-day trapping limit is a handicap to broodstock collection. Tonseth said the Protocols list the same number of days allocated as last year (20 days) but the program still did not meet the NOR target.

Gale said USFWS is suggesting starting with 15 days of trapping, then evaluating whether more days should be added. Gale said that last year the additional days didn't help to collect additional NOR spring Chinook salmon. Tonseth said the Protocol lacks flexibility and does not want to be constrained to using the additional trapping days at the end of the season. Tonseth said that if they had allocated those additional 5 days at a different time, the flexibility could have allowed them to be used at the beginning or middle of the run. Willard noted the weir did not begin operation until later in the season due to high flows. Gale said spring Chinook salmon were missed at the beginning of the season not because days were being held in reserve but because of high flow conditions. Tonseth said he wants to avoid a situation that limits trapping days and then requires two to three weeks to resolve in season so that resolution occurs too late in the season. Gale and Raekes said they will suggest edits that would be amenable to both WDFW and USFWS and in line with the bull trout BiOp. Willard said she will look through notes and emails to confirm what happened last year.

In-Season Brood Number Adjustments

Mackey said that for programs using hatchery fish (safety-net and harvest programs, in particular), it would be helpful for all to agree to a range in the target numbers rather than a single target number.

Mackey said a range would provide some bounds for program managers to make decisions in-season and make adjustments if the fish look beat-up, smaller, or younger than expected so that fecundity and/or survival would be low. Mackey said he has a model for estimating confidence intervals to arrive at a range of target numbers instead of point estimates. Tonseth agrees to have this discussion but that to change the past practices it should be presented to the HCP-HCs and PRCC HSC as a proposal. Tonseth said there will be variability in how much latitude could be provided, especially for listed populations. Mackey agreed that listed stocks might be tightly regulated to a specific number; however, the safety-net and harvest programs often have surplus fish anyway, and this would allow some flexibility on using them for brood so as to provide a greater likelihood of meeting program targets. Tonseth said there is currently some latitude built-in to the Protocols; currently there is no latitude for changes in uses due to pre-spawn mortality related to culturing issues. Tonseth said he would not want to see any flexibility used as a crutch for bad culturing practices. Tonseth said this would need to be tailored to a program by program approach.

Mackey said he will reserve the issue of establishing ranges for broodstock collection targets for future discussions.

Update on Nason Conservation Program Size Discussions

Pearsons asked whether a decision was made about the sizing of the Nason program. Tonseth agreed in a discussion with Murdoch that it was premature to propose a reduction in the program at this time and that the parties may have different interpretations of the direction of the program at this time. Tonseth said that all information needs to be made available from the previous analysis for original sizing of the program, as well as updates to the life cycle model for updating the program size, and updated run size information. Tonseth notes that there is more work to do before the Joint Fisheries Parties (JFP) can move forward with a formal proposal to reduce the conservation programs.

Pearsons asked if there will be a combination of NOR and HOR fish in the Nason Conservation Program broodstock this year and if they will all be marked as conservation program fish. Tonseth said, yes. He said in discussions with Murdoch it was decided that tracking wild x wild fish for brood or escapement to the spawning ground will always be the priority. Tonseth said there is a footnote in Appendix B about the JFP discussing a secondary mark for identifying hatchery x hatchery fish to be used for adult removal, passage, or inclusion into hatchery programs. Murdoch said YN does not think a supplemental mark is necessary, but if it's important to other parties, she is willing to discuss it in the JFP. Tonseth said if there is no secondary mark, the program would lose ability to prioritize crosses when fish return. Willard asked if a decision will be made before marking this year? Tonseth said this decision may not be made prior to marking the Chiwawa fish but could be made for the brood to be marked one year from now. Willard said she will need some direction because there will be ~70% HOR fish for the brood year 2018 conservation program. Tonseth said the default mark will be a snout coded wire tag and no adipose clip.

Brett Farman said he has not had time to update his analysis of PNI using the 3-population model (to determine the influence of hatchery x hatchery spawners). Murdoch said as permits are written, it doesn't make a difference who the parents were, but it would be nice to know for the implementation of the program. Tonseth said the biggest impact to PNI when these fish return are how many we allow on the spawning grounds, which depends on the number of NOR fish. Lower NOR results in higher pHOS and higher PNI. Tonseth said the permit condition is to calculate PNI on a rolling 5-year average such that 1 or 2 bad years could be counterbalanced by good years. Tonseth will convene a JFP meeting soon to discuss this topic.

Broodstock Collection Protocols Document Production

Hillman asked why the Protocols are authored by WDFW and not by the permit holders. Tonseth said WDFW is co-permittee and there was a clause that WDFW would develop them. Murdoch said this came from the history of WDFW operating all of the hatchery programs. Pearsons said some of their (Grant PUD) permits say the permit holders should develop the annual spawning protocols. Willard said permit holders would be WDFW and the PUDs. Tonseth said that in a way, all parties do write the Protocols together during the editorial process. Tonseth said there are a number of elements that are becoming streamlined, such as materials in the appendices, allowing them to be made available earlier. Tonseth said Pearsons' comment on timelines for developing the Protocols should be addressed in the Committees and potentially lead to revising the SOA on Protocol development timelines. Tonseth said the parties would have to develop a list of which elements could be developed earlier versus later in the year.

Deanne Pavlik-Kunkel said this process feels a bit broken; there did not seem to be enough time to discuss major proposed changes to programs for the Protocols. Pavlik-Kunkel said Grant PUD's position is that there should be modifications to this process. Hillman suggested drafting parts of the Protocols in November or December of the previous year and perhaps sharing the drafting responsibility with the PUDs. Hillman said he and Rohrbach can help identify some of the big changes that require discussion prior to first draft of Protocol development and identify sections that can be worked on by others in the Committees to share the workload. Pearsons agreed that the reasonable starting point would be modifying that SOA. Pearsons said Tonseth has done everything consistent with the SOA; perhaps the Committees just need to back up the due dates. Tonseth agreed that modifying the SOA is a good place to start because the SOA is already on the books; however, it may not be an SOA for the HSC. Tonseth agreed to identifying certain pieces that can be worked on earlier.

III.PRCC HSC

A. Broodstock Collection Protocols for PRCC HSC Programs

Discussion topics pertaining to the PRCC HSC were addressed in the Joint HCP-HCs and PRCC HSC section of the agenda.

IV. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings will be held on March 20, 2019 (Grant PUD), April 17, 2019 (Grant PUD), and May 15, 2019 (Grant PUD).

Tonseth requests that comments on the revised draft 2019 Protocols be submitted to him by EOD Friday, March 3, 2019, so he can distribute a final draft back out to the representatives by EOD Monday March 6, 2019 (depending on scope of the comments).

The HCP-HCs and PRCC HSC will approve the 2019 Broodstock Collection Protocols during the March 20, 2019 meeting.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: April 18, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the March 20, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCP) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, March 20, 2019, from 9:00 a.m. to 3:30 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Tracy Hillman will review aspects of the Independent Scientific Advisory Board's *Review of Spring Chinook Salmon in the Upper Columbia River* under HCP-HCs' purview (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Fish Hatchery (FH) (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing)*
- Catherine Willard will update the genetics section of the *Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan)* based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow FH programs (Item I-A). *(Note: this item is ongoing.)*

- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating the proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs. *(Note: this item is ongoing.)*
- Brett Farman will inform the HCP-HCs of the publication date for public review of the Methow River Steelhead Environmental Assessment (Item II-F). *(Note: this item is ongoing.)*
- Brett Farman will inform the HCP-HCs on the publication date for public review of the Section 10 permits for the unlisted Chinook salmon bundle (Item II-F). *(Note: Larissa Rohrbach distributed an email from Farman and draft permits for the Section 10 programs to the HCP-HCs and PRCC HSC on March 28, 2019. This item is complete.)*
- Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service [USFWS]) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to Winthrop National Fish Hatchery (WNFH) to inform a translocation discussion during the April 17, 2019 HCP-HCs meeting. (Item I-A) *(Note: this item is ongoing.)*
- Mike Tonseth will revise and redistribute the *2017 Out-planting Surplus Methow Composite Spring Chinook Salmon Adults* memorandum for review and discussion during the April 17, 2019 HCP-HCs meeting. (Item II-A)
- Mike Tonseth will confirm with Andrew Murdoch that Wenatchee Spring Chinook DNA sampling of the 2018 to 2023 returns is still consistent with the original Relative Reproductive Success (RSS) Study extension agreement and provide an update to that extension. (Item I-A) *(Note: this item is ongoing.)*
- Mike Tonseth will convene a Joint Fisheries Parties meeting to discuss marking to identify hatchery x hatchery returns from fish used to backfill the Nason and Chiwawa conservation programs. (Item I-A) *(Note: this item is ongoing.)*
- Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A). *(Note: this item is ongoing.)*
- Tracy Hillman and Larissa Rohrbach will maintain the following list of outstanding topics for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols (Protocols). (Item I-A) *(Note: this item is ongoing.)*
  - Use of age-3 males in broodstock
  - Use of alternative, non-random mating strategies
  - Establishing ranges around broodstock collection targets
  - Source for Chiwawa spring Chinook salmon broodstock
- Tracy Hillman and Larissa Rohrbach will help the HCP-HCs and PRCC HSC identify co-authors and opportunities to make revisions to the Protocols in advance of 2020 deadlines (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will send suggested language on broodstock protocols for the Douglas PUD coho salmon program to Keely Murdoch and Cory Kamphaus (Yakama Nation [YN]) for

approval and to Mike Tonseth for inclusion into the 2019 Protocols by end of day March 20, 2019 (Item II-A). *(Note: language was incorporated into the 2019 Protocols that were distributed by Larissa Rohrbach on March 21, 2019.)*

- Mike Tonseth will email a final draft of the 2019 Protocols to Larissa Rohrbach for distribution to the HCP-HCs and PRCC HSC by end of day March 21, 2019 (Item II-A) *(Note: the 2019 Protocols were distributed by Rohrbach via email on March 21, 2019.)*
- HCP-HCs and PRCC HSC representatives or alternates will vote by email whether to approve the 2019 Protocols by end of day March 22, 2019 (Item II-A). *(Note: the 2019 Protocols were approved by the Wells, Rock Island, and Rocky Reach HCs and the PRCC HSC Parties by email on March 22, 2019.)*

Wells HCP Hatchery Committee

- Greg Mackey will provide a revised version of Douglas PUD's draft 2019 M&E Implementation Plan for HCP-HC approval by email (Item I-A). (*Note: This item is ongoing*)

RI and RR HCP Hatchery Committee

- Mike Tonseth will email the Hatchery and Genetic Management Plans (HGMPs), biological opinions (BiOps), and permits that give direction on marking spring Chinook salmon in the Chiwawa and Nason conservation and safety-net programs to Larissa Rohrbach for distribution to the HCP-HCs and PRCC HSC and filing on the Extranet site (Item IV-A). (*Note: Relevant documents were distributed and filed by Rohrbach on March 21, 2019*).
- Mike Tonseth will confirm the timeline for tagging juvenile Chiwawa spring Chinook salmon in 2019 (Item IV-A).
- Brett Farman will ask Amilee Wilson and Craig Busack (National Marine Fisheries Service [NMFS]) to clarify the intent of the direction provided in NMFS BiOps for marking Chiwawa and Nason conservation program juvenile spring Chinook salmon (Item IV-A)

PRCC Hatchery Subcommittee

- Tracy Hillman will ask the PRCC to provide specific instructions in writing regarding what they want the PRCC HSC to do with the White River spring Chinook salmon hatchery memorandum (Item V-C). *(Note: Hillman sent an email to the PRCC Chair regarding this topic.)*
- PRCC HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item V-C).

Decision Summary

- The Wells, Rocky Reach, and Rock Island HCP-HCs and PRCC HSC approved the 2019 Broodstock Collection Protocols as follows: WDFW approved via email on March 21, 2019, and Chelan PUD, Douglas PUD, Grant PUD, YN, CCT, USFWS, and NMFS approved via email on March 22, 2019. (Note: the Wells HCP-CC also approved the 2019 Protocols on March 26, 2019, and the final version was distributed to the committees on March 28, 2019.)

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- Larissa Rohrbach sent an email to the PRCC HSC on February 21, 2019, notifying them that the draft Priest Rapids Hatchery M&E Implementation Plan is available for 30-day review with comments and edits due to Todd Pearsons by March 25, 2019 (Item V-A).
- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on February 7, 2019, notifying them that the updated meeting protocols, distribution lists, and draft Conflict of Interest Statement of Agreement (SOA) are available for review (Item II-B).
- Larissa Rohrbach sent emails to the HCP-HCs and PRCC HSC on March 28, 2019, notifying them that the draft NMFS Section 10 Permits for the Takes of Endangered and Threatened Species are available for review with comments due to Emi Kondo (NMFS) by April 15, 2019.

Finalized Documents

- Larissa Rohrbach distributed the final 2019 Wells HCP Action Plan, approved by the Wells HCP-Coordinating Committee, to the HCP-HCs on March 22, 2019.
- Larissa Rohrbach distributed the final 2019 Protocols, approved by the HCP-HCs, to the Wells Coordinating Committee Chair and copied the PRCC facilitator, on March 22, 2019, for approval by the Wells HCP-CC (Item II-A).
- Larissa Rohrbach distributed the final Wells HCP Annual Report, approved by the Wells HCP-Coordinating Committee, to the HCP-HCs on March 28, 2019.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and approve the February 20, 2019 Meeting Minutes (Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and asked for any additions or changes to the agenda. Catherine Willard added the topic "Marking brood year 2018 Chiwawa spring Chinook salmon" to the Rock Island Hatchery Committee section of the agenda. The HCP-HCs and PRCC HSC representatives approved the revised agenda.

The HCP-HCs and PRCC HSC representatives reviewed the revised draft February 20, 2019 meeting minutes. Larissa Rohrbach said there were some revisions that the representatives then reviewed. The HCP-HCs and PRCC HSC representatives approved the draft February 20, 2019 meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on February 20, 2019, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on February 20, 2019 and March 11, 2019)*:

Joint HCP-HCs and PRCC HSC Topics

- *Tracy Hillman will review aspects of the Independent Scientific Advisory Board's* Review of Spring Chinook Salmon in the Upper Columbia River *under HCP-HCs' purview (Item I-A).* Hillman said this item is ongoing. He said protocols will be updated as tools are developed for the 10-year comprehensive reports.
- *Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery; Item I-A).* Mackey said this item is ongoing.
- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) regarding presenting pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HCs meeting (Item I-A).*
  Tonseth said this item is ongoing, pending acquisition of additional information to inform the model.
- *Catherine Willard will update the genetics section of the* Monitoring and Evaluation Plan for PUD Hatchery Programs (2017 Update) *based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A).*
  Willard said this item is ongoing.
- *Greg Mackey will confirm with Betsy Bamberger (Douglas PUD) whether Douglas PUD will use the Washington Animal Disease Diagnostic Laboratory (WADDL) for in-season bacterial kidney*

disease (BKD) testing during 2019 broodstock collection and confirm that WADDL methods will provide ELISA [enzyme-linked immunosorbent assay] optical density test results (Item I-A).
Bamberger said this item will be discussed in today's meeting.

- *Kirk Truscott will discuss with Colville Confederated Tribe (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A).*
  Truscott said this item is ongoing.
- *Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A).*
  Rohrbach said this item is ongoing.
- *Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating the proportionate natural influence (PNI) for the Nason spring Chinook and Chiwawa spring Chinook programs (Item II-A).*
  Farman said this item is ongoing.
- *Brett Farman will inform the HCP-HCs of the publication date for public review of the Methow River Steelhead Environmental Assessment (EA) (Item II-F).*
  Farman said this item is ongoing and it was further discussed in section II-F.
- *Brett Farman will inform the HCP-HCs of the publication date for public review of the Section 10 permit for the unlisted Chinook salmon bundle (Item II-F). (Note: Farman emailed Larissa Rohrbach on March 6, 2019 to inform the Committees that the UCR unlisted Chinook NEPA and HGMP bundle will be published within the week.)*
  Farman said this item is ongoing and it was further discussed in section II-F.

Joint HCP-HCs and PRCC HSC Topics for Finalizing the 2019 Upper Columbia River Broodstock Collection Protocols

- *Greg Mackey will forward Douglas PUD's suggested revisions describing broodstock and egg obtainment for the Douglas PUD Coho program (refers to Appendix K of the Protocols) to Keely Murdoch, Bill Gale and Matt Cooper for their review before inclusion in the Broodstock Protocols.*
- *(Item II-A).*
  Mackey said this item is complete.
- *Mike Tonseth will add language to the Protocols that allows flexibility in the future to select for older males using alternative, non-random mating strategies (Item II-A).*
  Tonseth said language has been added allowing flexibility for inclusion of age-3 males. Mackey said proposals to change mating strategies should be discussed in future meetings with more thoughtful research, but timing was not adequate for the 2019 Protocols.

- *Mackey will summarize numbers for Committee discussion and make edits to Protocols on the likelihood that all summer steelhead broodstock could be collected at the Wells Volunteer Trap in the spring to eliminate fall-collection for the MSN and Columbia Safety-Net (CSN) programs (Item II-A).*

  Mackey said he will discuss this item during today's meeting.
- *Tonseth will redistribute the Methow Basin spring Chinook translocation plan for review and discussion in the March 20, 2019 meeting. Tonseth will ask Michael Humling (USFWS) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to WNFH (Item II-A).*

  Tonseth said this item is ongoing (with Humling and Snow).
- *Catherine Willard will send the Relative Reproductive Success (RRS) study extension memorandum to Rohrbach with the translocation plan for distribution (Item II-A) (Note: Rohrbach distributed an email from Willard and the attached RRS study extension and translocation plan to the HCP-HC and PRCC HSC following the March 11, 2019 conference call).*

  Willard said this item is complete.
- *Tonseth will confirm with Andrew Murdoch (WDFW) that DNA sampling of the 2018 to 2023 returns is still consistent with the original RRS extension agreement and provide an updated extension (Item II-A).*

  Tonseth said this item is ongoing.
- *Tonseth will send the Methow Basin Steelhead Conservation program preferred draft alternative for collecting broodstock by angling to Humling and Snow for review (Item II-A).*

  Tonseth said this item is complete.
- *Bill Gale and Cindy Raekes (USFWS) will send suggested edits to Mike Tonseth regarding the Chiwawa Weir operations protocols to optimize operation and protect bull trout per the BiOps (Item II-A).*

  Gale said this item is complete.
- *Willard will email notes that summarize 2018 Chiwawa Weir operations (Item II-A). (Willard notified Rohrbach that she emailed details on 2018 Chiwawa Weir operations to USFWS and WDFW on March 11, 2019).*

  Willard said this item is complete
- *Tonseth will convene a Joint Fisheries Parties meeting to discuss marking to identify hatchery x hatchery returns from fish used to backfill the Nason and Chiwawa Conservation Program (Item II-A).*

  Tonseth said this item is ongoing.
- *Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding Broodstock Collection Protocol topics for presentation in HCP-HC and PRCC HSC meetings throughout the year (Item II-A).*

Hillman said this item is ongoing

- *Hillman and Rohrbach will support the HCP-HC and PRCC HSC to identify sections of the Protocols that can be authored earlier in the drafting process by various HCP-HC and PRCC HSC members in future years (Item II-A).*
  Hillman said this item is ongoing; potential approaches to be determined with HCP-HCs and PRCC HSC members' help.

Wells Hatchery Committee

- *Greg Mackey will provide a revised version of Douglas PUD's draft 2019 Monitoring and Evaluation (M&E) Implementation Plan for HCP-HCs approval by email (Item I-A).*
  Mackey said this item is ongoing.

II. Joint HCP-HCs and PRCC HSC

A. Approve Broodstock Collection Protocols for HCP-HC Programs – DECISION ITEM

Mike Tonseth said there is an additional version of the Protocols that reflects edits provided by USFWS late on March 19, 2019. Tracy Hillman projected the most recent version during the meeting for review.

Tonseth said the following three topics lack resolution in the Protocols:

1. Elimination of back-up steelhead collection in the fall at the Wells Volunteer Channel
2. Chiwawa Weir spring Chinook salmon trapping plan that minimizes impacts to bull trout in compliance with USFWS permits
3. Translocation of surplus adult Methow spring Chinook salmon

Backup Steelhead Collection in the Fall at the Wells Volunteer Channel

Tonseth said the HCP-HCs representatives agreed to the proposed elimination of all back-up collection of Methow and Okanagan steelhead broodstock in the fall.

However, Tonseth said there was not resolution on whether to continue to collect fall backup broodstock for the Columbia Safety Net steelhead program from the Wells Volunteer Channel. Tonseth said the concern, particularly this year when the run is low, is there may not be enough females collected in spring when the majority of fish moving through the rivers are more likely to be males.

Greg Mackey provided a summary of the number of fish in the CSN program. Mackey said the CSN releases 160,000 smolts directly into the Columbia River. He said adult return counts are only available for very recent years because the program is relatively new in its current form and fish have not been surplused from the Wells FH Volunteer Channel until recent years. Mackey said that in

2017, there were 224 and in 2018 there were 242 adult steelhead returns to the Wells FH Volunteer Channel. Mackey did not know the sex ratios. Mackey said these represent swim-ins in approximately March, but more could be collected with increased effort. Mackey said for the CSN, 86 steelhead would be needed, so there are plenty of spring returns to cover the CSN.

Mackey said that between captures by angling (USFWS) and captures at WNFH that could be used for the CSN (or MSN) program, there are currently 44 fish (21 males and 18 females). Mackey estimated that today potentially a couple hundred fish would be cleared out of the Wells Volunteer Channel, enough to cover the approximately 40 remaining needed for the CSN. Bill Gale said WNFH just started trapping in the weir and volunteer channel last week and may capture fish from other programs. If there is a surplus (in excess of needs for WNFH brood and the Methow Safety-Net program), those fish could be used for the CSN. Mackey asked if there are other intended uses for surplus fish at WNFH. Gale said that in the past there were other uses (e.g., spawning trials) but this year there are none. Gale asked if CSN spawning happens at Wells Hatchery. Mackey said yes. Gale said one difficulty of putting WNFH fish into the CSN program would be the transfer to Wells because spawning is happening now at WNFH. Kirk Truscott said if the Protocols are edited, he would want to make sure Methow program targets are met before allocating surplus fish from Methow FH to the CSN. Truscott also requested that if the Committee agrees to no back-up collections in the fall, that the volunteer ladder collection to back-fill shortfalls in the Okanogan Program will be prioritized above the CSN program. Tonseth said it may be a good test to operate the (Wells) Volunteer Trap this spring as if doing adult management to see how many adults there are and what the sex composition is to anticipate what to expect for the 2020 brood.

Mackey said a good estimate of the total run is possible as adults come up the Columbia River in the fall. It could be assumed that only spring collection would be done unless the run forecast looks bad, then additional fish could be captured in September or October.

Tonseth said a concern is the 2019 return is predicted to be low for 1-salt steelhead to be used for the 2020 brood. Truscott said this could result in a skewed sex ratio toward females.

Mackey said maintaining fish health while holding fall-collected fish on well-water for extended periods of time is also a challenge.

Mackey said, for program flexibility, an in-season decision could be brought to the HCs based on run size; if the run is low, fish could be collected in the fall. Mackey said this could be a formal decision or a notice to the HCs. Gale said USFWS would like this to be a formal decision by the HCs rather than a notice. Gale asked if the in-season decision would only pertain to using surplus brood for the CSN. Mackey answered yes.

Hillman asked if the edits to the Protocols are adequate. Mackey said the protocol was edited to move entirely to spring collection of steelhead broodstock. Tonseth said if all are comfortable with this change, he will accept those edits. Truscott said CCT gives provisional approval based on adequate numbers to meet Methow program targets. Tonseth will revise the Protocols to reflect the suspension of fall collection of steelhead brood for the CSN with flexibility for the HCs to make an in-season decisions if the fall run-size looks low.

Chiwawa Weir Operation

Tonseth said USFWS provided language that dictates the parties (i.e., WDFW and Chelan PUD) that would give notice to the USFWS if there is a need to change the number of days of Chiwawa Weir operation causing a change in the numbers of bull trout encountered. Gale said this would require informing USFWS Ecological Services. Cindy Raekes (USFWS) has approved this language. Truscott asked whether 20 days of trapping at the Chiwawa Weir has already been authorized. Gale and Tonseth answered yes. Gale said the allowance is to encounter less than 10% of the estimated bull trout spawning population. Last year this allowed for a limit of 93 encounters at the weir. Gale said the intention of the language in the Protocols is for USFWS Ecological Services to review the Protocols each year.

Tonseth said due to low expected run size, any natural-origin spring Chinook salmon encountered during the Chiwawa Weir collection days will be retained.

Out-Planting Methow Spring Chinook (Appendix C)

Gale said he provided comments on the Protocols regarding how Methow FH natural-origin spring Chinook salmon are retained for Methow FH broodstock. Gale reminded the Committees members that translocation of all Methow FH returns not needed for broodstock to natural spawning areas was proposed by WDFW. Gale said that: 1) USFWS thinks active trapping at Methow FH should be done to prevent hatchery fish from spawning at the hatchery outfalls; and 2) USFWS is concerned about out-year effects on PNI of using only WNFH fish for brood. Gale said that according to the 3-population PNI prediction, it will be harder to meet the PNI goal of 0.67. Gale said USFWS suggests an approach of prioritizing females for out-planting and using males for WNFH brood. This approach keeps PNI at 0.5, minimizes hatchery by hatchery spawning in the wild, and promotes female-driven hatchery by wild spawning in the wild. Gale said the intent would be to use the translocation plan that was developed 2 years ago as a starting point (2017; distributed by Larissa Rohrbach on March 11, 2019).

Tonseth said there are three proposals to consider:

1. The original proposal to allocate all Methow FH returns (to Methow FH and WNFH) in excess of needs for WNFH for translocation
2. Maintain males for use at WNFH for broodstock
3. Allocate all Methow FH adults that return to Methow FH for translocation, and allocate all females that return to WNFH for translocation

Tonseth said the proposals would require operation of traps at Methow FH and WNFH for the full season to collect brood and collect Methow FH fish to translocate them to desirable sites (instead of spawning at the hatchery). Any translocation would depend upon return rates. Gale said a certain percentage of returning adults will bypass trapping even if traps are run; estimating this escapement would be a useful detail. Mackey asked whether in the original translocation plan there was a cap on the number to be translocated. Gale said yes, a cap of 200 hatchery-origin spring Chinook salmon adults was proposed; with a sex ratio that was skewed toward females (F:M of 1.0:0.2). Tonseth said based on the current run prediction, he has concerns there will be few males and translocation of too many females would bias interpretation of the success of the program if those females cannot find mates in the wild. Truscott said the Protocols should be clear that translocation is an issue that depends upon adequate returns. Truscott said allocating fish for translocation could cause a trickledown effect resulting in a lack of sufficient Methow FH returns for broodstock to support the Winthrop NFH stepping-stone production, requiring Winthrop returns to be used to satisfy Winthrop production and potentially jeopardizing Okanogan 10j broodstock collection that utilize Winthrop returning adults.

Tonseth said the Protocols will state that the 2017 translocation plan will be revisited and recommendations will be made for the 2019 activities.

Douglas PUD Program Comments and Revisions

Mackey said he revised a paragraph to be inserted into the YN coho salmon program appendix reflecting that Douglas PUD has a coho salmon program with broodstock collected within the YN program. The language also describes the activities based on discussions with Keely Murdoch and Cory Kamphaus. Mackey will send language to Tonseth and Keely Murdoch for her approval and inclusion into the Protocols by the end of today.

Mackey said Douglas PUD hatchery staff desire higher brood numbers than described in the Wells summer Chinook salmon yearling and subyearling broodstock collection plans. Mackey said Douglas PUD will not hold up approval of the Protocols but changes for these programs could be made between now and July 1. Tonseth said if it makes sense to change the plan, it is supported by WDFW.

Tonseth will send final revised Protocols to the HCP-HC and PRCC HSC representatives by late Thursday for email vote on Friday so the Protocols can be presented to the Wells HCP Coordinating Committee next week. Rohrbach will email final Protocols to the Wells HCP Coordinating Committee Chair (John Ferguson) and support (Kristi Geris) by the end of the day Friday.

B. Streamlining

Tracy Hillman said this topic will be addressed in a future meeting.

C. Spring Chinook Salmon Carcass Recovery Bias

Andrew Murdoch said there are two papers that describe approaches to estimating spawning escapement using carcass recovery methodologies (distributed to the Committees by Larissa Rohrbach on March 19, 2019[1,2]). Andrew Murdoch said the model is being refined to be submitted for publication this fall.

Andrew Murdoch said Mike Hughes (WDFW) will give a presentation, then Andrew Murdoch will provide an overview of carcass recovery methodologies that can be used. He will describe three variations for spring Chinook salmon and three for steelhead at a high level of detail.

Hughes gave a presentation entitled “Spring Chinook Carcass Recovery Bias in the Upper Wenatchee Basin.” This is preliminary work developed by Hughes and Kevin See (Biomark). The key messages from the presentation are noted here.

- Slide 2: There are biases in carcass recovery on the spawning grounds resulting in biased spawning population estimates.
- Slide 3: Study objectives are to develop a model that predicts spring Chinook salmon carcass recovery rates in the upper Wenatchee Basin and corrects for biases. Results were shown for 2011 and 2013.
- Slide 4: Methods. 100% of fish were marked at Tumwater Dam. Tagging was done in June and July and carcasses were recovered in September. Pre-spawn mortalities and fallbacks presented problems. To address these problems, only detections of live passive integrated transponder (PIT)-tag fish on spawning grounds were used as recovery data.
- Slides 5 to 8: Recovery rates are highly variable between years. Other factors affecting recovery include river discharge (high water years vs low water years) and stream type (glacial-fed streams having lower recovery due to turbidity than non-glacial streams).

---

[2] Murdoch, A.R., C.J. Herring, C.H. Frady, K. See, and C.E. Jordan, 2018. Estimating observer error and steelhead redd abundance using a modified Gaussian area-under-the-curve framework. Can. J. Fish. Aquat. Sci. 75: 2149–2158 (2018) dx.doi.org/10.1139/cjfas-2017-0335

- Slide 9: Recovery rates also vary by channel type (pool-riffle vs plane-bed) with less complex channel types (plane-bed channels) showing a trend toward lower recovery rates.
- Slides 10 and 11: Across all 10 years of data, median recovery rate by sex shows recovery of females is greater than males. This reflects post-spawning behavior of females as they guard redds and die near the redd. In contrast, males are not faithful to specific spawning locations and can be found in the thalweg or pools. There is also a trend toward recovery of larger fish of both sexes.
- Slide 12: Recovery variability was examined using the following variables in the model: river discharge, stream type, channel type, sex, and fish size. Fish origin was not added into the model because no differences were observed between natural-origin and hatchery-origin fish. Differences in size and behavior are captured in the other variables.
- Slides 13 to 16: Relative importance of variables were shown graphically. The following conclusions were made:
  - Lower recovery was experienced with higher discharge, glacial streams, and plane-bed channel types for both males and females.
  - Size (post-orbital to hypural length [POH]) has almost no influence on recovery of female carcasses. They observed interactions between stream type and discharge. Freshet information was not included in the model for females.
  - Size and freshets affect recovery of male carcasses.
- Slides 17 and 18: At this time, they have examined corrected versus non-corrected data for only 2011 and 2013. Survey programs are underestimating the number of younger males.
  - Todd Pearsons asked why 2011 and 2013 were chosen for analysis. Hughes said 2011 was a high jack and high discharge year, while 2013 was a more average water year and typical Tumwater return (jack return). Andrew Murdoch said all years will be analyzed; these are preliminary results and they are unsure how representative these years are.
- Slide 19: Fish per redd and spawning abundance. Comparison shown between estimates for observations at Tumwater Dam, observed carcasses, and corrected by channel type. They also showed differences in spawning distribution between natural-origin and hatchery-origin fish.
  - Peter Graf asked what the difference is between plane bed use in 2011 and 2013? Hughes said there were many differences between years including flows and a large jack return in 2011. Andrew Murdoch said in 2013, ratios between plane-bed and pool-riffle use tended to be more similar. Hatchery-origin fish tend to use plane-bed channels because this is the channel type in the Chiwawa River near the acclimation site.
- Slides 20 to 26: Corrected sex ratios are really driven by the fish-per-redd calculation. Modeled results show that surveys would underestimate younger age-class fish and overestimate older age-class fish. Underestimation of younger fish, which tend to be HORs, causes underestimation of HORs on the spawning grounds.

Andrew Murdoch said this model shows the "spawner to carcass" phase rather than the "pre-spawn to carcass" phase, which was published in 2010 and was affected by pre-spawn mortality.

Kirk Truscott said he thought surveys were more likely to overestimate females. Hughes said the data shown are proportions, so the correction is not to add more females. Hughes said the model results are driven by the fish-per-redd ratio. By applying different fish-per-redd ratios corrected by channel type, the ratio of M:F changes. In the plane-bed reaches, the overall carcass recovery is low, compounded by more hatchery fish in plane-bed reaches.

Greg Mackey asked if it is possible the model would provide an estimate that is actually less than the actual number of carcasses observed? Hughes said no, proportions are corrected by adjusting probabilities of recovery and applying new recovery probabilities to ratios of males to female.

Andrew Murdoch said the model presented allows for the use of carcass sampling to generate fish-per-redd calculations for each channel type and each stream for more accurate estimates of spawner distribution between HORs and natural-origin returns (NOR). Andrew Murdoch said it also allows for understanding differences in space upstream from Tumwater. Mike Tonseth asked whether estimates still depend upon having robust carcass data. Hughes and Andrew Murdoch said yes, a total lack of collection of a given fish type gives outlier-adjusted results. Andrew Murdoch said rolling the data up to the evolutionarily significant unit level somewhat mitigates the influence of outliers.

Estimating Pre-Spawn Survival

Andrew Murdoch presented slide 27 on pre-spawn survival in the Chiwawa River. Andrew Murdoch said the survival estimates start with detections at the in-basin array. He said in a previous exercise, they saw HORs always had lower pre-spawn survival, but data were not corrected for carcass-recovery bias. He said corrected data show that there is a carcass bias for females driven by a lack of pool-riffle reaches in the Chiwawa River where males would be found. He said a different picture emerges when data are corrected for carcass-recovery bias. Corrected data show similar HOR and NOR pre-spawn survival rates. Andrew Murdoch said survival of males is lower for HOR fish. Results were unexpectedly different from previous analysis.

Tracy Hillman asked whether estimates in the Chiwawa River were driven primarily by most hatchery-origin fish using plane-bed reaches and the fact that hatchery-origin fish are smaller and younger? Andrew Murdoch said yes, the strongest factor is channel type and a weaker effect was fish size. He said in the past, pre-spawn survival estimates were not possible for males.

Hillman highlighted the important point that pre-spawn loss is about 40% to 70%. Andrew Murdoch said yes, the same results were observed in 2010. Andrew Murdoch said the power of the model is the number of detections observed on redds (3,500). He said they designed the model to be transferrable as long as there is information on redds and channel type.

Truscott asked whether this represents the maximum pre-spawn survival? Andrew Murdoch said yes, because measuring started near the mouth of the Chiwawa River. Thus, it does not include losses in the Wenatchee River. Mackey asked if the conclusions depend on redd counts, could one underestimate redds and underestimate survival. Andrew Murdoch said Area Under the Curve (AUC) was used to estimate spring Chinook salmon escapement and assumed one redd per female and that males spawn with one female. He said they know from the RRS study that this may not be the case. He said it is difficult to tease apart fish that returned from those that actually spawned. He said estimates of males could be high because we know males spawn with more than one female (more than one redd).

Hillman said it is surprising that survival did not change more with flows. Andrew Murdoch said yes, there is a bigger problem than anticipated to determine the factors that affect survival; this at least provides more accurate survival numbers.

Graf asked how will results be affected for 2014 and later when adult management was implemented (all jacks removed)? Andrew Murdoch said this will recast all the escapement predictions.

Keely Murdoch asked, given what you know about different habitat uses between HOR and NOR, how does this change interpretation of pre-spawn survival trends? Andrew Murdoch said the different pre-spawn survival previously observed between HOR and NOR was an effect of bias. Now the focus should be on identifying factors for pre-spawn mortality and keeping adults alive that have returned.

Graf asked whether the carcasses observed were spawned out. Tonseth said yes. Graf asked whether evidence has been found of fish that have died before spawning? Andrew Murdoch said yes, we do see them, but that finding carcasses that are not spawned out is fairly rare. He further indicated they are only looking during the spawning season and pre-spawn mortality is probably occurring throughout the season (prior to spawning). He said the females observed are those that have been guarding redds. He added there is still uncertainty about how behavior affects observation of pre-spawn mortalities.

Comparison of Methods for Estimating Spawning Escapement

Andrew Murdoch compared three methods for estimating spawning escapement for spring Chinook salmon (slides 29 and 30) and steelhead (slides 31 through 33)

The spring Chinook salmon 3.0 method is the least biased method so far; it incorporates the bias correction model, which corrects for observer bias, carcass location, and sex ratios.

The steelhead 3.0 method uses AUC but is a PIT-tag detection and redd count hybrid. This method relies on PIT tagging at Priest Rapids Dam (the off-ladder adult fish trap [OLAFT]). Andrew Murdoch said fish are not assigned to a tributary during tagging; adjustment for pre-spawn mortality is based on radio telemetry results to generate HOR/NOR and sex ratios for the mainstem. The data can be used to roll up to a population level estimate. Andrew Murdoch compared methods for different tributaries.

Entiat steelhead that survive to the mouth of the river tend to survive to spawn. In the Methow and Wenatchee basins, version 2.0 or 3.0 can be used. The Okanogan River is a very different system than where the Gaussian AUC model was developed. Truscott said there are different water conditions with high turbidity in the Okanogan and surveys are affected by stream flows, which can delay surveys for several days or weeks. Andrew Murdoch said there are models to correct for that, but it helps to capture the peak of spawning. Hillman said he thinks there is a lot of overlap between summer Chinook salmon and steelhead spawning habitat use because of a lack of suitable spawning gravels in the Okanogan River.

Pearsons said the Committees are currently in the process of analyzing data for the comprehensive report to compare supplemented (treatment) areas to references areas. He said they are lacking comparable information (unbiased data) from reference areas and asked whether they could (erroneously) be making corrections to treatment data and not reference area data, or the "after" period and not the "before" period? He said they could be making assumptions based on incorrect comparisons.

Andrew Murdoch said older data (before data) are wild fish and therefore are less biased. Programs would need to identify the bias associated with hatchery fish in the after period. He said in some cases it may be easier to adjust for observer bias with GPS data during the "after" period. Pearsons said productivity depends on both NOR and HOR data. Andrew Murdoch said if a bias is specifically associated with the treatment (e.g., supplementation with hatchery fish), that bias could be adjusted to achieve a better estimate for the treatment. He said the entire time series for the Wenatchee could be compared to other areas with less complete datasets as analysis progresses (e.g., little Wenatchee, White River).

Betsy Bamberger asked whether the old and new models could be run simultaneously? Andrew Murdoch said they will be running the old method and new method for comparison. Hillman said assuming all data are collected the same way, you can make the comparisons because the bias is likely the same for both treatment and reference areas. If you adjust one group for bias and not the other, comparisons would be confounded. Hillman said surveys in the upper Columbia River are more robust than in other regions. He said there is so much variation in the data, treatment effects are difficult to identify, and analyses lack suitable power even if there is a long time series of data.

Hillman thanked the presenters and concluded the discussion on carcass recovery bias and estimating escapement.

D. Steelhead PIT-Tagging at the Off-Ladder Adult Fish Trap and Array Operations and Maintenance

Andrew Murdoch said WDFW is still planning to move forward on PIT-tagging spring Chinook salmon at the OLAFT. Andrew Murdoch said WDFW is reducing their scope for antenna operations and maintenance but adamant about using every array necessary. They will eliminate upper Entiat Basin former Integrated Status and Effectiveness Monitoring Program (ISEMP) arrays. Andrew Murdoch said it is the goal of the Bonneville Power Administration to move operations and maintenance for all arrays (remnants of ISEMP arrays and WDFW-operated arrays) into a single project for efficiency of operations. This month PTAGIS will create an instream PIT-tag array subcommittee, which will ensure instream arrays are functioning and performing similar to mainstem arrays.

Andrew Murdoch said that use of paired antenna rows overestimates detection probability and underestimates escapement because detections by each antenna are not independent.
Andrew Murdoch said that they are advocating for detections at two sites farther apart to lower the detection bias at the lower detection point. He said they wish to demonstrate that loss of a detection point could lead to underestimation of escapement. Catherine Willard asked how far apart arrays need to be. Andrew Murdoch said arrays used are at least 10 miles apart. He said it helps for viable salmonid population metrics to have arrays at the downstream end and one in tributaries upstream. He said array placement is consistent for much of the upper Columbia River. Andrew Murdoch said the proposal is to model steelhead escapement in all of Eastern Washington (Okanogan, Wenatchee, and Methow); life history is very different between these tributaries, between spring spawners and holdovers. He said the tributaries to the Snake have a different model due to differences in life history.

Andrew Murdoch said the original motivation was to use the investment in PIT arrays for more than just steelhead. He said the steelhead viable salmonid population project is really a data gaps project—the first six data gaps have been addressed, some still exist, and some are emerging and WDFW wants to maintain flexibility to address those data gaps. The motivation to switch to tagging spring Chinook salmon would be to understand what's going on across the spring Chinook salmon evolutionarily significant unit and to develop a model to observe salmon recovery trends. He said the motivation is to leverage the fish data in the Wenatchee Basin to influence project prioritization.

Greg Mackey asked of the arrays that are critical for the OLAFT PIT-tag model, are any contracted through Biomark? Andrew Murdoch said no, none in the Methow. Mike Tonseth said WDFW is a subcontractor to Biomark for only the arrays originally funded by ISEMP; others are WDFW-funded arrays. Andrew Murdoch said there are no former ISEMP arrays in the Methow. He said there are arrays WDFW inherited from the Bureau of Reclamation (Pat Connolly's group) that required rebuilding. Andrew Murdoch said the Entiat and Wenatchee array operations will be funded but not for array maintenance. Tonseth said Okanogan arrays are a combination of WDFW and former-ISEMP arrays. ISEMP has ended, and funding sources are still unresolved.

Willard asked if PIT-tag arrays used for steelhead mark-recapture modeling will not be turned off assuming PIT tagging steelhead at OLAFT is continued? Willard said if a switch to PIT tagging spring Chinook salmon occurs, steelhead tagging would start July 1 and Chelan PUD uses the mark-recapture based estimates for tributary steelhead escapement estimates in the Wenatchee sub-basin. Willard said, assuming BPA approves WDFW using funds that are currently used for PIT tagging steelhead at OLAFT to PIT tagging Chinook at OLAFT, the funding need for PIT tagging steelhead at OLAFT would be for this year, Douglas PUD is already funding WDFW to estimate escapement into the Methow tributaries by PIT-tagging steelhead at Wells. Andrew Murdoch said stock assessment for all upper Columbia River steelhead could occur at OLAFT. He said Douglas PUD could amend contracts to allocate WDFW staff and resources differently in the Methow. Todd Pearsons said there would be a number of decisions to be made because Grant PUD shares run composition modeling at Wells with CCT. Pearsons said Grant PUD would need to think about, for example, switching to PIT tags from spawner surveys in the Okanogan River. Andrew Murdoch said this was the purpose of comparing different survey and modeling methods in the earlier presentation. Willard said Chelan PUD is committed to using the "3.0" version of the model for Wenatchee steelhead because Chelan PUD has been using this model for the past five years.

Andrew Murdoch said that when Upper Columbia wild spring Chinook salmon run size starts dropping, there are Adaptive Management Implementation Plan triggers within the Federal Columbia River Power System BiOp that requires agencies to "help out." Andrew Murdoch said tagging at OLAFT can support this and can also support adult management.

Kirk Truscott said he has 2 questions:

1. Will steelhead be PIT tagged at the OLAFT in 2019? Willard said Chelan PUD will be PIT tagging at the OLAFT in 2019.
2. Will PIT tagging at the OLAFT provide sufficient data for steelhead stock assessment for stocks upstream from Wells Dam? Andrew Murdoch said yes, there is so much overshoot at Wells that the stock assessment for Methow and Okanogan at Wells is currently inaccurate. Andrew Murdoch said PIT tagging at the OLAFT will benefit all programs upstream from Priest Rapids

Dam. He said the accuracy of using PIT-tag detections for small tributary spawning streams isn't as good but can be more accurate when data are rolled up to the distinct population segment level. Andrew Murdoch said the hope is that new high density polyethylene (HDPE) arrays are much more durable than the old polyvinyl chloride (PVC) arrays. He said he is still working with PTAGIS to reduce data management costs.

Tracy Hillman thanked Mike Hughes and Andrew Murdoch for their presentations.

E. Comprehensive Report Update

Todd Pearsons said the PUDs have been moving ahead with the 10-year analyses. The rough schedule outlined in the SOA is to provide the draft comprehensive report to the HC and HSC in 2020. Keely Murdoch asked how this is different from the 5-year analytical report. Pearsons said this is a 10-year manuscript-style report broken down into chapters developed by different authors. Keely Murdoch asked who writes the report and will there be an opportunity to comment on the report. Pearsons said the PUDs are writing the report, BioAnalysts is doing much of the statistical analysis, and that it will be provided to the Committees for review and approval. Pearsons said the comprehensive report is designed to be an integration of results and comparison to literature and other programs around the upper Columbia River.

F. NMFS Consultation Update

Brett Farman said the summer/fall Chinook Salmon bundle Environmental Assessment may be heading to NMFS headquarters today for review.

Farman said the Section 10 permits (for takes of threatened and endangered species) are being reviewed by counsel this week or next. Farman said those permits will then go out for review by the programs at the same time as they go out for public comment.

Farman said he is still waiting for an update on the steelhead program permits.

Larissa Rohrbach asked the HCP-HC and PRCC HSC Representatives what their feedback for Emi Kondo is on the dissemination of HGMP publication announcements. Truscott said Representatives and Alternatives (HCP-HC; or HSC primary list) should be notified and it is up to NMFS to disseminate announcements more broadly. Bill Gale said the distribution list should be similar to when HGMPs were sent out several years ago. Farman said NMFS is making more effort to notify interested parties than in the past. Gale asked if announcements would be posted to the Federal Register and NMFS' public website. Farman said yes.

III.Wells Hatchery Committee

A. Washington Animal Disease Diagnostic Lab Bacterial Kidney Disease Testing Update (Tentative)

Betsy Bamberger said the WADDL is able to report raw optical density (OD) values resulting from BKD assays. WADDL has revised protocols in use by federal hatcheries. Bamberger said Douglas PUD still needs to consider differences in cost between using WADDL and WDFW laboratories for BKD testing. Mike Tonseth asked whether WADDL is still working on a go-between between their method and the state's OD threshold method? Bamberger said no, there are many differences between methods and they would already use their in-house methods. Bamberger said if a change in methods were requested from WADDL, the programs would have to be very specific about what they want WADDL to do. Tonseth said the Methow BiOp requires use of the OD values for culling decisions that are based on fixed thresholds. Bill Gale said USFWS has negotiated with WADDL to provide the raw data, but for the federal hatchery programs, the decision thresholds are not fixed, data are binned, and thresholds determined after the fact. Gale said their approach is more conservative than using a fixed threshold for culling. Bamberger said because there are no clear relationships between OD limits and clinical disease, it is more of a risk-management tool. Bamberger said the program can ask WADDL for raw data. Tracy Hillman said the state's existing thresholds are very similar to what WADDL uses for the federal programs. Bamberger said there is laboratory-to-laboratory variability. Tonseth said the BiOp for the Section 10 permit dictates the thresholds. The HC would need to recommend a deviation from the current approach.

IV. RI HC

A. Marking the Chiwawa 2018 Brood

Catherine Willard said that the brood year 2018, Chiwawa spring Chinook salmon program is supposed to be 100% wild by wild crosses for a conservation program; however, wild by wild fish currently make up only about 30% of the conservation program and the remaining 70% consists of hatchery by hatchery crosses due to not collecting enough natural-origin brood. There are currently 50,000 wild by wild-origin progeny and 125,000 hatchery by hatchery-origin progeny. Under the proposed action analyzed within the BiOp, any shortfall in Nason and Chiwawa fish to meet the safety-net program would result in use of hatchery-origin fish. The program would apply an adipose fin clip to Nason and Chiwawa safety-net fish.

Keely Murdoch said that sounds different than what was in the Spring Chinook Salmon Management Plan and the HGMP. Willard said the permits do not specifically mention marking. Willard said the bottom line should be the terms and conditions agreed to in the permits and what was analyzed in the BiOps. Mike Tonseth said this does create a problem if the management plan was the material considered when issuing the BiOp, but the BiOp seems contradictory to the management plan. Tracy Hillman asked which document are we supposed to follow if there is conflicting information among documents. Willard said she is interested in knowing what NMFS' opinion is on this issue. Tonseth said the BiOp was written to consider direct and indirect take (such as from harvest on marked fish).

Bill Gale said the first thing is to review the HGMP. The proposed action reviewed by the BiOp is supposed to summarize the HGMPs. Willard said that Craig Busack may be the best person to answer our questions because he was one of the authors of the BiOp.

Hillman asked if we need NMFS to interpret the documents and provide guidance on what should be done. Gale said yes, but if there is conflicting guidance. The HCs needs to come to consensus on what to do. Brett Farman said his inclination is to mark fish based on origin of the brood, but the Committees should review the documents to understand if that was implied and expressed. Farman said he will discuss the issue with Amilee Wilson and Craig Busack to understand the original intent of the marking direction in the BiOps.

Tonseth said a follow-up discussion needs to be had after: 1) all are able to review the BiOps, HGMPs, and Management Plan; and 2) Tonseth gets information from Chuck Aldrich (WDFW) on timing of tagging to set up the timeline for a follow-up discussion on marking. Tonseth said this decision will affect the 2018 brood and the 2019 NOR shortfall. Tonseth said the timeline is to tag in summer 2019, but the outreach has started in order to reserve the tagging trailer.

Tonseth said he will collect all documents being discussed (Spring Chinook Salmon Management Plan, HGMPs, Permits, and BiOps) and send them to Larissa Rohrbach for distribution. Hillman said there should be a location on the Extranet where all these documents should be filed. Rohrbach said she would determine the appropriate place for these resources on the Extranet.

Keely Murdoch stated that after recalculation of the Chiwawa program, which resulted in a smaller production number, she thought the number of required natural-origin brood needed for the program would be met, but it has not been met. Willard stated that the committee should consider if it makes sense to collect spring Chinook at Tumwater Dam that are very likely genetically Chiwawa fish (Willard stated the genetic assignments from 2018 which included 38 out of 60 samples typing back to the Chiwawa at 90% or greater) and put them back in the river and hope that they are trapped at the Chiwawa weir. The natural-origin brood target has only been met in one out of five years of collecting Chiwawa brood at the Chiwawa weir due to meeting the bull trout encounter rate and low natural-origin spring Chinook returns. Willard said the Committees need to continue the conversation on where the broodstock for Chiwawa will come from.

Gale said there is a philosophical question at hand about whether hatchery-origin fish used to back-fill the conservation quotient are in fact "safety-net" fish (and therefore tagged by ad-clipping) or should all conservation fish be ad-present regardless of origin. Gale said the original intent of the programs was to ensure a set quotient of fish would escape harvest (by not ad-clipping them).

Tonseth said it is important to understand which fish would be moved up-river for spawning. Tonseth said if the program is producing fewer conservation fish, in subsequent years there could be an effect on PNI. Keely Murdoch said the original intent was to ensure that it would be a rare occurrence to move hatchery fish into the conservation program. The assumption was that the NOR run would increase over time; the current limitation on NORs was not forecasted. Willard said there are natural-origin fish that are passed over Tumwater that could be retained for conservation programs. Willard said there are genetic implications of using the F2 generation from safety-net fish in the conservation program

Tonseth said WDFW does not have an issue with moving more hatchery fish into the conservation program. He said the 3-population model should be used to determine how PNI will be affected if you allow more safety-net fish on the spawning grounds. Gale said if you use the Methow as an example, WNFH partial percentage of hatchery origin broodstock is no more than 50% and the 3-population PNI allowed them to conclude that they should strive to have less than 5% safety-net fish on the spawning ground to maintain percentage of hatchery origin broodstock targets. Tonseth said the Chiwawa hatchery program is 100,000 fish, which is much smaller than the Methow program. Gale said the decision depends on the proportion of safety-net fish on the spawning grounds, not the absolute numbers. Gale said the low percentage of natural origin broodstock composition of the safety-net fish will have a higher effect on PNI than the high percentage of natural origin broodstock of the conservation program. Pearsons said if you have empirical information about relative reproductive success it may not be necessary to use PNI, which is a theoretical number.

V. PRCC HSC

A. Approve the February 20, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the draft February 20, 2019 meeting minutes as revised.

Larissa Rohrbach reminded PRCC HSC members to return comments on the Priest Rapids Hatchery M&E Implementation Plan to Todd Pearsons by March 25, 2019.

B. Approve Broodstock Collection Protocols for PRCC Programs – DECISION ITEM

Tracy Hillman said the PRCC program Protocols will be approved over email following distribution of a final revised version as will be done by the HCP-HCs.

Todd Pearsons said the outcome of a discussion by the Joint Fisheries Parties about marking Nason conservation program fish should later be brought back to the HSC. Mike Tonseth said there will be overlap with the Chiwawa marking discussion so the topic should be revisited by the HSC and HCP-HCs.

C. Review and Re-Scope the White River Memorandum

Tracy Hillman received a memorandum from Elizabeth McManus (Ross Strategic) regarding the history of PRCC HSC involvement on the topic of re-initiating a White River spring Chinook salmon hatchery program. Hillman said he talked to Craig Busack, who committed to spending time this summer to address this topic with the PRCC HSC.

As a bit of background, Keely Murdoch said in the process of considering the Lake Wenatchee proposal (on which the PRCC ultimately voted not to proceed), the PRCC identified data needs with the intent to issue a Request for Proposals (RFP) to address those data needs. Keely Murdoch said it was her understanding that Curt Dodson (Grant PUD) tasked the PRCC HSC to develop an RFP based on those data needs. Bill Gale and Peter Graf said their interpretation of the PRCC's guidance was to determine if an RFP was needed. Gale said there was no written guidance from the PRCC, so it is unclear what they want.

Keely Murdoch suggested using the word "re-scope" if the goal is a consensus memorandum from the HSC. She said it is difficult to come to consensus on what type of data she will need to make the decision and to secure the support of her upper management. Keely Murdoch said that if that recommendation is not to start a hatchery program, there needs to be some good reasons why and good alternatives. For the YN, getting to recovery is the ultimate goal and the National Oceanic and Atmospheric Administration (NOAA) has signaled to the YN the importance of the White River. Ultimately, we may need to provide other recommendations that could be used as an alternative to achieve recovery of the White River aggregate to show why the recommendation not to restart the hatchery program makes sense. Keely Murdoch said there is difficulty coming to consensus because the data needed to inform one representative's particular program is not the same as for another. Graf said the solution may be a memorandum that is not a consensus memorandum. Graf said this does not have to be the last say. At any time, the HSC can add to this memorandum and revisit it. Gale said the current version of the memorandum highlights the areas of non-consensus.
Keely Murdoch said the memorandum currently does not inform why there is non-consensus.

Todd Pearsons suggested appending information that is not evident in the memorandum that communicates each party's interests and needs for a decision to be made in the future. Hillman said each entity could identify the minimum data or information that is needed to make a decision. Hillman said the memorandum already provides a lot of this information in tables. Gale said he does not like the idea of each agency providing their data needs. Gale asked why the HSC representatives wouldn't just communicate the needs back up through each PRCC representative for consideration by the PRCC.

Pearsons said there are topics where consensus would never be achieved because there are probably true differences in opinion among the entities. Graf said those differences are fundamental to the scope of starting a new hatchery program and include each agency's philosophical approach to mitigation. Keely Murdoch said there may be other ways to increase the productivity of the White River spawning aggregate. She said there is agreement that the White River aggregate is still an important piece of recovery of the species. Mike Tonseth said this principle is in the Recovery Plan, which was adopted by NMFS.

Tonseth asked what the intention is of the 2013 SOA. Did it include identifying data gaps or providing alternatives to a hatchery program? He added, there is a need to ask the PRCC for clarity. Pearsons said he did not read text about providing alternatives to restarting the White River hatchery program in the SOA and GPUD folks that negotiated the SOA said that alternative mitigation was not part of the agreement. Keely Murdoch said there is not a difference of interpretation of the SOA on whether or not to restart a White River program.

Keely Murdoch said there are two topics that would prevent a decision to restart a White River hatchery: 1) shorelines permitting with Chelan County due to challenges complying with the Washington State Shoreline Management Act; and 2) broodstock source. She read the revised Shorelines Management Plan in the meeting that now has new language that is less restrictive for aquaculture for the purposes of recovery. Gale said previously Chelan County was responding to public perception of aquaculture and its constituents. Tonseth said that is a political aspect and not a technical aspect. The HSC was tasked with considering the technical aspect.

Pearsons asked preliminarily if any Party is going to promote the idea of a White River spring Chinook salmon hatchery program? Keely Murdoch said she doesn't know. Pearsons said there will be several large datasets arising from M&E work that will inform this decision. Keely Murdoch agreed but said data are lacking for understanding juvenile Chinook salmon survivability through Lake Wenatchee and what the ecological mechanisms are that are limiting White River Chinook salmon. Hillman asked whether any decision triggers have been drafted ("if this, then that" type of language). For example, if you find high predation rates in the lake on White River Chinook salmon by bull trout, would that mean no hatchery program should be pursued? Hillman asked whether the HSC could make the decision. Keely Murdoch said the HSC will make the decision informed by recommendations from an expert panel.

Pearsons said a lot was invested in PRCC HSC discussions on the White River program in the past without much tangible benefit. Hillman said an alternative approach that is not necessarily HSC consensus is to provide lists of minimum data needs from each Party. The minimum list would be much more stripped down from the existing list. Hillman suggested that if the minimum was identified, the Parties might find more consensus.

Gale asked if there is a timeline for this? Keely Murdoch said the decision needs to be made by 2026; the timeline for achieving consensus and involving an expert panel by 2026 may start now if 3 to 4 years of data collection is needed prior to 3 years of committee and expert consideration. Tonseth said the current permits expire in 2026 and no current permit would cover the 2026 brood. A new permit and consultation would be needed. Pearsons said two things could happen: 1) the HSC could decide they don't want to restart a hatchery program, which could restart a discussion on alternatives; or 2) the decision does not need to be made until 2026 when the expert panel is convened. Grant PUD would not be supportive of investing in facility work planning before a decision about restarting a program and that won't be made until 2026.

Hillman said Craig Busack indicated that NOAA needs to provide an opinion on the status of the White River spring Chinook salmon aggregate. Graf said because there is no timeline on this memorandum, he suggested we wait until Busack re-engages with HSC. Keely Murdoch suggested asking the PRCC for additional guidance before Busack re-engages.

Hillman will ask Denny Rohr (PRCC Facilitator) to provide written instructions from the PRCC on what exactly the PRCC wants the HSC to do. HSC Representatives will assemble their list of minimum data or information needs to make a decision on the White River program.

VI. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are on April 17, 2019, at Grant PUD; May 15, 2019, at Grant PUD; and June 19, 2019, at Grant PUD.

Subject: **FINAL HCP HC and PRCC HSC APPROVED UPPER COLUMBIA RIVER 2019 BY SALMON AND 2020 BY STEELHEAD HATCHERY PROGRAM MANAGEMENT PLAN AND ASSOCIATED PROTOCOLS FOR BROODSTOCK COLLECTION, REARING/RELEASE, AND MANAGEMENT OF ADULT RETURNS**

The attached protocol was developed for hatchery programs rearing spring Chinook salmon, summer Chinook salmon, Coho salmon, and summer steelhead associated with the mid-Columbia HCPs; spring Chinook salmon, summer Chinook salmon and steelhead programs associated with the 2008 Biological Opinion for the Priest Rapids Hydroelectric Project and Salmon and Steelhead Settlement Agreement (FERC No. 2114); and fall Chinook salmon consistent with Grant County Public Utility District and Federal mitigation obligations associated with Priest Rapids and John Day dams (ACOE funded), respectively. These programs are funded by Chelan, Douglas, and Grant County Public Utility Districts (PUDs), and ACOE, and are predominately operated by the Washington Department of Fish and Wildlife (WDFW) with the exceptions of: 1) the Omak Creek/Okanogan Basin steelhead broodstock collection, and acclimation/release of Omak Creek steelhead, which is implemented by the Confederated Tribes of the Colville Reservation (CTCR), and 2) The Wells and Methow fish hatcheries operated by Douglas PUD.

This protocol is intended to be a guide for 2019 collection of salmon (19BY) and steelhead (20BY) broodstocks in the Methow, Okanogan, Wenatchee, and Columbia River basins. It is consistent with previously defined program objectives such as program operational intent (i.e., conservation and/or harvest augmentation), mitigation production levels (e.g., HCPs and Priest Rapids Salmon and Steelhead Settlement Agreement/2008 BiOp), changes to programs as approved by the HCP-HC and PRCC-HSC, and to comply with ESA permit provisions, USFWS consultation requirements.

Notable in this year's protocols are:

- Continuing for 2019, no age-2 or 3 males will be incorporated into spring or summer/fall Chinook programs unless necessary to maintain effective population size (minimum female to male ratio of 1:0.75; conservation programs only) and to minimize the necessity of using hatchery origin males in lieu of.

- Elimination of fall adult hatchery steelhead collections for the Methow Safety Net (MSN), Columbia Safety Net (CSN), and Okanogan programs. In-season run escapement forecasting will be used to determine if some level of fall broodstock collection will be needed for the CSN program to ensure the production obligation can be met. Otherwise the default brood collection period will be spring 2020.

- Continuation of spring Chinook trapping efforts at the Wells Dam East and West ladder traps consistent with 2018 operations.

- Inclusion of Appendix I, which summarizes program specific rearing/release plans (if available) outside the body of the protocols.

- Inclusion of Appendix J, which summarizes 2019BY spring and summer Chinook disease management plans.

- Inclusion of Appendix K: BY19 YN UCR coho broodstock plans.

- Expansion of Appendix G to include species/program specific management plans for managing surplus juvenile spring Chinook and summer steelhead.

- Continued inclusion of Appendix H, which describes a draft preferred approach to integration of the Methow conservation steelhead programs as well as minimize the potential for or increase the risk of a Ryman-Laikre effect in the Twisp River watershed.

- Chelan Falls broodstock collection will be prioritized at Wells Dam volunteer trap (WDVT), sufficient to meet the entire Chelan Falls yearling program of 576K while concurrently piloting alternate broodstocking methodologies. Adults collected via a temporary weir within the Chelan River Habitat Channel and beach seining in the Chelan Tailrace fail may be used to offset the number of brood needed at Wells FH if timing and fish condition are supportive of retaining them. In the event Wells FH and the two proposed pilot efforts cannot secure the appropriate number of summer Chinook broodstock for the Chelan Falls program, other locations (as determined by the Hatchery Committees) may be used. .

- Collection of surplus hatchery origin steelhead from the Twisp Weir (up to 25% of the required broodstock) to produce the 100K Methow safety-net smolts (up to 17 adults). The remainder of the broodstock (51) will be WNFH returns collected at WNFH (or by angling/trapping for WNFH program) and/or Methow Hatchery and surplus to the WNFH program needs. Collection of Wells stock may be used if WNFH and Twisp returns are insufficient. The collection of adults will occur in spring of 2020.

- Summer Chinook collections at Wells Dam ladder traps to support the CJH integrated program (adipose present non-wired adults) and Well Dam ladder traps and the Wells Hatchery volunteer trap to support the CJH segregated program (adipose clipped adults) may occur if CCT broodstock collection efforts fail to achieve broodstock collection objectives.

- Spring Chinook eggs identified through CWTs from ad-clipped + CWT CJH segregated returns that occur during spawning at Methow FH or WNFH may be transferred to the CJH Program for inclusion in the CJH spring Chinook segregated program.

- Reduction of NO fall Chinook broodstock from the OLAFT from 1,000 to 650.

- Targeted collection of about 600 adipose present, non-coded wire tagged fall Chinook using hook-and-line efforts in the Hanford Reach.

- Continuation of Tumwater trap operations to facilitate lamprey passage. Using Rocky Reach and Rock Island lamprey passage data as a surrogate, it is proposed to open the Tumwater Dam fishway to passage between 10PM and 6AM daily from September 1 to mid-December. This should allow open passage for at least 60%-70% of the lamprey while still accommodating coho and steelhead broodstocking and steelhead adult management. Because this is the second year to operate under this schedule, some in-season adjustments may need to be made based on lamprey observations (during trapping periods) and the magnitude of steelhead adult management required.

- Addition of the 2019 YN UCR coho broodstock collection plans (includes the DPUD Coho program brood).

These protocols may be adjusted in-season, based on actual run monitoring at mainstem dams and/or other sampling locations. Additional adaptive management actions as they relate to broodstock objectives may be implemented as determined by the HCP-HC or PRCC-HSC and within the boundaries of applicable permits.

Also included in the 2019 Broodstock Collection Protocols are:

Appendix A: 2019 BY Biological Assumptions for UCR Spring, Summer, and Fall Chinook and 2020 BY Summer Steelhead Hatchery Programs
Appendix B: Current Brood Year Juvenile Production Targets, Marking Methods, Release Locations
Appendix C: Return Year Adult Management Plans
Appendix D: Site Specific Trapping Operation Plans
Appendix E: Columbia River TAC Forecast
Appendix F: Annual Chelan, Douglas, and Grant County PUD RM&E Implementation Plans
Appendix G: DRAFT Hatchery Production Management Plan
Appendix H: DRAFT Preferred Alternative for 2020 BY and beyond, Methow Sub-basin Conservation Steelhead Programs
Appendix I: Program Specific Rearing and Release Descriptions
Appendix J: 2019 BY spring and Summer Chinook Disease Management Plans
Appendix K: 2019 YN Coho Broodstock Collection Plans

Methow River Basin

Coho - Douglas PUD Program- Methow Basin – Twisp River

The Douglas PUD (DPUD) coho program began with brood year 2018. The target release is 37,000 yearling coho. Broodstock are collected for the Yakama Nation (YN) and the DPUD program collectively by the YN at Wells Dam and Hatchery, Winthrop National Fish Hatchery (WNFH), and Methow Hatchery. The broodstock are transported to, held, and spawned at WNFH. The DPUD program obtains eggs to rear at Wells Hatchery from WNFH. See Appendix K for a complete description of the YN coho program and broodstock collection.

Spring Chinook

Inclusion of natural-origin fish in the broodstock will be prioritized for the aggregate conservation program in the Methow Basin. Collections of natural-origin fish will not exceed 33% of the Methow Composite (i.e., non-Twisp) and Twisp natural-origin run escapement consistent with take provisions in Section 10 (a)(1)(A) Permits 18925 and 20533.

Hatchery-origin spring Chinook, if needed, will be collected in numbers excess to program production requirements to facilitate BKD management, comply with ESA Section 10 permit take provisions, and to meet programmed production shortfalls. Based on historical Methow FH spring Chinook ELISA levels above 0.12, any hatchery origin spring Chinook broodstock collection will include hatchery origin spring Chinook in excess to broodstock requirements by approximately 20% (based upon the most recent 5-year mean ELISA results for the Methow/Chewuch/Twisp programs). For purposes of BKD management and to comply with maximum production levels and other take provisions specified in ESA Section 10 permits 18925 and 20533, culling will include the destruction of eggs from hatchery-origin females with ELISA levels greater than 0.12 and/or that number of hatchery-origin eggs required to maintain an aggregate production of 223,765 yearling smolts. Culling of eggs from natural-origin females will not occur unless their ELISA levels are determined by DPUD Fish Health and the Wells, Rocky Reach, and Rock Island HCP's- and the Priest Rapids CC - HSC to be a substantial risk to the program. Progeny of natural-origin females with ELISA levels greater than 0.12 may be differentially tagged for evaluation purposes. Annual monitoring and evaluation of the prevalence and level of BKD and the efficacy of culling returning hatchery- and natural-origin spring Chinook will continue and will be reported in the annual monitoring and evaluation report for this program.

WDFW genetic assessment of natural-origin Methow spring Chinook (Small et al. 2007) indicated that Twisp natural-origin spring Chinook can be distinguished, via genetic analysis, from non-Twisp spring Chinook with a high degree of certainty. The Wells HCP Hatchery Committee accepted that Twisp-origin fish could be genetically assigned with sufficient confidence and that natural origin collections can occur at Wells Dam. Scale samples and non-lethal tissue samples (fin clips) for genetic/stock analysis will be obtained from adipose-present, non-CWT, non-ventral-clipped spring Chinook (suspected natural-origin spring Chinook) collected at Wells Dam, and origins assigned based on genetic analysis. Natural-origin fish retained for broodstock will be PIT tagged (pelvic girdle) for cross-referencing tissue samples/genetic analyses. Tissue samples will be preserved and sent to the WDFW genetics lab in Olympia Washington for genetic/stock analysis. Spring Chinook collected from Wells will be held until genetic analysis results are received then transferred to and retained at Methow Hatchery and spawned for each program depending on results of DNA analysis. Brood collection of NORs at Wells will be based upon assignment of Twisp NORs to the Twisp program and non-Twisp NORs being used to support Methow and Chewuch River releases. Spring Chinook collected at Methow Hatchery will be held at MFH until genetic analysis results are received and then handled accordingly.

The number of natural-origin Twisp and Methow Composite (non-Twisp) spring Chinook retained will be dependent upon the number of natural-origin adults returning and the collection objective limiting extraction to no greater than 33% of the natural-origin spring Chinook return to the Methow Basin. Natural origin fish not assigning to the Twisp or Methow Composite will be released back into the Columbia River.

Weekly estimates of the passage of Wells Dam by natural-origin spring Chinook will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%. Hatchery origin adults trapped at the Winthrop NFH may be included, if needed, in the event of broodstock shortfalls.

Pre-season run-escapement of Methow-origin spring Chinook to Wells Dam during 2019 is estimated at 1,803 spring Chinook, including 1,018 hatchery and 785 natural origin spring Chinook (Table 1 and Table 2). In-season estimates of natural-origin spring Chinook will be adjusted proportional to the estimated returns to Wells Dam at weekly intervals and may result in adjustments to the broodstock collection targets presented in this document. In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs, within the constraint of not collecting more the 33% of the natural origin spring Chinook. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

The following broodstock collection protocol was developed based on BKD management strategies, projected return for BY 2019 Methow Basin spring Chinook at Wells Dam (Table 1 and Table 2), and biological assumptions listed in Appendix A.

The 2019 aggregate Methow spring Chinook broodstock collection will target up to 128 adult spring Chinook (18 Twisp, 110 Methow; Table 3). Based on the pre-season run forecast, Twisp fish are expected to represent about 7.9% of the CWT tagged hatchery adults and 22% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin spawning escapement to the Twisp, the 2018 Twisp origin broodstock collection will total 18 wild fish, representing 100% of the broodstock necessary to meet Twisp program production of 30,000 smolts. Methow Composite fish are expected to represent about 34% of the CWT tagged hatchery adults and 78% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin recruits, the 2019 aggregate Methow/Chewuch broodstock collection will total 110 natural-origin spring Chinook. Broodstock collected for the aggregate Methow conservation programs represents 100% of the broodstock necessary to meet the Methow programs production of 223,765 smolts. The Twisp River releases will be limited to releasing progeny of broodstock identified as wild Twisp and or known Twisp hatchery-origin fish, per ESA Permit 18925. The MetComp releases will include progeny of broodstock identified as wild non-Twisp origin (or known Methow Composite hatchery origin if needed to meet shortfalls in the production goal) fish. Age-3 males ("jacks") will not be collected for broodstock unless needed to meet effective population goals and minimize contribution of hatchery fish within the conservation program.

Table 1. Brood year 2014-2015 age class-at-return projection for wild spring Chinook above Wells Dam, 2019.

Brood Year	Smolt Estimate		Age-at-return							
			Twisp sub-basin				Methow sub-basin			
	Twisp[1]	Methow Basin[2]	Age-4	Age-5	Total	SAR[3]	Age-4	Age-5	Total	SAR[4]
2014	28,380	41,353	164	**25**	210	0.0074	707	**145**	906	0.0219
2015	22,738	26,491	**131**	20	168	0.0074	**453**	92	580	0.0219
Estimated 2019 Return			**131**	**25**	**156**		**453**	**145**	**598**	

[1] *Smolt estimate is based on sub-yearling and yearling emigration (Charlie Snow, personal communication).*
[2] *Estimated Methow Basin smolt emigration based on Twisp Basin smolt emigration, proportional redd deposition in the Twisp River and Twisp Basin smolt production estimate.*
[3] *Geometric mean Twisp NOR spring Chinook SAR to Wells Dam estimated using natural origin PIT tag returns (BY 2003-2009; David Grundy, personal communication).*
[4] *Geometric mean Methow NOR spring Chinook SAR to Wells Dam estimated using natural origin PIT tag returns (BY 2003-2009; David Grundy, personal communication).*

Table 2. Brood year 2014-2016 age class and origin run escapement projection for UCR spring Chinook at Wells Dam, 2019.

Table 3. Number of broodstock needed for the combined Methow spring Chinook conservation program production obligation of 223,765 smolts, collection location, and mating strategy.

By obligation	Production target	Number of Adults		**Total**		
		Hatchery	Wild			
Chelan PUD	60,516		17F/17M	**34**		
Douglas PUD	29,123		9F/9M	**18**		
Grant PUD	134,126		38F/38M	**76**		
Total	**223,765**		**64F/64/M**	**128**		
By program		Number of Adults			Collection location	Mating protocol
		Hatchery	Wild	**Total**		
Twisp	**30,000**		**9F/9M**	**18**	Wells Dam/Twisp Weir	2x2 factorial
MetComp	**193,765**		**55F/55M**	**110**	Wells Dam/Methow Hatchery	2x2 factorial
Total	**223,765**		**64F/64M**	**128**		

Trapping at Wells Dam will occur at the East and West ladder traps beginning on May 1, or at such time as the first spring Chinook are observed passing Wells Dam, and continue through June 30, 2019 (collection quotas will be prioritized for the May 1-June 22 time frame). Spring Chinook broodstock collection and stock assessment sampling activities authorized through the 2019 Douglas PUD Hatchery M&E Implementation Plan will utilize a combination of trapping on the East and West ladders as per the detailed descriptions of the modified trapping operations for spring Chinook collection in Appendix D. Natural origin spring Chinook will be retained from the run, consistent with spring Chinook run timing at Wells Dam (weekly collection quota). Collection goals will be developed by Wells M&E and DPUD staff to identify the most appropriate spatial and temporal approach to achieving the overall brood target. All natural origin spring Chinook collected at Wells Dam for broodstock will initially be held at Wells FH pending genetic results and then transferred to Methow FH. Fish collected at MFH will remain at MFH or be transferred to WNFH.

Collection of ad-clipped +CWT spring Chinook adults may occur from facilities in the Methow basin and/or Wells Dam. These alternative collection locations will only be used if USFWS broodstock collection efforts fail to achieve broodstock collection objectives for the CJH 10j program
Trapping at the Twisp Weir for spring Chinook may begin May 1 or at such time as spring Chinook are observed passing Wells Dam and may continue through August 23. The trap may be operated up to seven days per week/16 hours per day (provided it is manned during active trapping).

However, trapping at the Methow Hatchery Outfall trap may continue beyond the Twisp Weir operations as needed to meet basin wide PNI/pHOS objectives. Hatchery-origin adults captured at the Methow Hatchery Outfall (surplus to the Methow Hatchery program) will be: 1) used for adult out-planting to increase natural production and secondarily, 2) transferred to the WNFH for incorporation into WNFH brood, or 3) removed as surplus as to meet ESA permit requirements of both facilities.

Steelhead

Douglas PUD and Grant PUD steelhead mitigation programs above Wells Dam utilize adult broodstock collections from multiple sources and locations (Table 5). Broodstock for the conservation programs (USFWS and DPUD) is achieved via angling in the Methow Basin and trapping at the Twisp Weir (as needed), respectively. Broodstock for the Methow safety net program is achieved primarily through returns to WNFH (including hook and line-caught HOR steelhead) and surplus fish removed at Methow Hatchery and the Twisp Weir. Broodstock for the Columbia safety net is achieved primarily through adult returns to the Wells volunteer trap or secondarily through surplus adults collected at MFH and WNFH. Broodstock for the Okanogan conservation program (GPUD) is achieved via Omak weir, dip-netting and or box traps in tributaries to the Okanogan River and hook-and-line in the mainstem Okanogan and tributaries. Broodstock collected for the Okanogan safety net program (GPUD) is primarily collected from Omak Creek but also in the Okanogan River and tributaries to the Okanogan River via box traps, traditional dip-net methods and hook-and-line angling, and at Wells FH via the volunteer trap. Generally incubation/rearing occur for the DPUD conservation program, Methow safety net, Okanogan, and Columbia River releases at Wells Fish Hatchery (FH). Methow Hatchery may be used to temporarily hold broodstock that are ultimately transferred to Wells Hatchery or WNFH. In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs, within the constraint of not collecting more the 33% of the natural origin summer steelhead. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

Presently the HCP HC and Joint Fisheries Parties are continuing to work to develop, approve, and implement an alternative to past programmatic approaches to more fully coordinate the collective Methow sub-basin steelhead conservation programs as well as address concerns over potential Ryman-Laikre (RL) effects in the Twisp River watershed. Some elements of a preferred alternative (see Appendix H), are still being piloted for the 2020 brood. The HC parties have not approved a long-term plan for the Twisp program pending results of the 2018 and 2019 pilot years brood collection efforts. The broodstock collection protocols for the 2020 brood will remain the same as those described in the 2018 Broodstock Collection Protocols. If the alternative in Appendix H or other alternative is approved prior to implementation of the 2020 BY conservation programs, the 2019 Broodstock Collection Protocols will be updated to reflect the new direction.

Specific program brood sources are structured as follows:

Broodstock collection for the DPUD and GPUD summer steelhead programs is designed to meet program production goals while minimizing the probability of producing overages. The following broodstock collection logic provides a step-by-step process whereby DPUD, GPUD, and WNFH summer steelhead broodstock will be collected.

1. February 2020-April 2020: Hook-and Line collections in the Methow mainstem: target sufficient natural origin summer steelhead for the Twisp Conservation component (24,000 release; 13 broodstock collected downstream of Twisp) and the WNFH (up to 200,000 release; up to110 broodstock collected throughout Methow mainstem). These natural origin fish are to be transported to WNFH, spawned collectively, and a portion of the progeny sufficient to meet the 24,000 release target will be transferred to Wells Hatchery as eyed eggs. By-catch of hatchery origin fish will be retained as broodstock for the WNFH program (Ad+CWT), the Methow Safety-Net (CWT only, Ad+CWT), and the Columbia Safety-Net (Ad only, Ad_CWT), as needed. Adults in excess of broodstock needs will be managed as surplus. Go to #2.

2. March-May 2020: Twisp Weir collection. Target sufficient natural origin summer steelhead for the Twisp Conservation component (13 adults; 24,000 release). Hatchery-origin fish to be removed at a rate to meet pHOS management target. CWT-only fish to be used as broodstock for the Methow Safety-Net up to 25% (approximately 14 broodstock). Additional CWT-only broodstock may be used in the Columbia Safety-Net. CWT+Ad may be used in the Columbia Safety-Net. Go to # 3.

3. March-May 2020: WNFH Volunteer Channel and Methow Hatchery Volunteer channel. Natural origin fish may be collected if present and included in the WNFH and Methow River collected component of the Twisp Conservation Program. Hatchery origin fish will be collected and used as broodstock in the WNFH program (Ad+CWT), Methow Safety-Net program (Ad+CWT), and the Columbia Safety-Net program (Ad+CWT, Ad only). Such fish may be used to augment the fish previously collected described in #s 1 and 2, above. Adults in excess of broodstock and escapement needs will be managed as surplus. Go to #4.

4. March-May 2020: Okanogan River Basin collections to target, up to 58 adult steelhead, consistent with provisions included in the CTCR Tribal Resource Management Plan (TRMP) BiOP. Go to #5.

5. March-May 2020: The Wells Volunteer Channel will be used to collect AD+CWT, Ad only, and CWT only hatchery origin adult summer steelhead to be used as backfill for Methow Safety-Net, Columbia Safety-Net, Okanogan Program, and WNFH program (if desired by USFWS) should any of these program lack sufficient broodstock for the collections described above. Adult hatchery origin steelhead in excess of broodstock needs will be surplused.

Twisp River – Conservation Releases

Due to the recent increased concern for inbreeding depression risk (Ryman-Laikre) for the Twisp program as a result of low N_e and other confounding issues, the design of the Twisp program is currently under review.

The HC and JFP are working to redefine the scope and nature of the 2019 brood and future Twisp program. Parties will complete this task no later than October 1 (or sooner) of the current year such that an approved plan can be implemented.

The current plan (BY 2020) collects approximately 13 natural origin fish as broodstock from the Methow Mainstem (hook and line) and approximately 13 natural origin fish as broodstock from the Twisp River (weir).

Wells Hatchery – Methow River Release

The Wells Hatchery Methow River release (Methow safety net program) uses locally collected hatchery origin broodstock representative of the Twisp and WNFH conservation programs and as needed, the Methow safety-net program. Adults are collected in concert with adult management and broodstock collection (including hook-and-line) activities at the Twisp Weir, Methow Hatchery, and WNFH. As a backup strategy, hatchery origin broodstock may be collected from Wells Hatchery Volunteer Channel in spring 2020 if other broodstock collection measures fall short. Beginning with the 2018 release, fish will be truck planted at Effy Bridge (RKM 13) in the lower Methow.

Wells Hatchery-Columbia River Release

The Wells Hatchery Columbia River releases will use progeny returns from the Methow Safety-Net broodstock (described above). The remaining production for the Columbia Safety-Net may include hatchery origin broodstock collected via hook-and-line in the Methow River, Twisp Weir, adult returns to the Methow Hatchery and Winthrop NFH, and may be augmented with fish collected in spring 2020 from the Wells Volunteer channel if needed to fulfill the program. Surplus eggs and/or fry from the Columbia and Okanogan broodstock may be utilized for other programs in the upper Columbia. Fish are released to the Columbia River, immediately downstream of Wells Dam.

Winthrop NFH – Methow River Release

The USFWS Methow River release will primarily use natural-origin (NO) fish collected through hook-and-line collection efforts in the Methow River each spring. In the event NO collection falls short of the target, WNFH hatchery-origin returns will be prioritized, followed by Methow safety-net hatchery returns. Transfer of adult and/or gametes/eggs between program will be carefully choreographed to ensure fish are being utilized in the most efficient and effective manner. Fish may be released throughout the Methow basin.

Okanogan River and Tributary Releases

The Okanogan River conservation program uses a combination of natural- and hatchery-origin adults collected in Omak Creek and elsewhere in the Okanogan Basin through CCT collection efforts. Surplus eggs and/or fry from the Okanogan River program broodstock may possibly be utilized for other programs in the upper Columbia or otherwise surplussed at the earliest time when overages are apparent.

Should the Okanogan Basin spring period collection fail to achieve sufficient broodstock to meet programmed production, steelhead will be collected from the Wells Hatchery volunteer ladder in the spring of 2020, sufficient to meet broodstock needs. Fish with positive CWT or PIT tag for Okanogan origin will be the priority to fill the shortfall in broodstock, followed by unknown hatchery origin fish.

Steelhead programs located upstream of Wells Dam and at Wells Hatchery are presented in Table 4.

Table 4. 2020 brood year Steelhead Programs at Wells Hatchery and Upstream of Wells Dam

Program	Hatchery	Owner	Release Location	Release Target	Broodstock Collection Locations
DPUD Conservation[2]	WNFH – 2S; Wells Hatchery 1S	Douglas PUD	Twisp River @ Buttermilk Bridge, Methow basin @ WNFH or other location as determined by the HCP-HC	48,000 (S_1)	Twisp Weir and Methow basin (angling)
Methow Safety-Net	Wells Hatchery	Douglas PUD	Effy Bridge – Lower Methow River	100,000	HxH: Twisp Weir (up to 25%) + WNFH Hatchery (75%) or WNFH 1st, MFH 2nd to make up balance
Mainstem Columbia Safety-Net	Wells Hatchery	Douglas PUD	Columbia River @ Wells Hatchery	160,000	HxH: Wells FH/Dam returns (1st option); Methow FH/WNFH (2nd option)
WNFH Conservation Program	WNFH	USFWS	Methow basin @ WNFH or other locations as determined by the JFP	Up to 200,000 (S_2)	Maximize use of NOR, up to 55 pair captured by hook and line in the Methow River and Spring Creek Weir.
Okanogan[1]	Wells Hatchery/ St. Mary's Pond	Grant PUD/CCT	Okanogan tributaries	100,000[1]	Okanogan Basin, Wells FH/Wells FH/Dam

[1] CCT received approval for the Okanogan steelhead HGMP as part of their Tribal Resource Management Plan in February, 2017. Omak Creek and Wells Fish Hatchery are no longer separate hatchery programs. Up to 58 broodstock (NOB or HOB) may be collected from throughout the Okanogan basin (or Wells Dam if necessary) to meet the 100k program.
[2] The DPUD Twisp conservation program is currently under re-development after detection of inbreeding depression risk. The HC and JFP have committed to developing an approved plan in sufficient time for implementation.

The following broodstock collection protocol was developed based on mitigation program production objectives (Table 6), biological assumptions (Appendix A), and the probability that sufficient adult steelhead will return in 2019/2020 to meet production objectives absent a reliable preseason forecast at the present time.

For the 2020 brood steelhead programs operating above Wells Dam, a total of 334 adults (194 natural origin and up to 140 hatchery origin adults) are estimated to be needed to fulfill the respective mitigation obligations (Table 6). To support these obligations and to ensure sufficient backup adults are available in the event spring tributary based collection efforts fall short of targets, spring 2020 trapping at Wells Dam and/or Wells FH may be implemented to selectively retain sufficient adults to backfill shortfalls in spring collections (west [and east, as necessary] ladder and volunteer trap collection; Table 5). As a note, all potential broodstock will be scanned for PIT tags at collection and PIT tagged fish will be returned to the river to meet their monitoring objective. Any adult determined to have been part of the Yakama Nation's kelt reconditioning program will be released in the vicinity it was collected.

Twisp Conservation Program (DPUD)

The HC and JFP are working to redefine the scope and nature of the 2020 brood and future Twisp program. Parties will complete this task no later than October 1 (or sooner) of the current year such that an approved plan (the current draft plan be reviewed in Appendix H) can be implemented.

Methow Safety Net Program

Up to 14 surplus hatchery-origin Twisp-stock steelhead (to meet up to 25% of the 100K Methow Safety-Net release) will be targeted at collection locations including the Twisp Weir and moved as live adults to Wells Hatchery for spawning. No less than 40 hatchery adults will be targeted at WNFH and through angling efforts, and if needed/available, Methow Hatchery volunteer traps to meet the balance of the program needs (Table 6). If collection via hook-and-line, at the Twisp Weir, and WNFH and MH traps/collection efforts are unsuccessful (Table 5) then broodstock will be trapped in the Wells Volunteer channel in spring 2020. Coordination between USFWS, DPUD, and WDFW staff will occur during the season to determine prioritization.

Methow Conservation Program (USFWS)

Approximately 110 natural origin adults (55 pair) will be targeted for retention through hook–and-line collection efforts in the Methow River (Table 6). In the event of a shortage, excess hatchery steelhead from the Twisp Weir and volunteer returns to the WNFH (including angle-caught fish) will be utilized as needed to augment WNFH broodstock. Should there be inadequate surplus steelhead from these sources, excess hatchery steelhead (presumed Methow Safety-Net origin) captured at the Methow Hatchery volunteer trap will be used to fulfill the program. Natural-Origin females will be live-spawned and reconditioned by YN.

Okanogan Conservation Program (GPUD/CCT)

Up to 58 adult steelhead will be targeted in the Okanogan Basin, including up to 100% natural-origin adults (dependent on run size and within the 33% natural origin extraction rate) (Table 5). Broodstock collected at Wells FH that are subsequently identified as Okanogan-origin will be transferred to the Okanogan program (as needed to meet program obligations). Due to unknown broodstock collection efficiencies in the Okanogan River Basin (Table 5) further broodstock shortfalls for the Okanogan may be supplemented with broodstock collected in the spring of

2020 at the Wells Fish Hatchery Volunteer Ladder and/or Wells Dam east/west ladder traps to meet the production obligation.

Table 5. Broodstock collection locations, number, and origin by program.

Program	Number of Adults[1]		Primary collection location	Backup collection location(s)	Total adult collection[1]	
	Hatchery	Wild			Hatchery	Wild
DPUD Columbia R. SN	86		Wells FH/Dam, Methow River, WNFH, Methow Hatchery, Twisp Weir	Wells Hatchery	86	
DPUD Methow R. SN	54		Twisp weir (14), Methow River, WNFH[3] (46)	Wells Hatchery/Dam	54	
DPUD Met. Conservation		26	Twisp Weir; Methow basin	NA		26
GPUD Okanogan R.	0-58[6]	0-58[7]	Omak Cr., Okanogan R. and tributaries,	Wells Hatchery/Dam[5]	0-58	(1st priority) 0-58
USFWS Methow R.		110	Methow R. WNFH[4]	Methow Hatchery	Up to 54[8]	110[8]
Total (PUD programs)	**140-198**	**26-84**			**140**	**26-84**
Total (All programs)	**140-198**	**136-194**			**140-252**	**136-194**

[1] Assumes a 1:1 sex ratio (see Table 6). Natural origin females will be live spawned and reconditioned.
[2] Primarily uses hatchery origin adults collected via the USFWS hook and line efforts for natural origin fish in the Methow River and adult returns to WNFH. May include Methow safety net adults collected via angling, or adult returns to WNFH and Methow FH.
[3] May also include excess hatchery origin adults collected via angling and at Methow FH and the Twisp Weir.
[4] Spring collection of hatchery origin steelhead as needed to meet program for the Okanogan Program. Shortfall, if encountered, to be met with Wells Hatchery Volunteer Channel collection in spring.
[5] Dependent upon number of NOR broodstock collected in the Okanogan Basin, age structure and fecundity to achieve sufficient brood for a100k smolt program for the Okanogan.
[6] Depending upon NOR abundance and trapping efficiency.
[7] Broodstock composition for the WNFH conservation program is subject to a sliding production/pNOB scale where full 200K production is targeted only when broodstock pNOB is >0.75. Under run/environmental conditions where collection is unable to support extraction of 110 NORs, HOR broodstock are incorporated subject to a sliding scale (with a minimum release of 100K) as authorized in the 2017 Biological Opinion.

Table 6. Number of broodstock needed to produce approximately 608,000 smolts for the above Wells Dam 2020 brood summer steelhead programs. Includes primary collection location(s) and mating strategy. *Broodstock totals do not include additional fish that may be collected at other locations as a backup for shortfalls from primary collection sources*.

Program	Production target/request	Number of Adults		Total	Collection location	Mating protocol
		Hatchery	Wild			
DPUD[1] Columbia R.	160,000	43F/43M		**86**	Wells FH/ Dam/Twisp Weir/	1:1
DPUD[2] Methow R.	100,000	27F/27M		**54**[4]	Twisp Weir, MFH, WNFH, Wells FH/Dam	1:1
DPUD Methow Conservation	48,000		13F/13M	**26**	Twisp Weir/Methow River	2x2 Factorial
GPUD Okanogan R.[3]	100,000		29F/29M	**58**[5]	Okanogan R./Omak Creek	1:1/2x2[7]
USFWS Conservation[8]	200,000[8]		55F/55M	**110**	Methow River[6]	2X2 Factorial
Total[4]	**608,000**	**70F/70M**	**97F/97M**	**334**		

[1] Mainstem Columbia releases at Wells Dam. Target HxH parental adults as the hatchery component.
[2] Methow River release of HxH fish produced from either adults returning from the Winthrop conservation program, adults trapped at MFH, and/or surplus hatchery adults from the Twisp weir, or Wells FH/Dam.
[3]CCT intends to achieve greater than 0.5 pNOB, but the actual number will be dependent upon run size and trap efficiency, per the HGMP. Numbers of hatchery and wild males and females in this table should not be taken as the goal or limit for any collection effort, as it could be up to 100% pNOB or pHOB.
[4] Additional hatchery adults may be collected at Wells FH to augment shortfalls in collections for the Methow safety net.
[5] Additional hatchery origin adults may be collected during the spring of 2020 at Wells Dam/Wells FH to augment shortfalls in Okanogan Basin collection efforts.
[6] Collection priority: 1) hook and line, 2) adult returns to WNFH, 3) excess adult returns to Methow Hatchery.
[7] A 1:1 mating protocol will be used for all HxH/HxW crosses within the Okanogan. The Okanogan locally-adapted natural stock (WxW) will utilize a minimum 2x2 factorial mating to minimize potential negative effects associated with a small effective population size.
[8] Production is subject to a sliding production/pNOB scale where full 200K production is targeted only when broodstock pNOB is >0.75. Under run/environmental conditions where collection is unable to support extraction of 110 NORs, HOR broodstock are incorporated subject to a sliding scale (with a minimum release of 100K) as authorized in the 2017 Biological Opinion.

Overall collection for the PUD programs will be 224 fish (Table 6) and limited to no more than 33% of the entire run and/or 33% of the natural origin return. Hatchery and natural origin collections will be consistent with the respective run-timing of hatchery and natural origin steelhead at Wells Dam, Omak Weir and the Twisp Weir. Trapping at the Wells Dam ladders may occur between 01 August, 2019 and 30 April, 2020, up to three days per week, and up to 16 hours per day, as required to meet broodstock objectives. (Appendix D). The Twisp Weir operates from early March (dependent on river conditions) through the end of the steelhead spawning run (spring Chinook trapping takes over by June 1). Trapping occurs daily for broodstock collection and gene flow management.

Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and Wells dams. Broodstock collection adjustments may be made based on in-season monitoring and evaluation. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

Summer/fall Chinook

The summer/fall Chinook mitigation program in the Methow River utilizes adult broodstock collections at Wells Dam and incubation/rearing at Eastbank Fish Hatchery. The total production level target is 200,000 summer/fall Chinook smolts for acclimation and release from the Carlton Acclimation Facility.

The TAC 2019 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2014, 2015, and 2016 spawn escapement to tributaries above Wells Dam indicate sufficient summer Chinook will return past Wells Dam to achieve full broodstock collection for supplementation programs above Wells Dam. The following broodstock collection protocol for the Methow summer Chinook program was developed based on initial run expectations of summer Chinook to the Columbia River, program objectives, and program assumptions (Appendix A).

For 2019, up to 124 natural-origin summer Chinook at Wells Dam west (and east, if necessary) ladder(s), including 62 females for the Methow summer Chinook program (Table 7). Collection will be proportional to return timing between 01 July and 15 September. Summer Chinook stock assessment will run concurrent with summer Chinook broodstock collection at the west ladder trap. Trapping may occur up to 3-days/week, 16 hours/day (48 cumulative hours per week). Age-3 males ("jacks") will not be collected for broodstock unless needed to pair with females.

Should use of Wells Dam be needed to meet any shortfalls in Chief Joseph Hatchery broodstock for summer/fall Chinook programs, the CCT will notify the HCP-HC and Wells HCP Coordinating Committee/PRCC-HSC and coordinate with Douglas PUD, Grant PUD, and WDFW to facilitate additional broodstock collection effort. Summer Chinook broodstock collection efforts at Wells Dam, should they be required to meet CJH program objectives, will be conducted concurrent with broodstock collection efforts for the Methow summer Chinook program and or steelhead collection efforts for steelhead programs above Wells Dam.

If the probability of achieving the broodstock goal is reduced based on passage at the west ladder or actual natural-origin escapement levels, broodstock collections may be expanded to the east ladder trap and/or origin composition will be adjusted to meet the broodstock collection objective. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

Table 7. Number of broodstock needed for Grant PUDs Methow summer Chinook production obligation of 200,000 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		Total	Collection location	Mating protocol
		Hatchery	Wild			
Methow	200,000		62F/62M	**124**	Wells Dam	1:1
Total	**200,000**		**124**	**124**		

Columbia River Mainstem below Wells Dam

Summer/fall Chinook

Collection at the Wells FH volunteer channel will be used to collect the broodstock necessary for the Wells FH yearling (320,000) and sub-yearling (484,000) programs.

Because of CCT concerns about sufficient natural-origin fish reaching spawning grounds and to ensure sufficient NOR's being available to meet the CCT summer Chinook program, incorporation of natural-origin fish for the Wells program or programs with broodstock originating from the Wells volunteer channel, will be limited to fish collected in the Wells volunteer channel. The program includes up to 10% natural origin broodstock. The following broodstock collection protocol was developed based on mitigation objectives and program assumptions (Appendix A).

DPUD will target 532 run-at-large summer Chinook from the volunteer ladder trap at Wells Fish Hatchery outfall for the Wells sub-yearling and yearling programs (Table 8). Due to fish health concerns associated with the volunteer collection site (warming Columbia River water during late August), the volunteer collection will begin July 1 and terminate by August 31. In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs, within the constraint of not exceeding 10% representation of natural origin fish in the summer Chinook broodstock collection. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

For 2019, broodstock collection for the Chelan Falls summer Chinook program will be prioritized at the Wells Fish Hatchery volunteer trap. The Chelan Falls Canal Trap (CFCT) was piloted from 2016 to 2018 to collect adult Chinook broodstock, but for various reasons the trapping season was truncated and the CFCT was unsuccessful, in meeting the broodstock requirements for the Chelan Falls program. Chelan PUDs assessment of the financial investment necessary to make the CFCT viable has determined it to be unfeasible at the present time.

While broodstocking efforts in 2019 will be prioritized at the Wells volunteer trap, Chelan PUD will evaluate the installation and operation of a temporary picket weir in the Chelan River habitat channel and utilizing the CCT to evaluate the feasibility of beach seining for adult Chinook in the Chelan tail race area. Specific details of these two efforts have yet to be finalized. However, if implemented and successful, adults collected will be incorporated into the Chelan Falls program and adult brood numbers from the Wells volunteer trap will be appropriately reduced.

If shortfalls in adult needs are expected and the number of females needed to meet program has not been reached by August 15th, the HCP HC will discuss whether broodstock collection may default to surplus summer Chinook collected from other HCP approved locations to make up the difference. The 2019 broodstock target for the Chelan Falls program is 390 adults (Table 8). The total production level supported by this collection is up to 576,000 yearlings for the Chelan Falls program.

In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

Table 8. Number of broodstock needed for the combined Chelan and Douglas PUD Columbia River below Wells summer Chinook production obligations of 1,380,000 smolts, collection location, and mating strategy. Also includes broodstock necessary for outside programs that rely on adult collection at Well Hatchery in 2019.

Program	Production target	Number of Adults[1]		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Wells 1+	320,000	96F/96M		**192**	Wells VC[2]	1:1
Wells 0+	484,000	170F/170M		**340**	Wells VC[2]	1:1
Chelan Falls 1+	576,000	195F/195M		**390**	Wells VC[2]	1:1
Total	**1,380,000**	**461F/461M**		**922**		

[1] The number of adults collected for these programs may indirectly incorporate natural origin fish; however, because they are volunteers, the number is likely to be less than 10% of the total.
[2] Wells Hatchery volunteer channel trap.

Wenatchee River Basin

In 2019 the Eastbank Fish Hatchery (FH) is expecting to early rear spring Chinook salmon for the Chiwawa River and Nason Creek acclimation facilities located on the Chiwawa River and Nason Creek. The program production level target for the Chiwawa program (Chelan PUD obligation) in 2019 is 144,026 smolts, and based upon the biological assumptions (Appendix A) will require a total broodstock collection of about 72 natural origin spring Chinook (Table 10). The spring Chinook production obligation as currently described in the BiOp and Section 10 permit for Grant PUD in the Wenatchee Basin is 223,670 smolts (125,000 conservation and 98,670 safety net) and based upon the biological assumptions (Appendix A) will require a total broodstock collection of 136 adults (66 natural origin and 60 hatchery origin; Table 10).

Pre-season run-escapement of Wenatchee spring Chinook to Tumwater Dam during 2019 is estimated at 1,599 spring Chinook, including 1,209 hatchery and 390 natural origin spring

Chinook (does not include age-3 males; Table 9). In-season estimates of natural-origin spring Chinook to Tumwater Dam will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%.

In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs, within the constraint of not collecting more the 33% of the natural origin spring Chinook. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

Table 9. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2019.

	Chiwawa Basin			Nason Cr. Basin			Wenatchee Basin to Tumwater Dam		
	Age-4	Age-5	Total	Age-4	Age-5	Total	Age-4	Age-5	Total
Estimated wild return	238	27	**265**	70	8	**78**	350	40	**390**
Estimated hatchery return	905	30	**935**	265	9	**274**	1,170	39	**1,209**
Total	1,143	57	**1,200**	335	17	**352**	**1,520**	**79**	**1,599**

Table 10. Number of broodstock *needed* for the combined Wenatchee spring Chinook production obligation of 367,969 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Chiwawa Conservation[4]	144,026	7/7M	31F/31M	**76**	Chiwawa Weir and Tumwater Dam[3]	2x2 factorial
Nason Conservation	125,000	8F/8M	26F/26M	**75[1]**	Tumwater Dam[3]	2x2 factorial
Nason Safety net	98,670	30F/30M[2]	0	**60**	Tumwater Dam	1:1
Total	**367,969**	**90**	**114**	**211[4]**		

[1] Includes ~10% additional NO fish for the Nason program to account for fish that may assign back to the White River spawning aggregate. No more than 52 NO fish will be retained for spawning.
[2] Chiwawa hatchery fish will only be collected to satisfy the Nason Cr. safety net program if in-season estimates of returning Nason conservation fish fall short of expectations.
[3] Collection of NO fish at Tumwater for the Chiwawa program will include previously PIT tagged adults (NO juveniles PIT tagged at the Chiwawa smolt trap) and/or excess NO adults/eggs/progeny originating from females with assignments >95% to the Chiwawa from the Nason conservation program.
[4] Total includes the 10% over-collection as part of the genetic assignment variance for the Nason conservation program.

Chiwawa River Conservation Program Broodstocking:

The 2019 pre-season forecast for NO adults back to the Chiwawa is well below the 2018 forecast (527 and 265 for 2018 and 2019 forecasts, respectively). It is under these circumstances that WDFW is proposing to maintain the number of bull trout encounters (and subsequent number of trappings days) to facilitate meeting the Chiwawa spring Chinook broodstock collection target as agreed to by the HCP HC. Consistent with the realized shortfall in NO broodstock in 2018, the 2019 operations plan seeks to maintain the number of bull trout encounters to about 93 (this theoretically increases the number of trapping days available from 15 to about 20). However, to minimize impacts to bull trout, operations will initially target the lower 15 day and 71 bull trout encounter levels. If additional NO brood collection is required operations may be extended to the 20 day and 93 bull trout encounter level. Should the higher level of trapping activity be required the USFWS will be notified in writing. Any further in-season modification of this plan would require concurrence on the part of the HC and the USFWS prior to implementation.

- Based upon estimates of returning previously PIT tagged NO fish to Tumwater Dam (Table 11), approximately 27 previously PIT-tagged NO spring Chinook from the Chiwawa River could be collected at TWD between June 1 and July 15, concurrent with Nason Creek brood stocking, adult management, RM&E, and the RRS Study.
- The balance adults needed to meet the Chiwawa Conservation program (up to ~76 total or ~38 females) would be collected at the Chiwawa Weir (HO adults will be collected at Tumwater Dam during the Nason broodstocking).

    - Weir operations would be on a 24 hour up/24 hour down schedule from about June 1 through August 15 (not to exceed 15 cumulative trapping days and/or 71 bull trout encounters or after notifying the USFWS, 20 cumulative trapping days and/or 93 bull trout encounters). Timing of trap operation would be based on NO fish passage at TWD and would use estimated travel times (derived from PIT tags) to the lower Chiwawa PIT tag antenna array.
    - Using the most recent 3-year redd count data (2014-2017; 2016 and 2018 survey data was not collected due to widlfires), the 10% threshold is 148 bull trout as determined by an average number of redds in the Chiwawa sub-basin of 739 (expands to 1,147 adults at a 1:1 sex ratio).
    - No more than 10 percent of the estimated mean number of adult bull trout in the Chiwawa Basin (using up to a rolling five year average derived from expanded redd counts) may be encountered during broodstock collection without concurrence from the USFWS.
    - To ensure the production target is met for the Chiwawa program, in the event that insufficient NO adults are collected for the conservation program (either through trap inefficiency or to not exceed 33% NO extraction), HO adults (presently estimated at 19% [N=14] of the total broodstock requirement, however may be

adjusted up or down depending on the run) would be collected at TWD to make up the shortfall (see Table 10) between June 1 and July 15.

- For additional assurance and to help reduce effort at the Chiwawa Weir, during broodstock collection for the Nason conservation program, any excess adults not genotyping to the White River will be retained for the Nason program and an equivalent number of adults that have assignment probabilities >95% for Chiwawa, will be transferred to the Chiwawa program.
- Historic and in-season data for NO spring Chinook timing to the lower Chiwawa array from TWD will be used to determine optimal dates for collection.
- Any bull trout that are caught at the Chiwawa trap will be immediately removed and released at a site ~10KM upstream of the weir to prevent fallback/impingement and to mitigate for potential delay. Handling and transport will be conducted by WDFW hatchery staff.
- If a bull trout is killed during trapping, despite implementing conservation measures, trapping activities will cease and not continue until additional measures to minimize risks to bull trout can be discussed with the USFWS.

Table 11. PIT tagged natural origin adults to Tumwater Dam for the most recent 5-years (2014-2018) with conversion rates from Bonneville Dam.

	Detections at Bonneville Dam		Detections at Tumwater Dam			
Return year	Nason	Chiwawa	Nason	Conversion rate	Chiwawa	Conversion rate
2014	6	66	1	0.167	29	0.439
2015	9	42	6	0.667	28	0.667
2016	8	34	8	1.000	24	0.706
2017	5	31	3	0.600	31	1.000
2018	1	27	1	1.000	26	0.963
Mean	5.8	40.0	3.8	0.687	27.6	0.755
Geomean	4.6	38.0	2.7	0.582	27.5	0.724

Nason Creek Conservation Program Broodstocking:

- Up to ~58 NO spring Chinook (to allow for up to 10 percent of White River NO fish estimated to be encountered at Tumwater Dam MSA; Table 10) would be collected at TWD between June 1 and July 15.
    - Only 52 NO adults (26 females) and 16 HO adults (8 females) will be retained to produce the 125K Nason Conservation program.
    - Collection of additional HO fish may occur in the event NO collection/retention falls short of expectation or would exceed 33% extraction.
    - Brood stock collection would run concurrent with adult management, RM&E, and the Spring Chinook Relative Reproductive Success Study. The GAPS microsatellite panel and existing GAPS plus WDFW spring Chinook Wenatchee

baseline will be used for genotyping and GSI analyses similar to methods used beginning in 2013.

- Decision Rules:
  - Any fish that assigns to the White River with greater than 90% surety will be released in the White River.
  - Unassigned fish (individuals that can't be assigned to the Wenatchee Population or Leavenworth NFH), will be released upstream of Tumwater Dam at the Alps or Swift Water rest stop.
  - In the event more fish assign to Nason or Chiwawa than are needed to meet the conservation program, the excess with the highest assignment probabilities (>95%) to the Chiwawa will be incorporated into the Chiwawa conservation program if needed or otherwise returned to the river upstream of Tumwater Dam.

Nason Creek Safety Net Program Broodstocking:

- At the current run forecast, up to ~60 HO spring Chinook adults (from conservation program [1st priority] – identified by snout wire + body wire) would be targeted at TWD (Table 10) between June 1 and July 15, concurrent with NO brood stock collection, adult management, RM&E, and the Spring Chinook Relative Reproductive Success (RRS) Study to meet a 98,670 smolt release.

<u>Steelhead</u>

The steelhead mitigation program in the Wenatchee Basin uses broodstock collected at Dryden and Tumwater dams located on the Wenatchee River. Per ESA section 10 Permit 18583 provisions, broodstock collection will target adults necessary to meet a natural origin – conservation (WxW) oriented program, not to exceed 33% of the natural origin steelhead return to the Wenatchee Basin and a hatchery origin (HxH) – safety net program. The conservation and safety net programs each make up approximately half of the 247,300 production obligation. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain a total of 136 mixed origin steelhead for broodstock for a smolt release objective of 247,300 smolts (Table 12). The 70 hatchery origin adults will be targeted at Dryden Dam and if necessary Tumwater dam. The 66 natural origin adults will be targeted for collection at Tumwater Dam. Collection will be proportional to return timing between 01 July and 14 November. Collection may also occur between 15 November and 5 December at both traps, concurrent with the Yakama Nation coho broodstock collection activities. Only adipose present coded wire tagged hatchery fish (or previously PIT tagged WxW hatchery progeny) will be retained for the safety net program unless low returns require use of safety net adults (adipose clipped) to meet the production obligation. Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and at Dryden Dam. In-season broodstock collection adjustments may be made based on this monitoring and evaluation.

To better ensure achieving the appropriate female equivalents for program production, the collection will include the use of ultrasonography to determine the sex of each fish retained for broodstock.

In the event steelhead collections fall substantially behind schedule, WDFW may initiate/coordinate adult steelhead collection in the mainstem Wenatchee River by hook and line. In addition to trapping and hook and line collection efforts, Tumwater and Dryden dams may be operated between February and early April the subsequent spring to supplement broodstock numbers if the fall trapping effort provides fewer than the required number of adults.

In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs, within the constraint of not collecting more the 33% of the natural origin steelhead. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

Table 12. Number of broodstock needed for the combined 2020 BY Wenatchee summer steelhead production obligation of 247,300 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Wenatchee Conservation[1]	123,650	0	33F/33M	**66**	TWD[3]/Dryden LBT-RBT[4]	2x2 factorial
Wenatchee Safety net[2]	123,650	35F/35M	0	**70**	Dryden LBT-RBT[4] /TWD[4]	1:1
Total	**247,300**	**70**	**70**	**136**		

[1] Broodstock collection for the conservation program will occur primarily at Tumwater Dam and will only fall back to Dryden Dam trapping facilities if a shortfall is expected.
[2] Broodstock collection for the safety net program will occur primarily at the Dryden Dam trapping facilities to minimize activities at TWD that could increase unintended delays on non-target fish. Collection at Tumwater Dam will only occur if shortfalls in broodstock are expected at Dryden Dam.
[3] TWD=Tumwater Dam.
[4] Dryden LBT-RBT= Dryden Dam left and right bank trapping facilities.

Summer/fall Chinook

Summer/fall Chinook mitigation programs in the Wenatchee River Basin utilize adult broodstock collections at Dryden and Tumwater dams, incubation/rearing at Eastbank Fish Hatchery (FH) and acclimation/release from the Dryden Acclimation Pond. The total production level target for BY 2019 is 500,001 smolts (181,816 GCPUD mitigation and 318,185 CCPUD mitigation).

The TAC 2019 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2014, 2015 and 2016 spawner escapement to the Wenatchee River indicate sufficient summer Chinook will likely return to the Wenatchee River to achieve full broodstock collection for the Wenatchee River summer Chinook supplementation program. Review of recent summer/fall Chinook run-timing past Dryden and Tumwater dams indicates that previous broodstock collection activities have omitted the early returning summer/fall Chinook, primarily due to limitations imposed by ESA Section 10 Permit 1347 to minimize impacts to listed spring Chinook. In an effort to incorporate broodstock that better represent the summer/fall Chinook run timing in the Wenatchee Basin, the broodstock collection will front-load the collection to account for the disproportionate collection timing. Approximately 43% of the summer/fall Chinook destined for the upper Basin (above Tumwater Dam) occurs prior to the end of the first week of July; therefore, the collection will provide 43% of the objective by the end of the first week of July. Weekly collection after the first week of July will be consistent with run timing of summer/fall Chinook during the remainder of the trapping period. With concurrence from NMFS, summer Chinook collections at Dryden Dam may begin up to one week earlier. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain up to 274 natural-origin, summer Chinook at Dryden and/or Tumwater dams, including 137 females (Table 13). To better ensure achieving the appropriate females for program production, the collection will implement the draft Production Management Plan, including ultrasonography to determine the sex of each fish retained for broodstock. Trapping at Dryden Dam may begin 24 June and terminate no later than 15 September and operate up to 7-days/week, 24-hours/day. Trapping at Tumwater Dam if needed may begin 15 July and terminate no later than 15 September and operate up to 48 hours per week for broodstock related activities.

In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of the broodstock necessary to backfill shortfalls.

Table 13. Number of broodstock needed for the combined 2019 BY Chelan and Grant PUD Wenatchee summer Chinook production obligations of 500,001 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Chelan PUD	318,185		87F/87M	**174**		
Grant PUD	181,816		50F/50M	**100**		
Total	**500,001**		**137F/137M**	**274**	Dryden LBT-RBT[1] /TWD[2]	1:1

[1] Dryden LBT-RBT= Dryden Dam left and right bank trapping facilities.
[2] TWD=Tumwater Dam.

Priest Rapids Fall Chinook

Collection of fall Chinook broodstock at Priest Rapids Hatchery (PRH) will generally begin in early September and continue through about mid-November. Juvenile release objectives specific to Grant PUD (5,599,504 sub-yearlings), and Federal (1,700,000 sub-yearlings at PRH + 3,500,000 smolts at Ringold Springs Hatchery – collection of broodstock for the federal programs are conditional upon having contracts in place with the ACOE), mitigation commitments. Biological assumptions are detailed in Appendix A. For the Ringold Springs production, adult collection, holding, spawning and incubation occurs at PRH until the eyed-egg stage. Eyed eggs are transferred to Bonneville Hatchery until they are transferred for spring acclimation and release at Ringold Springs.

For 2019 NO adults will be targeted through hook-and-line angling efforts in the Hanford Reach and the OLAFT to increase the proportion of natural origin adults in the broodstock to meet integration of the hatchery program will also be incorporated into the program. It is estimated that approximately 600 adults may be collected through the hook-and-line efforts and 650 adults will be targeted from the OLAFT. Close coordination between broodstock collections at the volunteer channel, the OLAFT and through hook-and-line efforts in the Hanford Reach will need to occur so over collection is minimized. Fish surplus to production needs will be culled at the earliest possible life-stage (e.g, prior to ponding, brood collected, brood spawned, eggs). Presumed NOR's collected and spawned from hook-and-line caught broodstock will be prioritized for PRH programs (i.e. Hanford Reach angler caught fish will be, held in a separate pond from volunteer collected fish, spawned first each week, and to the extent possible segregated and reserved for the GPUD program).

Grant PUD staff will work closely with WDFW hatchery and M&E staff to maintain separation of gametes/progeny of angling collected adults at spawning and through incubation/early rearing.

Based upon the biological assumptions in Appendix A, an estimated 4,651 females will need to be collected to meet the 10,799,054 smolts required to meet the current three up-river bright (URB) programs which rely on adults collected at the Priest Rapids Hatchery volunteer channel trap, the OLAFT, and hook-and-line efforts on the Hanford Reach (Table 14).

To increase the probability of incorporating a higher percentage of NOR's from the volunteer channel, adipose present, non-CWT males and females will be prioritized for retention and males older than 3 will be prioritized. In addition, preliminary information suggests that the pNORs is higher in the later part of the trapping period than the earlier period. As data become available, the PRCC-HSC may choose, in-season, to retain a disproportionately high number of broodstock from the latter half of the returns to the volunteer trap.

In-season data for fish age, size, and estimated fecundity may be used to adjust the number of broodstock collected to meet program production needs. Adjustments made to broodstock collection targets based on pre-spawn mortality exceeding current year assumptions will require review and concurrence on the additional number and composition of broodstock necessary to backfill shortfalls.

<u>Implementation Assumptions</u>

1) Broodstock may be collected at any or all of the following locations/means: hook-and-line angling (ABC) in the Hanford Reach (actual numbers collected are uncertain but will contribute to the overall brood program and pNOB), the Priest Rapids Hatchery volunteer channel trap, and the OLAFT.

2) Assumptions used to determine egg/adult needs is based upon current program performance metrics.

3) Broodstock retained from the volunteer channel will exclude to the degree possible, age-2 and 3 males (using length at age; i.e. retain males ≥ 75 cm) to address genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and also decrease the probability of using hatchery origin fish in the broodstock that are skewed towards earlier ages at maturity. Age-3 fish may be retained for broodstock if in-season run estimates suggest a shortage may occur.

4) Adipose present, non-CWT males and females will be prioritized for broodstock from the volunteer channel collected broodstock unless a shortage is expected.

5) Broodstock collected by hook-and-line will exclude age-2 to minimize genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and to ensure the highest proportion of NOR's in the collection.

6) All gametes of fish spawned from hook-and-line broodstocking efforts will be incorporated into the PRH based programs.

7) All juveniles released from PRH will, at a minimum, have a unique otolith mark so that returning adults can be identified.

8) Natural origin broodstock collection at the volunteer trap will be prioritized for the GPUD program by collecting fish when the probability of encountering natural origin fish is highest and balancing run-time representation.

Table 14. Number of broodstock needed for the combined Grant PUD and ACOE fall Chinook production obligations of 10,799,504 sub-yearling smolts at Priest Rapids and Ringold Springs hatcheries, collection location, and mating strategy in 2019.

Program	Production target	Number of Adults	**Total**	Collection location	Mating protocol
Grant PUD	5,599,504	2,427F/1,498M	**3,925**		
ACOE-PRH	1,700,000	737F/454M	**1,191**		
ACOE – Ringold[1]	3,500,000	1,534F/947M	**2,481**		
Total	**10,799,504**	**4,698F/2,899M**	**7,597**		

Collection location	Estimated number of adults		Total		
	Hatchery	Wild			
Priest Rapids Hatchery	**3,838F/2,155**	**222F/132M**	**6,347**	PRH volunteer trap	1:2
OLAFT	**103F/51M**	**331F/165M**	**650**		1:2, 1:4
ABC[2,3]	**19F/36M**	**185F/360M**	**600**	Hanford Reach	1:2, 1:4

Total	**3,960F/2,242M** (6,202; 90.4%)	**738F/657M** (729; 9.6%)	**7,597**

[1] As of brood year 2009, Priest Rapids Hatchery is taking sufficient eggs to meet the 3,500,000 sub-yearling smolt release at Ringold-Meseberg Hatchery funded by the ACOE – late incubation of this program occurs at Bonneville.
[2] Estimated number of fall Chinook females and males to be acquired from the OLAFT in 2019. F/M ratios were derived through run at large data. Estimates of H/W were derived through otolith results.
[3] ABC fish are adults collected from hook and line collection efforts on the Hanford Reach. Estimates of F/M were derived through 2012-2014 spawn numbers. Estimates of H/W were derived through otolith results from 2013 -2017.

Appendix A

2019 Biological Assumptions and estimated adult, green egg, and eyed egg targets for UCR spring, summer, and Fall Chinook and Summer Steelhead Hatchery Programs

2020	Okanogan WxW (CCT/GPUD)	Up to 100K [6]	Body and snout CWT[8]	Up to 20,000 PIT [,9]	Okanogan/Similkameen Omak, Salmon, Wildhorse Ck., other tribs. (TBD)	2021	5-8	Volitional from St. Mary's pond. The numbers going to Omak Creek and other tributaries will be determined by fall of 2020.

[1] WDFW would like to have a JFP discussion on an alternate tag (internal) for progeny of hatchery adults incorporated into the conservation program such that progeny of the wild parents can be prioritized. As such the minimum mark is identified with a TBD on an additional alternate mark.
[2] Externally marking of this group is presently funded by WDFW. Marking of this 1M fish is contingent on *US v. Oregon* Policy Committee approval for 2019.
[3] Presently all CWT's are applied to the snout.
[4] The Okanogan SPC program derives its juveniles from a 200K transfer of Methow SPC from WNFH as part of a reintroduction effort. Fish are released into the Okanogan Basin.
[5] The Chief Joe Hatchery SPC program presently receives surplus adults from the Leavenworth NFH as needed. Juveniles are released on station from CJH.
[6] Total Okanogan release not to exceed 100K + 10%.
[7] DPUD will tag 2,500 of the Twisp Only S1's and 2,500 of the Methow S1's. USFWS will tag 2,500 of the Methow S2's for release into the Twisp and 2,500 of the Methow S2's, will accompany the DPUD Methow S1's for an off station release.
[8] The Okanogan steelhead HGMP and NOAA's BiOp for the TRMP state that WxW progeny will receive a unique internal tag (CWT or PIT) and/or receive an alternative fin clip. At this time, CCT does not intend to use an alternative fin clip until/unless a high proportion of the released fish have WxW parents and there is an acceptable survival risk/benefit of the alternative fin clip.
[9] Total PIT tag release in the Okanogan 20,000
[10] Beginning with the 2017 brood, adult returns from the Nason conservation program will be utilized to meet the Nason safety net program and will receive a supplemental body tag (blank wire in the dorsal sinus) in addition to the adipose clip.
[11] With the recent detection of potential inbreeding depression effects in the Twisp conservation program, parties are continuing to develop a long term plan for the program. Once developed and agreed to, this table will be updated to reflect any changes.
[12] Winthrop NFH steelhead program produces 2-year (S2) smolts.
[13] For the 2020 brood, CWT placement will shift from the base of adipose fin to the dorsal sinus to evaluate if the adipose tagging location is responsible for spinal deformities and elevated mortality.

Appendix C

Return Year Adult Management Plans

At a gross scale, adult management plans will include all actions that may be taken within the current run year to address surplus hatchery fish (if any). At the time of submission for this document, spring Chinook will probably be the only group where a reasonable pre-season forecast may be available to lay out what the expected surplus is, how many can be expected to be removed through each action, etc. Preseason forecasts for steelhead will be available in September.

Wenatchee Spring Chinook

Pre-season estimates for age-4 and age-5 adults project a total of 1,599 (390 natural origin [24.4%] and 1,209 hatchery origin [75.6%]) spring Chinook back to Tumwater Dam in the Wenatchee Basin. Approximately 1,143 Chiwawa and 335 Nason spring Chinook are to reach Tumwater Dam in 2019, of which about 343 (22.1%) and 1,209 fish (77.9%) are expected to be natural and hatchery origin spring Chinook, respectively. The balance of about 47 natural origin spring Chinook expected back are destined to the remaining spawning aggregates (Table 1). In-season assessment of the magnitude and origin composition of the spring Chinook return above Tumwater Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18118 and 18121.

Table 1. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2019.

	Chiwawa Basin[1]			Nason Cr. Basin[1]			Wenatchee Basin to Tumwater Dam[2]		
	Age-4	Age-5	Total	Age-4	Age-5	Total	Age-4	Age-5	Total
Estimated wild return	238	27	**265**	70	8	**78**	350	40	**390**
Estimated hatchery return	905	30	**935**	265	9	**274**	1,170	39	**1,209**
Total	1,143	57	**1,200**	335	17	**352**	**1,520**	**79**	**1,599**

[1] Reflects NOR estimates to Tumwater Dam and has not been adjusted for pre-spawn mortality.
[2] Wenatchee Basin to Tumwater Dam total includes NORs to the White, Little Wenatchee, and Chiwawa rivers and Nason Creek.

Absent broodstock, conservation fisheries, or adult removal at Tumwater Dam (TWD), the expected number of age-4 and age-5 Hatchery Origin Returns (HOR) for the upper Wenatchee River Basin as a whole is estimated to be approximately 3.1 times the expected number of Natural Origin Returns (HORs; 3.5 times the number of NOR's in the Chiwawa River and in Nason Creek). The combined HO and NO returns will represent about 1.3 times the number of adults needed to meet the interim Chiwawa run escapement to TWD of 900 fish indicating a disproportionate number of hatchery origin spring Chinook will be on the spawning grounds in the fall of 2018 (Table 2). The combined HO and NO returns will represent about 70.4% of the number of adults needed to meet the interim Nason run escapement to TWD of 500 fish indicating a disproportionate number of hatchery origin spring Chinook may be on the spawning grounds in the fall of 2018 (Table 3).

Additional Adult Management

Adult management actions will be used to support achieving hatchery production levels and escapement/sliding-scale PNI targets identified in the Wenatchee Spring Chinook BiOp (2013; 2105) and Permits #18118, #18129 and #18121. Adult management removal targets identified in this document may be revised based on best available in-season run estimates.

2019 adult management actions are intended to provide for near 100% removal of age-3 hatchery males (jacks), and unknown hatchery origin adults (ad-/cwt-) during broodstock collection, run composition assessment, and the RSS. No additional adult removal is expected according to current models, Table 2. The return will be managed for escapement only unless actuals return are higher than the current forecast. In addition, approximately 90 HO and 114 NO adults will be removed between TWD and the Chiwawa Weir and retained for broodstock to support meeting the combined Grant and Chelan PUD Wenatchee spring Chinook obligation.

Table 2. Run escapement and spawning escapement of Chiwawa River hatchery and natural origin fish to Tumwater Dam and the Chiwawa River in 2019.

	To Tumwater Dam		To Chiwawa River		Adults surplused at TWD[3]	Total Chiwawa spawners[5]
	Wild	Hatchery	Wild[1,2]	Hatchery[2]		
Females[4]	146	636	87	331	0	**418**
Males[4]	119	299	64	145	0	**209**
Sub-total	265	935	151	476	0	**627**
Pre-spawn survival[6]			0.85	0.55		
Expected PNI						**0.52**
Expected pHOS						**0.76**

[1] Wild broodstock of 62 wild NO fish (38 females/38 males) for the Chiwawa conservation program have already been accounted for in this total as well as pre-spawn mortality.
[2] Adjusted for pre-spawn mortality and HO broodstock needs of 14 fish (7 females/7 males).
[3] Does not include age-3 hatchery males "jacks" removed during adult management activities at TWD.
[4] Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.
[5] This should result in approximately 418 redds in the Chiwawa Basin under the assumption that each female produces only one redd.
[6] Estimated survival from Tumwater to spawn.

Table 3. Run escapement and spawning escapement of Nason Creek hatchery and natural origin fish to Tumwater Dam and Nason Creek in 2018.

	To Tumwater Dam		To Nason Creek		Adults surplused at TWD[3]	Total Nason spawners[5]
	Wild	Hatchery	Wild[1,2]	Hatchery[2]		
Females[4]	43	186	53	97	0	**150**
Males[4]	35	88	41	43	0	**84**
Sub-total	78	274	94	140	0	**234**
Pre-spawn survival[6]			0.80	0.55		
Expected PNI						**0.56**
Expected pHOS						**0.60**

[1] Wild broodstock of 52 wild NO fish (26 females/26 males) for the Nason conservation program have already been accounted for in this total as well as pre-spawn mortality.
[2] Adjusted for pre-spawn mortality and HO broodstock needs of 76 fish (38 females/38 males).
[3] Does not include age-3 hatchery males "jacks" removed during adult management activities at TWD.
[4] Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.
[5] This should result in approximately 150 redds in Nason Creek under the assumption that each female produces only one redd.
[6] Estimated survival from Tumwater to spawn.

Methow Spring Chinook

Pre-season estimates project a total of 1,803 (785 natural origin [43.5%] and 1,018 hatchery origin [56.5%]) spring Chinook back to the Methow Basin. Of the 1,018 hatchery returns, about 431 are estimated to be from the conservation program with the balance of 587 from the WNFH safety net program (Table 5).

Table 5. Brood year 2014-2016 age class and origin run escapement projection for UCR spring Chinook at Wells Dam, 2019.

	Projected Escapement											
	Origin								**Total**			
	Hatchery				**Wild**				**Methow Basin**

%Total				7.9%				21.7%				13.9%
Winthrop (MetComp)	71	503	13	**587**					71	503	13	**587**
%Total				57.7%								32.6%
Total	135	849	34	**1,018**	31	584	170	**785**	166	1,433	204	**1,803**

Based on the current forecast, adult management to control MFH escapement, beyond removal of age-3 hatchery males during the course of broodstock collection and M&E, will not likely be needed. Active trapping and operation of the volunteer channel traps located at both the Methow Hatchery (MH) and Winthrop NFH (WNFH) will likely be needed to retain WNFH hatchery adults, and collect returning MFH adults for potential translocation into the spawning grounds.

Presently hatchery fish from MH are prioritized to: a) contribute to the supplementation of the natural populations (up to either the escapement objectives or PNI/pHOS goal), b) make up shortfalls in natural-origin brood for the MH conservation program, and c) to support the 400K safety-net program at WNFH. As such both hatcheries will operate volunteer hatchery ladders to support removal of excess safety-net and conservation fish (when needed). MH will operate its volunteer trap and will provide surplus hatchery adults (in excess to the MH and conservation needs) to WNFH to support the safety-net program, to support removal of excess safety-net and conservation fish, or retain adults to facilitate testing translocation of conservation fish to under-seeded spawning areas as approved by the HCP HC and PRCC HSC. The translocation of conservation program adults may be prioritized over their use as broodstock for the safety net program as long as both programs can meet full production and gene flow (pHOS/PNI) terms and conditions on the spawning grounds. The intention of adult translocation is to increase natural production which is the primary function of the Methow Hatchery. Any implementation of adult translocation as a strategy to increase the abundance of spawners in the natural environment will require the review and refinement (if necessary) of the approved 2017 Out-planting plan for implementation in 2019. Implementation of a Return Year 2019 Out-planting Plan should be supported by updated escapement estimates and outlines the targeted number, gender, out-planting location, and evaluation criteria. It is expected that the information provided in the 2019 BCP will serve as the starting point for development of the out-planting plan.

Specific actions are as follows:

Adult management actions will be used to support achieving hatchery production levels and escapement/sliding-scale PNI targets identified in the Methow Spring Chinook BiOp (2017) and Permits #18925, #18927 and #20533. Adult management removal targets identified in this document may be revised based on best available in-season run estimates.

Twisp River Spring Chinook: spring Chinook in the Twisp River will be managed separately from the rest of the basin.

a. Adipose-clipped fish encountered at the Twisp Weir will be removed (putative WNFH returns or strays from outside of the basin).
b. Age-3 hatchery males will be removed and euthanized or transported to WNFH for surplusing unless there is a broodstock shortage – in that case age-3 males may be used as brood on a very limited basis (up to 2 Age-3 fish may be used if necessary, but up to one is preferred, only of necessary).
c. Adult management will be performed to maintain pHOS ≤0.50. pNOB will be >0.50 and may be allowed to fluctuate between 0.50 and 1.0 in order to achieve a pHOS ≤0.50.

d. Wild fish will be collected as broodstock – up to ~18 individuals, but not to exceed 33% of the wild run. Hatchery fish may be collected as broodstock, dependent on collection success of wild fish and provided that Twisp-program pNOB may not be less than 0.50.
e. The Twisp Weir will be fished for the duration of the broodstock collection, only, in 2019. Adult management activities will be incidental to broodstock collection. Once broodstock collection is completed, the weir will be opened to fish passage to limit delay/trapping effects on bull trout. During broodstock collection, the weir will be fished from 6:00 AM to 9:00 PM on a daily basis. Deviation from this schedule may be implemented based on the run size and catch efficiency for broodstock.

Methow River (MFH and WNFH) and Chewuch River Spring Chinook (MetComp):

a. Stock assessment will be performed at Wells Dam during the spring Chinook broodstock collection. This information on stock, hatchery:wild, and male:female composition in conjunction with fish counts at Wells Dam will be used to adjust in-season adult management targets.
b. MetComp returns will be managed by removing volunteers at WNFH and Methow Hatchery using the outfall traps at these facilities.
    i. All hatchery-origin age-3 males will be removed
        1. Gender identified by ultrasound.
    ii. The Methow FH and Winthrop NFH volunteer traps will be fished continuously (24 h per day/7 d per week) throughout the run and fish removed at least once daily (depending on specific facility limitations), or as often as needed when fish are present. Adjustments to the operation of the trapping facilities will be made based upon capture/extraction rates as well as bull trout encounters and take limitations.
    iii. Trapping may cease at Methow Hatchery if:
        1. Removal of MFH and WNFH origin adults meets the broodstock and/or adult management targets established (in this document and as adjusted in-season, and/or through the development of an approved Out-planting plan), or
        2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.
    iv. Trapping may cease at Winthrop NFH if:
        1. Removal of WNFH and MFH origin adults meets the broodstock and/or adult management targets established (in this document and as adjusted in-season, and/or through the development of an approved Out-planting plan), or
        2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.
    v. All adipose clipped returns encountered at WNFH and MFH volunteer traps will be removed.

1. Returns to WNFH will be retained at WNFH for broodstock (WNFH safety net and Okanogan 10(j) programs) or surplusing.
2. Returns to MFH will be transferred to WNFH for broodstock (WNFH safety net and Okanogan 10(j) programs) or surplusing.

vi. Conservation program returns may also be transported to specific reaches of the Methow and/or Chewuch Rivers (or other locations as determined by the HC/HSC) to meet the minimum spawning escapement objective or to experimentally augment spawner distribution (such an action will require an approved study or implementation plan by the HCP HC and PRCC HSC, and be permissible under current ESA permits).

Based on the preseason forecast for wild and hatchery spring Chinook to the Methow Basin, once NO broodstock requirements are fulfilled and accounting for an estimated prespawn mortality for NO fish of 50% (42% for HO fish), there will be approximately 329 NO spawners. Based upon the sliding PNI scale for NO run sizes >300 fish, the initial goal for 2019 will be to manage for a minimum spawning escapement of 548 spawners; to achieve this, based on the current forecast, the collection and translocation of hatchery fish will likely be needed (Table 6). This will require an approved out-planting plan for 2019 (using the approved 2017 plan as a starting point) that balances the current and out-year effects to PNI with the need to supplement natural production. Further, the 400K WNFH (in addition to the 200K 10j program) safety net program would need to utilize WNFH returning adults for some or all of its broodstock. Up to 100 % of the MFH HO returns collected at the outfalls would be translocated to the spawning grounds, any MFH HO returns retained may be used for broodstock for the WNFH safety net program to meet PNI requirements. It is expected that in the course of developing an out-planting plan for 2019, the parties will utilize the information provided in Table 6 as well as develop modeling scenarios to anticipate how various out-planting and broodstock collection strategies may impact natural production and PNI (using the multi-pop PNI calculation) in the current and out years.

Table 6. Calculated targets and projected adult management expectations for Methow spring Chinook in 2019 based on current run forecast.

Wild Spawning Escapement[1]		pNOB[2]	pHOS	PNI [3]	Hatchery Spawners[1,4]	Hatchery surplus[4]	Hatchery Broodstock (WNFH + 10j)	Proportion of Hatchery Fish to Remove	Total spawning escapement
Twisp	76	0.96	0.29	0.77	31	0 MH		0	107
Methow/Chewuch	253	0.89	0.34	0.72	132	56 WNFH[5]	472 (316 WH+156 WH)	0	441
Total	329	0.93	0.33	0.74	163	56	472 (316 WH+156 WH)	0	548

[1] Adjusted for prespawn mortality.
[2] pNOB of conservation program only averaged for BY14, 15, and 16. pNOB target for BY19 is 1.0 for both programs.
[3] Because of the uncertainty around run forecasts, PNI was provisionally estimated using the PNI=pNOB/(pNOB+pHOS) equation.
[4] Assumes a 90% conversion of hatchery fish to hatchery outfalls. Value already considers hatchery adults needed to meet WNFH and Okanogan 10(j) production components.
5 If the estimated 56 surplus WNFH are allowed (or assumed) to be on the spawning grounds, PNI would drop to 0.67.

In-season assessment of the abundance and origin composition of the spring Chinook return above Wells Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18925, 18927, and 20533.

Methow Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Methow Basin should the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT) occur, removal of surplus adult steelhead may occur at the Twisp Weir to meet an overall pHOS = 0.25 with 0.20 allocated to the Twisp Conservation program returns (the exception to this would be if a higher pHOS is still needed to wrap up the remaining time series on the Relative Reproductive Success Study as approved),the Wells Hatchery Volunteer Channel, volunteer returns to the Methow Hatchery and Winthrop NFH, during broodstock collection efforts (including angling), or in combination with a conservation fishery, consistent with ESA authorizations.

Okanogan Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Okanogan Basin should the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT) occur, removal of surplus adult steelhead may utilize a conservation fishery or in combination with removal through spring Okanogan tributary weir operations, consistent with ESA authorizations.

Wenatchee Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Wenatchee Basin should the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT) occur, removal of surplus adult steelhead may utilize a conservation fishery or in combination with removal through spring Wenatchee tributary weir operations, consistent with ESA authorizations.

Adult management plans, if needed, will be finalized then and appended to this document.

Priest Rapids Fall Chinook

The Joint Fisheries Parties have an elevated interest in ensuring any surplus adults back to Priest Rapids Hatchery are made available to back fill anticipated shortfalls in other Columbia River fall Chinook programs given the low 2019 return forecast. As no specific action plan has yet been discussed or developed by the parties, this space is reserved for those details to be inserted at a later date.

Appendix D

Site Specific Trapping Operation Plans

Tumwater Dam

For 2019, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for Tumwater Dam is summarized in Table 1):

1) **Real-time monitoring and trap operations:** The PIT tag antennae arrays at the entrance (low and high water entrances; A4 and A5) and at weir 18 (A1) within the Tumwater Dam ladder will be monitored by WDFW and Chelan PUD throughout all trapping activities described in this plan. Detections of previously PIT tagged fish will be evaluated to determine the median passage time of fish between first detection at the ladder entrances and last detection weir 18. Median passage estimates will be updated with every 10 PIT-tagged fish detected at the ladder entrance. If the median passage time is greater than 48 hours, trapping will cease and fish will be allowed to exit via the ladder (i.e., bypass the trap). If trapping has been stopped, PIT tag passage monitoring will continue and trapping will resume if and when the median passage time is less than 24 hours. In summary, real-time PIT tag monitoring will occur both when the trap is operational and when fish are bypassed. This will provide an opportunity to evaluate trapping effects versus baseline passage rates through the ladder for future operations.

2) **Enhanced effort for Tumwater trapping operations from June 1 and July 15**: The Tumwater trap will be operated in an active-manned trapping condition (the ladder bypass will not be used however, fish may still ascend the denil [steep pass] unimpeded). The trap will be checked a minimum of 1x per day. More frequent trap checks will be made as fish numbers increase. Between June 16 and July 15 the Tumwater trap will be actively manned 24 hours/day 7 days/week utilizing two- three person crews (two people will sample fish and the third will maintain operation of the steep pass so that it will not be closed to passage). This represents an additional person to keep the denil operating constantly. If during this period staff are not available (due to logistical, funding, or other issues) to keep the denil operating continuously, the trap will be opened to allow for nighttime passage (this is in addition to passage required under a detected delay event).

3) **Enhanced effort and limited Tumwater trapping operations from July 16 to August 31**: The trap will be operated 3 days/week for up to 16 hours/day (not to exceed 48 hours per week) to support broodstock collection activities for summer Chinook and sockeye run composition sampling (CRITFC) and sockeye spawner escapement PIT tagging. Video enumeration and full passage will occur when trapping is not occurring.

4) **Planned Tumwater trapping operations from September 1 until mid-December:** To facilitate lamprey passage and meet coho and steelhead broodstocking and steelhead adult management needs, the trap is being proposed to operate up to 16 hours per day from 6AM to 10PM 7days/week manned or unmanned active trapping. The trap will be open for lamprey passage between the hours of 10PM and 6AM. During this time period

bull trout are rare and spring Chinook are not present at Tumwater. For this trapping period, real-time monitoring will be implemented with video enumeration when opened.

5) **Operations at Tumwater from mid-December until about mid-February:** During this period the trapping facility is not operated due to having been winterized. Only video enumeration and full passage are available during this period.

6) **Planned Tumwater trapping operations from mid-February through May:** The trap may return to a 24 hours/7days/week manned or unmanned active trapping for adult steelhead management and/or broodstock collection as needed. Beginning on or about May 1, limited spring Chinook broodstocking, run comp sampling, etc. may also occur. For this trapping period, real-time monitoring will continue to be implemented.

7) **Limitation in staffing or other unforeseen problems:** If WDFW staff are not available to operate the trapping facility (according to this plan) for any reason, then full passage will be allowed (fish will be allowed to bypass the trap and exit the ladder directly), until staff are able to return.

8) **Unforeseen scenarios and in season observations**: If during the trapping period, observations from field staff warrant reconsideration of any part of the plan as described above, WDFW and Chelan PUD will alert the Hatchery Committee and work cooperatively with the Services to determine whether changes are needed to further minimize incidental take or otherwise ensure that take is maintained at the manner and extent previously approved by the Services.

Table 1. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and reproductive success activities anticipated to be conducted at Tumwater Dam in 2019. Blue denotes steelhead, brown spring Chinook, orange sockeye, pink summer Chinook, and green Coho.

Su. Chin BS collection[10]							1 Jul		15 Sep			
Coho BS collection[11]									1 Sep		30 Nov	

[1] Adult management of the 2019 brood will end in June 2019. However it is anticipated that adult management will occur for the 2020 brood (if needed) beginning 1 September or earlier if conducted in conjunction with broodstock collection activities at Tumwater Dam for other species.

[2] Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities.
[3] SHD spawner composition tagging at Tumwater Dam will run concurrent with SHD adult management and other (broodstock) activities at Tumwater Dam.
[4] The spring Chinook RSS will run from 1 May through about 15 July or at such time or at such time the sockeye return develops at Tumwater Dam.
[5] Spring Chinook run composition sampling will run concurrent with the RSS.
[6] Spring Chinook pHOS management will end in July consistent with the arrival of the sockeye return and run concurrent with RSS activities.
[7] Removal of unknown hatchery origin spring Chinook strays at Tumwater Dam will run concurrent with the RSS.
[8] Sockeye run composition sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for run composition sampling will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.
[9] Sockeye spawner escapement sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for spawner escapement tagging will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.
[10] Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Tumwater Dam for summer Chinook broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[11] Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Tumwater Dam for Coho broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 7 of each year but typically ceases by the end of November.

Dryden Dam

For 2019, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for the right and left bank Dryden Dam traps is summarized in Table 2):

The Dryden Dam left and right bank trapping facilities will operate up to 7 days per week, 24 hours per day beginning June 24 and continue until as late as November 15. Both traps, if operated, will do so on concurrent days and will be checked and cleared every 24 hours, or sooner if it appears that run contribution to the facilities exceeds reasonable limits for adult holding.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 2. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Dryden Dam trapping facilities in 2019. Blue denotes steelhead, pink summer Chinook, and green Coho.

Activity	Month

Su. Chin BS collection[3]							1 Jul		15 Sep			
Coho BS collection[4]									1 Sep		30Nov	

[1] Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities. In the event steelhead brood cannot be met by Nov 14 and the YN coho program does not need to operate the trap(s), steelhead brood collection may continue independently through Dec 5.
[2] SHD spawner composition tagging at Dryden Dam will run concurrent with other (broodstock or M&E) activities at Dryden Dam.
[3] Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Dryden Dam for summer Chinook broodstock will follow an up to 7d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[4] Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Dryden Dam for Coho broodstock will follow an up to 7d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 5 of each year but typically ceases by the end of November.

Chiwawa Weir

For 2019, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for the Chiwawa Weir is summarized in Table 3):

Weir operations will be on a 24 hour up/24 hour down schedule from about June 1 through August 15 (not to exceed 20 cumulative trapping days and/or 93 bull trout encounters). Timing of trap operation would be based on NO fish passage at TWD and would use estimated travel times (derived from PIT tags) to the lower Chiwawa PIT tag antenna array.

Table 3. Summary of broodstock collection activities anticipated to be conducted at the Chiwawa Weir in 2019. Brown denotes spring Chinook.

Sp Chin BS collection						1 June		15 Aug				

Wells Dam Ladder and Hatchery Volunteer Traps

For 2019, WDFW and Douglas PUD propose the following plan (activities by month for the Wells Dam East/West ladder and Wells FH volunteer traps are summarized in Table 4):

1). **East Ladder Trap:**

The East ladder trap will only be operated as needed to meet broodstock collection objectives and other management activities if they cannot be adequately fulfilled through the West ladder and Wells FH volunteer trap operations or if the use of either the West ladder or volunteer traps is precluded for some reason.

If the East ladder trap is used, it may begin as early as May 1 and, with two exceptions, will operate under a maximum 3-day per week/16 hours per day or 48 cumulative hours per week and will run concurrent with any trapping activities occurring at the West ladder trap. The first exception to the above is that for spring Chinook between May 1 and June 20, the trap may operate a maximum of 7-days per week/16 hours per day and will run concurrent with any trapping activities occurring at the West ladder trap. The second exception is for coho trapping after September 26. Anticipated trap operation is not expected to go beyond November 15.

For coho trapping, the East ladder trap may be operated, concurrent with the West ladder trap, 5 days per week/ 9 hours per day September 27 through October 9, and 7 days per week/16 hours per day beginning October 10. Trap operators will bypass Chinook, steelhead, and sockeye during coho trapping. Anticipated trap operation is not expected to go beyond November 15.

The CRITFC may also trap sockeye at Wells Dam for tagging and stock assessment. Their request for trapping in 2019 did not specify trapping details other than timing (late June through early August), but their preference in past years has been to use the East ladder.

If daily river temperatures meet or exceed 21º C (69.8º F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

2). **West Ladder Trap:**

The West ladder may begin as early as May 1 for spring Chinook broodstock collection and, with two exceptions, will operate under a maximum 3-day per week/16 hours per day or 48 cumulative hours per week. The first exception to the above is that for spring Chinook between

May 1 and June 20, the trap may operate under a maximum 7-days per week/16 hours per day and will run concurrent with any trapping activities occurring at the East ladder trap. The second exception is for coho trapping after September 26. Anticipated trap operation is not expected to go beyond November 15.

For coho trapping, the West ladder trap may be operated 5 days per week/ 9 hours per day September 27 through October 9, and 7 days per week/16 hours per day beginning October 10. Trap operators will bypass Chinook, steelhead, and sockeye during coho trapping. Anticipated trap operation is not expected to go beyond November 15.

The CRITFC may also trap sockeye at Wells Dam for tagging and stock assessment and may use the west ladder; however, their preference in past years has been to use the East ladder. CRITFC has proposed trapping from late June through early August.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

3). **Wells FH Volunteer Trap:** The Wells FH volunteer trap may begin as early as July 1 for summer Chinook broodstock collection and operate through mid-June of the following year for steelhead broodstock collection and adult management if needed. The trap may operate up to seven days per week/24 hours per day to facilitate broodstock collection and adult management actions.

If water temperatures in the trapping facility meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 4. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Wells Dam in 2019. Blue = steelhead, brown = spring Chinook, pink = summer Chinook, orange = sockeye, and green = Coho.

Su. Chin Surplussing	1 Jul	30 Oct

[1] Summer steelhead broodstock collection will be prioritized at West ladder and volunteer traps. However if broodstock objectives cannot be met at either of those two locations then trapping may occur at the East ladder concurrent with other activities.
[2] SHD spawner composition tagging at Wells Dam will run concurrent with other (broodstock or M&E) activities at Wells Dam.
[3] Summer Chinook broodstock collection for the Methow (Carlton) program will be prioritized at the West ladder trap. However if broodstock objectives cannot be met at the West ladder then trapping may occur at the East ladder. Trapping at the west and/or East ladders for summer Chinook broodstock will follow an up to 3d/week 16hr/day (48 cumulative hours) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[4] CRITFC trapping of sockeye for stock assessment and tagging typically begins the last week of June and extends through the third week of August, following an up to 3d/week 16hr/day (48 cumulative hours) coordinated with WDFW spring or summer Chinook and steelhead broodstock collection and stock assessment trapping, preferring to trap on the East ladder.
[5] Coho trapping may be conducted at both East and/or West ladders. Trapping at Wells Dam ladder traps for Coho broodstock prior to September 27, will follow up to 3d/week 16hr/day (48 cumulative hours) coordinated with WDFW steelhead broodstock collection and stock assessment trapping; from September 27 through October 9, an up to 5d/week 9hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities, and 7 days per week/16 hours per day beginning October 10. Trapping at the Wells Dam ladder will cease no later than November 15.
[6] Adult management of the 2019 brood will end in June 2019. However it is anticipated that adult management will occur for the 2020 brood beginning 1 September 2019 or earlier if conducted in conjunction with broodstock collection activities at the Wells Hatchery volunteer channel for other species.
[7] Summer Chinook broodstock collection for the Wells Hatchery programs will be prioritized at the Wells Hatchery volunteer trap. Trapping at the volunteer channel may occur up to 7 days per week, 24 hours per day and may include broodstock collection and/or adult management.

Methow Hatchery Volunteer and Twisp Weir Traps

For 2019, WDFW and Douglas PUD propose the following plan (A summary of activities by month for Methow Hatchery volunteer trap and the Twisp Weir is summarized in Table 4):

Methow Hatchery Volunteer Trap

The Methow Hatchery volunteer trap may be operated for spring Chinook as early as May 1 through August 31 for broodstock collection and gene flow management. The trap may be operated from approximately March 1 through June 1 for steelhead broodstock collection and gene flow management. In all cases, the trap may be operated 24 hours a day, seven days a week. The trap will be checked at least once every 24 hours, but will be checked two or more times a day when fish are abundant. Trap operations will be adjusted if bull trout captures approach ESA take limits. Trapping operations will be halted prior to exceeding ESA take levels for any ESA listed species.

If daily river temperatures meet or exceed 21º C (69.8º F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Twisp Weir

1) **General Weir Operating Parameters:**
    a. Weir fished from ice out in late February/early March through mid-August.
    b. Steelhead trapping occurs from late February/early March through June 1.
    c. Spring Chinook Trapping occurs from June 1 until broodstock and adult management targets are achieved (usually prior to mid-August).
    d. The height of the weir panels is hydraulically controlled and panels are set at the water surface level when the weir is fishing to allow downstream migrating steelhead, spring Chinook, and bull trout to safely and effectively pass the weir.
    e. Weir is tended by DPUD or WDFW personnel whenever the trap is operated. WDFW is contracted by Douglas PUD under the HCP Monitoring and Evaluation Plan to monitor the trap.
    f. Operation of the weir under the ESA is currently authorized by Section 10 Permits 18925 and 1395 (1395 permit extended by NMFS on September 20, 2013).
    g. Real-time monitoring and trap operations: Throughout all trapping activities described in this plan, PIT tag interrogation locations WEL and WEA (Wells Dam), WEH (Wells Hatchery), LMR (Lower Methow River) and TWR (Twisp River) will be monitored by WDFW and DCPUD staff for detections of previously PIT tagged steelhead, spring Chinook, and bull trout. Detections at Wells Dam are nearly 100% efficient. However, detections at LMR and TWR during the higher flows, particularly when spring Chinook and bull trout are migrating, may be less than 20% efficient (comparing fall downstream movements to upstream movements). Data will be examined on a yearly basis to determine if there are peak periods when bull trout are most likely to pass the weir.
    h. When the weir is not fishing, the weir panels will be lowered to the stream bottom, or the traps will be opened to passage, or both. If only the weir panels are lowered the entrances to the traps will be closed.
    i. Limitation in staffing or other unforeseen problems: If staff are not available to staff the trapping facility (according to this plan) for any reason, or the trap will not be checked within 24 hours, then full passage will be allowed by lowering the weir panels or opening the traps or both, dependent on flow conditions until staff are able to return.
    j. Unforeseen scenarios and in-season observations: If during the trapping period, observations from field staff warrant reconsideration of any part of the plan as described above, WDFW and the District will alert the National Marine Fisheries Service, HCP Hatchery Committee, and/or the USFWS, as appropriate, and work cooperatively with these parties to minimize incidental take or otherwise ensure that take is maintained at the manner and extent previously approved by the USFWS.
    k. Trapping effort monitoring: Trapping effort in the form of daily trap operation time will be recorded by trap operators. Trapping effort will be used in subsequent years to refine this plan.

l. Nocturnal vs diurnal use: Species composition during trapping hours will be recorded to document times of day when various species are trapped.
m. Trapping will be suspended prior to exceeding the take limits specified by USFWS for bull trout and by NMFS for summer steelhead and spring Chinook.
n. Broodstock collection target numbers are established annually prior to trapping based on predicted age composition, fecundity, and survival of broodstock and rearing in-hatchery.
o. This Plan does not limit other ESA Permit (1395 and 18925, Wells Bull Trout Biological Opinion) conditions that also apply under this plan.

2) Late February/Early March through June 1 Operations:

a. Weir begins fishing in late February or early March as environmental conditions allow.
b. The weir will be fished constantly during this time to trap steelhead, as conditions allow. The weir will be tended by WDFW personnel at least once daily, but twice daily or more when fish are present. An attempt will be made to capture all adult steelhead during this time period:
    i. Steelhead are trapped during this period for Twisp River broodstock collection for the Douglas PUD Twisp Steelhead Conservation Program (N~12-26).
    ii. Steelhead are trapped for population census data collection and for a relative reproductive success study of hatchery and wild steelhead required of Douglas PUD under the Wells HCP.
    iii. Steelhead are trapped to control the relative abundance of hatchery and wild steelhead adults upstream of Twisp Weir. Steelhead removed via adult management may be used as broodstock for other Douglas PUD and WNFH programs.
c. Bull trout have not been observed or trapped at the Twisp Weir prior to June 5^{th}.
d. No more than 118 adult and 50 sub-adult bull trout (also includes 19 juveniles) handled in the entire trapping season. Trapping would be suspended with one lethal take of any size bull trout.
e. High flows that may occur during the steelhead trapping season can significantly limit the efficiency of the weir or prevent fishing the weir. In these cases, the weir panels are lowered or over-topped by the water and the traps are opened for passage. During such flow episodes that prevent trapping, the weir and trap boxes are fully passable to all species.

3) June 1 through August Operations:

a. The weir will be fished selectively during this time period to trap spring Chinook broodstock. Normally the weir will be fished daily from 6:00 AM until 9:00 PM, but overnight trapping may be used if greater trapping effort is needed to collect spring Chinook broodstock. When the weir is not fishing, the weir panels will be lowered and/or the traps will be opened to allow passage.
b. Trapping effort will be based on meeting the spring Chinook broodstock collection target for adult spring Chinook of natural origin. In-season information derived from sampling and counts at Wells Dam and PIT tag detections at in-river

arrays will inform trapping operations in order to target spring Chinook while reducing effort when spring Chinook are not likely to be available.

c. Trapping will not necessarily occur every day or for 24 consecutive hours per day, dependent on efficiency of trapping operation in obtaining broodstock. Fine-scale scheduling of trap operations will be determined on a day-to-day basis.
d. No more than 118 adult and 50 sub-adult bull trout (also includes 19 juveniles) handled in the entire trapping season. Trapping would be suspended with one lethal take of any size bull trout.
e. Trapping will be suspended when the broodstock target is met. When the weir is not fishing the traps will be opened to allow passage and the weir panels will be lowered. The traps will be removed from the river in mid- to late August.
f. High flows significantly limit the efficiency of the weir or prevent fishing the weir entirely. In these cases, the weir panels are lowered and the traps are opened for passage. During high flow episodes that prevent trapping the weir is fully passable to all species.

Table 4. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Methow Hatchery and the Twisp Weir in 2019. Blue denotes steelhead and brown denotes spring Chinook.

Sp. Chinook pHOS mgt.						1 June		22 Aug				

[1] Specific details on how operation of the Methow Hatchery volunteer trap will work for SHD adult management are still being worked out at this time.
[2] Adult management for spring Chinook at the Methow Hatchery volunteer trap will run concurrent with broodstock collection.
[3] Specific details on how operation of the Twisp Weir will work for 2019 to include the steelhead RSS, broodstock collection, and adult management and spring Chinook broodstock collection and adult management is still being worked out at this time.

Priest Rapids Dam Off-Ladder-Adult-Fish-Trap (OLAFT)

Table 5. Summary of broodstock collection, VSP monitoring, and/or run composition sampling activities anticipated to be conducted at the Priest Rapids Dam Off-Ladder-Adult-Fish-Trap (OLAFT) in 2019. Blue denotes steelhead, purple fall Chinook, and orange sockeye. All users of the OLAFT must have a signed Facility Use Agreement with GPUD.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
SHD VSP Monitoring[1]							1 Jul				15 Nov	
Fall Chinook Run Comp.[2]									1 Sep		15 Nov	
Sockeye BS Collection[3]						22 Jun	10 Jul					

[1] Steelhead VSP monitoring, if it occurs in 2019, will target up to 15% of the annual return over Priest Rapids Dam. Presently that requires operation of the OLAFT up to 3 days/ week, 8 hours per day. The trap is opened to passage each night.
[2] Fall Chinook run composition runs concurrent with SHD VSP monitoring.
[3] Sockeye broodstock collection to support YN reintroduction efforts in the Yakima is based upon abundance based sliding scale. Depending on the strength of the return and allowable allocation, the trap may be operated up to 5 days per week, 8 hours per day beginning about 22 June and running through about 10 July. The trap is opened to passage each night.

Appendix G

DRAFT
Hatchery Production Management Plan

The following management plan is intended to provide life-stage-appropriate management options for Upper Columbia River (UCR) PUD salmon and steelhead mitigation programs. Consistent, significant over-production or under-production risks the PUD's not meeting the production objectives required by FERC and overages in excess of 110% of program release goals violates the terms and conditions set forth for the implementation of programs under ESA and poses potentially significant ecological risks to natural origin salmon communities.

Under RCW 77.95.210 (Appendix A) as established by House Bill 1286, the Washington Department of Fish and Wildlife has limited latitude in disposing of salmon and steelhead eggs/fry/fish. While this RCW speaks more specifically to the sale of fish and/or eggs, WDFW takes a broader application of this statute to include any surplus fish and/or eggs irrespective of being sold or transferred.

We propose implementing specific measures during the different life-history stages to both improve the accuracy of production levels and make adjustments if over-production occurs. These measures include (1) Improved Fecundity Estimates, (2) Adult Collection Adjustments, (3) Within-Hatchery Program Adjustments, and (4) Culling at the earliest life-stage.

<u>Improved Fecundity Estimates</u>

A) Develop broodstock collection protocols based upon the most recent 5-year mean in-hatchery performance values for female to spawn, fecundity, green egg to eye, and green egg to release.

B) Use portable ultrasound units to confirm gender of broodstock collected (broodstock collection protocols assume a 1:1 male-to-female ratio). Ultrasonography, when used by properly trained staff will ensure the 1:1 assumption is met (or that the female equivalents needed to meet production objective are collected). Spawning matrices can be developed such that if broodstock for any given program are male limited, sufficient gametes are available to spawn with the females.

<u>Adult Collection Adjustments</u>

C) Make in-season adjustments to adult collections based upon a fecundity-at-length regression model for each population/program and origin composition need (hatchery/wild). This method is intended to make in-season allowances for the age structure of the return (i.e. age-5 fish are larger and therefore more fecund than age-4 fish), but will also make allowances for age-4 fish that experienced more growth through better ocean conditions compared to an age-5 fish that reared in poorer ocean conditions.

<u>Within-Hatchery Program Adjustments</u>

D) At the eyed egg inventory (first trued inventory), after adjustments have been made for culling to meet BKD management objectives, the over production will be managed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:
- Voluntary cooperative salmon culture programs under the supervision of the department under chapter 77.100 RCW;
- Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
- Salmon culture programs requested by lead entities and approved by the salmon funding recovery board under chapter 77.85 RCW;
- Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter 39.34 RCW; and
- Governmental hatcheries in Washington, Oregon, and Idaho; or
- Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
- Distribution to approved organizations/projects for research.

E) At tagging (second inventory correction) fish will be tagged up to 110% of production level at that life stage. If the balance of the population combined with the tagged population amounts to more than 110% of the total release number allowed by Section 10 permits then the excess will be distributed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:
- Voluntary cooperative salmon culture programs under the supervision of the department under chapter 77.100 RCW;
- Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
- Salmon culture programs requested by lead entities and approved by the salmon recovery funding board under chapter 77.85 RCW;
- Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter 39.34 RCW; and
- Transfer to another resource manager program such as CCT, YN, or USFWS program;
- Governmental hatcheries in Washington, Oregon, and Idaho;
- Placement of fish into a resident fishery (lake) zone, provided disease risks are within acceptable guidelines; or
- Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
- Distribution to approved organizations/projects for research.

F) In the event that a production overage occurs after the above actions have been implemented or considered, and deemed non-viable for fish health reasons in accordance with agency aquaculture disease control regulations (i.e. either a pathogen is detected in a population that may pose jeopardy to the remaining population or other programs if retained or could introduce a pathogen to a watershed where it had not previously been detected) then culling of those fish may be considered.

All, provisions, distributions, or transfers shall be consistent with the department's egg transfer and aquaculture disease control regulations as now existing or hereafter amended. Prior to department determination that eggs of a salmon stock are surplus and available for sale, the department shall assess the productivity of each watershed that is suitable for receiving eggs.

Species/Program Specific Juvenile Surplussing Protocols:

Surplus UCR Juvenile Steelhead Management

Above Wells Programs:

In the event excess HxH juveniles are produced from over-collection efforts to support the Methow Safety-Net and /or Okanogan programs which rely on spring adult collections, the parties agree that distribution of juveniles will follow the following priority matrix:

1. Progeny transferred to the Columbia Safety-Net program provided fish health and/or marking requirements for the program can be met.

2. Used to support shortfalls in the WNFH production obligation provided fish health and/or marking requirements for the program can be met and provided basin wide pHOS/PNI allow for a decrease in program pNOB.

3. Used to support shortfalls in the Ringold SHD program provided fish health and/or marking requirements for the program can be met.

4. Out-planted to landlocked lakes within Okanogan County and/or Colville Reservation provided fish health requirements can be met or provided stocking allotments are not exceeded (as determined by WDFW, YN and CCT fishery managers, as applicable; Banks Lake may be utilized as a last resort if stocking allotments for area lakes have already been met and/or if access to appropriate locations is inhibited – i.e., snow, ice, washouts, etc.).

5. In the event a surplus is identified, WDFW and the appropriate Hatchery Committee(s) will be notified via email no later than two weeks prior to fish needing to be moved off station or to another program.

In addition, surplus fish, including broodstock, will be distributed at the earliest possible life-stage (e.g., prespawn adults, eyed-egg, fry) per WDFW policy. If excess WxW production from any of the conservation programs occurs, the priority will be to incorporate those progeny either into an available conservation program (if a shortfall exists) or into the closest safety net program (in this case it would be the Methow safety net [MSN]). Excess safety net fish from the MSN will then be managed in accordance with the guidelines above.

Wenatchee Summer Steelhead:

In the event excess HxH juveniles are produced resulting from higher than expected in-hatchery survival, fecundities, etc.), the parties agree that distribution of juveniles will follow the following priority matrix:

1. Used to support shortfalls in the Ringold SHD program provided fish health and/or marking requirements for the program can be met.

2. Out-planted to landlocked lakes within Chelan, Douglas, or Grant counties provided fish health requirements can be met or provided stocking allotments are not exceeded (as determined by WDFW, YN and CCT fishery managers, as applicable; Banks Lake may be utilized as a last resort if stocking allotments for area lakes have already been met and/or if access to appropriate locations is inhibited – i.e., snow, ice, washouts, etc.).

3. In the event a surplus is identified, WDFW and the appropriate Hatchery Committee(s) will be notified via email no later than two weeks prior to fish needing to be moved off station or to another program. This is to ensure adequate and appropriate logistics can be coordinated between affected parties.

In addition, surplus fish, including broodstock, will be distributed at the earliest possible life-stage (e.g., prespawn adults, eyed-egg, fry) per WDFW policy. If excess WxW production from the conservation program occurs, the priority will be to incorporate those progeny into the closest safety net program Excess safety net fish will then be managed in accordance with the guidelines above.

Surplus Upper Columbia Juvenile Spring Chinook Management

Methow Sub-basin

In the event excess juveniles are produced from Methow Sub-basin spring Chinook programs, the parties agree that distribution of juveniles will follow the following priority matrix:

1. Excess WxW progeny from the Methow conservation program(s) may be used to support shortfalls in the WNFH safety net program provided fish health and/or marking requirements for the program can be met.

2. Excess progeny from HO broodstock which *may* be collected to support the aggregate DPUD/GPUD/CPUD production obligation may be used to support any potential shortfall in the WNFH safety net program provided fish health and/or marking requirements for the program can be met.

3. In the event no other option exists within the Methow Sub-basin, excess hatchery progeny originating from the aggregate PUD production obligation, may be used to support the CCT 10(j) spring Chinook program in the Okanogan Sub-basin provided fish health and/or marking requirements can be met.

4. In the event no other option exists for excess hatchery progeny within the Methow Sub-basin, Banks Lake may be utilized as a last resort provided fish health requirements can be met.

5. In the event a surplus is identified, WDFW and the appropriate Hatchery Committee(s) will be notified via email no later than two weeks prior to fish needing to be moved off station or to another program. This is to ensure adequate and appropriate logistics can be coordinated between affected parties.

In addition, surplus fish, including broodstock, will be distributed at the earliest possible life-stage (e.g., prespawn adults, eyed-egg, fry) per WDFW policy.

Wenatchee Sub-basin

In the event excess juveniles are produced from Wenatchee Sub-basin spring Chinook programs (excluding Leavenworth), the parties agree that distribution of juveniles will follow the following priority matrix:

1. Excess progeny from the Chiwawa conservation program may be used to support shortfalls in the Nason conservation program provided fish health and/or marking requirements for the program can be met.

2. Excess progeny from the Nason conservation program may be used to support the Chiwawa conservation program provided they are progeny from females with assignment probabilities >95%. Additionally, it will require that fish health and/or marking requirements for the program can be met.

3. In the event excess NO production from the Nason program is not needed to or cannot support the Chiwawa (for reasons of fish health, marking, or ability to identify assignment probability), they will be incorporated into the Nason safety net program and prioritized over HxH progeny.

4. Excess progeny from the HO contingency broodstock collected for the Chiwawa program may be used to support any potential shortfall in the Nason safety net program provided fish health and/or marking requirements for the program can be met.

5. In the event no other option exists for excess hatchery progeny within the Wenatchee Sub-basin, Banks Lake may be utilized as a last resort provided fish health requirements can be met.

6. In the event a surplus is identified, WDFW and the appropriate Hatchery Committee(s) will be notified via email no later than two weeks prior to fish needing to be moved off station or to another program. This is to ensure adequate and appropriate logistics can be coordinated between affected parties.

In addition, surplus fish, including broodstock, will be distributed at the earliest possible life-stage (e.g., prespawn adults, eyed-egg, fry) per WDFW policy.

Appendix H

DRAFT

Alternative Plan for 2019 BY and beyond, for Methow Sub-basin Conservation Steelhead Programs

Introduction

The objective of this draft plan is to provide a thumbnail approach for mitigating genetic concerns specifically in the Twisp Conservation program, and describe our alternative for future implementation (2018 and beyond) for Methow Subbasin conservation steelhead programs (Twisp and Winthrop NFH). Direction herein is general with seasonal/run-specific technical details to be worked out annually between operators and formalized through broodstock collection protocols and steelhead-specific management plans. Our intent for this memo is to serve as a vehicle for the Hatchery Committee to approve this direction by vote. While this plan is being presented as a preferred course of action by the parties, approval (and further refinement of a long term plan) is contingent upon successful broodstock collection of the 2018 brood. No modifications to program size or release numbers are proposed – only modification of brood stocking methodology, rearing/release strategies and parentage.

Genetic analysis of returning adult steelhead at the Twisp River weir as part of the Relative Reproductive Success Study, indicated that relatedness among the returning hatchery origin adults was high (T. Seamons, WDFW Genetics Lab, pers. comm.). This is not surprising given the small program size (Table 1), and may result in a reduction in genetic diversity and N_e, consistent with effects described in Ryman and Laikre (1991), hereafter “Ryman-Laikre” or “RL” effects.

In response to concerns about minimizing the potential long term risks/effects associated with RL, the HCP-HC and co-managers are looking to adopt a strategy to address potential (or increased) RL effects in the Twisp population as well as having a more integrated approach to steelhead conservation programs in the Methow sub-basin. Mitigating actions were selected with goals to increase genetic diversity, reduce risk of inbreeding on the spawning grounds, and increase N_e. Actions includes release of age-2 (S2) WNFH conservation program juveniles into the Twisp River and compositing a portion of the Twisp and WNFH conservation program broodstock (while retaining a small Twisp WxW (S1) release. Specifically, returning spawners will originate from a greater number of less-related parents compared to the resulting return if these actions are not undertaken.

From the alternatives discussed by a small work group, a hybrid approach (hereafter referred to as alterative 3) between a couple alternatives was developed (and is preferred) that aims to retain Twisp genetics within the Twisp basin but includes incorporation of non-Twisp conservation program genetics.

Alternative 3 was developed based on the desire to protect any remaining or developing Twisp genetic stock structure while balancing and mitigating for genetic concerns by managing N_e and potential spawner relatedness concerns. The major point by which Alt. 3 differs from other alternatives discussed is that a small Twisp x Twisp broodstock would continue to be operated instead of full compositing. No overall changes to current production and release levels would occur. Approximately six Twisp x Twisp (NOR) crosses would produce approximately 24K smolts for release back to the Twisp River. Annual Twisp releases would also include a 24K co-release of S2 smolts from the WNFH conservation program, allowing for unrelated returning adults to provide an increased level of genetic diversity into the Twisp to combat low N_e and reduce risk of inbreeding. This strategy would also provide an evaluation opportunity where potential Twisp stock performance could be evaluated against WNFH conservation program smolts, providing management guidance for continued future direction.

Implementation details for Alternative 3 follow:

Broodstock Collection

- Combined broodstock collection (joint DPUD, WDFW, USFWS, and YN effort)
  - Collection occurs throughout the Methow River, including below-Twisp River angling, Twisp Weir, and WNFH/MFH hatchery infrastructure
  - Broodstock Targets
    - Approximately 6-8* pairs NORs collected at Twisp Weir (half of Twisp program)
    - Approximately 61-65* NOR pairs (WNFH program plus half of Twisp program) collected throughout the Methow River via angling
    - As a contingency for under-collection of broodstock sufficient to fulfil the two components of Twisp-release production, broodstock collection at Twisp Weir could be increased to the traditional collection target of 13 pairs, as needed.
    - *Flexibility required in targets for variation in escapement, fecundity, inclusion of hatchery-origin brood (as per BiOp), etc.
  - All broodstock transferred to WNFH for holding and spawning
    - DPUD may collect up to 37 pairs of conservation program returns (Ad+CWT and CWT-only) at Wells Dam and/or via angling consistent with conservation program efforts and direct-transfer to Wells Hatchery for use in safety-net program
  - Data management for broodstock collection and spawning at WNFH will be primary responsibility of USFWS MCFWCO (all data would be shared with WDFW and DPUD to allow completion of HCP-HC related reports):
    - All broodstock uniquely PIT-tagged upon capture/transfer for assignment on spawn days
    - PIT data tied to collection date/location, mark, DNA samples
    - USFWS will provide standardized effort collection information to all angling participants
  - Adult management will continue to be a large part of broodstock collection efforts
    - Guided by terms and conditions for minimum escapement, pNOB, and mitigation requirements in BiOp
    - Supported generally (i.e. without run-specific details) in annual broodstock collection protocols (e.g. Tonseth 2017)

- Supported specifically (i.e. includes run-specific details) by annual FMEP and targets/goals established by small Methow Steelhead Working Group

Spawning

- All conservation program spawning will occur at WNFH
  - Spawning will be 2x2 factorial crosses
  - Half of Twisp program will be Twisp weir collected NOR x Twisp weir collected NOR as feasible. Individuals PIT-tagged as juveniles in the Twisp will be treated the same.
  - WNFH program and remaining half of Twisp program will be Methow Subbasin NOR x NOR as feasible
  - All NOR females will be live-spawned & transferred to YN Kelt Program
  - USFWS MCFWCO will collect and provide all spawning biological and cross data to WDFW M&E staff.

Gamete Management & Smolt Release

- Maintain 48K total smolt release in Twisp River
  - 24K will be known-Twisp NOR x NOR spawned at WNFH but sent to Wells for S1 rearing
  - 24K will be representative cross-section of WNFH component, reared as S2 smolts at WNFH
  - All releases will be direct smolt plants at Buttermilk Bridge (RKm 21)
- Maintain 100K-200K total conservation program smolt release to Methow Sub-basin outside Twisp
  - 24K cross-section of WNFH population will be transferred to Wells Hatchery for S1 rearing for WNFH on-station or alternative release sites in Methow Subbasin.
  - 24K cross-section of WNFH population will be reared as S2 on-station as paired release for 24K S1 group (above) for potential alternative release strategies, as per above. Any alternative release strategies will guided by JFP and consider need for gradual implementation and patience in awaiting environmental response to management changes.
  - Remaining 52-152K of WNFH population will be reared as S2 smolts for on-station release.

[1]WNFH program subject to pNOB/production sliding scale in BiOp.
[2]Initially Methow R. at WNFH but may include alternative offsite release strategies subject to JFP and HCP- HC guidance and BiOp terms and conditions. Would be paired S1 and S2 release.
[3]Methow Safety-net program released in Methow River at Lower Burma Bridge.

Discussion

Alternative 3 was proposed by the working group as it appears to provide the best compromise while also including measures to address the Spatial Structure and Diversity VSPs, by attempting to maintain (or allow) development of local stock structure in the Twisp Watershed. In addition, Alternative 3 provides a higher probability of finding an effective conservation hatchery strategy for the Twisp River, and elsewhere in the Methow Subbasin because it uses three conservation hatchery strategies: 1) local WxW Twisp Program, 2) Methow Composite S1 program, and 3) Methow Composite S2 program.

Table 2. Illustration of out-year effects of 2017 actions and proposed Alternative 3 on Twisp River spawning ground age/program composition.

Spawn/ Escapement Yr.	Age/Program composition of spawners (HOR only) on spawning grounds - Twisp Watershed only

[2]No BY'17 Twisp Program was developed; brood were composited. This column displays return composition if status quo were to return in 2018.

Appendix I

2019 Brood Program Specific Rearing and Release Plans

Unless specifically detailed below, rearing and release protocols will follow the number, date, and location identified in Appendix B. In addition, all releases will prioritize nighttime or necessary, late afternoon release timing to reduce potential predation related impacts. Release timing will also take advantage of increasing flows and turbidity to further provide improved post release survival advantages.

Methow Summer Chinook (Carlton Acclimation Facility):

Rearing – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

Release - The summer Chinook salmon acclimated at the Carlton Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),
- all fish will be released when Columbia River and Methow River flows are predicted to be satisfactory,
- all fish will be released no later than May 7 regardless of flow conditions,
- attempt's will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in the Methow River are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Methow River flows are not satisfactory due to insufficient snow pack.

Nason Creek spring Chinook (Nason Acclimation Facility):

Rearing – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

Release - Spring Chinook salmon acclimated at the Nason Creek Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),
- all fish will be released when Columbia River and Nason Creek flows/conditions are predicted to be satisfactory,
- all fish will be released no later than May 7 regardless of flow conditions,
- attempts will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in Nason Creek are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Nason Creek flows are not satisfactory due to insufficient snow pack.

Wenatchee Summer Steelhead

Final Memorandum

Date: March 12, 2018

To: Rock Island and Rocky Reach HCP Hatchery Committees

From: Catherine Willard (CPUD), Scott Hopkins (CPUD), and Chris Moran (WDFW)

Re: Wenatchee Steelhead Release Plan (Brood Years 2017 to 2019)

<u>Background</u>

Chelan PUD is required to produce 247,300 steelhead smolts for release into the Wenatchee River Basin as part of the Rock Island and Rocky Reach HCP requirements. Through the end of January 2018, approximately 257,142 Wenatchee summer steelhead (128,585 HxH and 128,557 WxW) are on station at the Chiwawa Acclimation Facility (Chiwawa AF).

Beginning in winter 2011 the Chelan PUD Wenatchee River steelhead program was relocated to the Chiwawa AF following significant upgrades to accommodate tributary based overwinter acclimation for the Wenatchee steelhead program. Steelhead are transferred from Eastbank and Chelan Fish Hatcheries to the Chiwawa AF in November and released in April through May. Overwinter acclimation at the Chiwawa AF may have resulted in tradeoffs between program objectives associated with minimizing stray rates and those associated with maximizing survival. Overwinter acclimation at the Chiwawa AF has likely reduced stray rates. Based on PIT-tag analyses, on average for brood years 2011 and 2012 (overwinter acclimated at Chiwawa AF), about 4% of the hatchery steelhead returns were last detected in streams outside the Wenatchee River Basin. This is compared to an average stray rate of 25% for brood years 2005 to 2010 (not overwinter acclimated at Chiwawa AF). Mean juvenile survival from release to McNary Dam for brood years 2005 to 2010 (not overwinter acclimated at Chiwawa AF) was 54.3% compared to brood years 2011 to 2015 (overwinter acclimated at Chiwawa AF) of 30.1% (Figure 1).

The body size of smolts of steelhead originating from hatchery releases has long been believed to affect their post release survival and therefore the number of adult returns (Larson and Ward 1955; Wagner et al. 1963; Tipping 1997). Juveniles released at a larger size generally survive to maturity at a higher rate (Clarke et al. 2014). Size at release data from the Wenatchee steelhead program indicates that as fish size at release increases, juvenile survival to McNary also increases (Figure 2). The mean size at release for brood years 2005 to 2010 (not overwintered at Chiwawa AF) was 6 FPP compared to 10 FPP for brood years 2011 to 2016 (overwinter acclimated at Chiwawa AF).

Chelan PUD and WDFW (the Permit Holders) were issued Permit 18583 (Section 10) for operation, monitoring and evaluation of the Wenatchee River summer steelhead hatchery program in December of 2017. A special condition of this permit is to minimize residualism rates for hatchery releases and maximize the rate and probability of downstream migration. The presence of multiple confounding variables, including brood origin, smolt size, rearing vessel, water source, release date, release location, and release strategy has made it challenging to fully evaluate survival to McNary based on the size of release of the Wenatchee steelhead program.

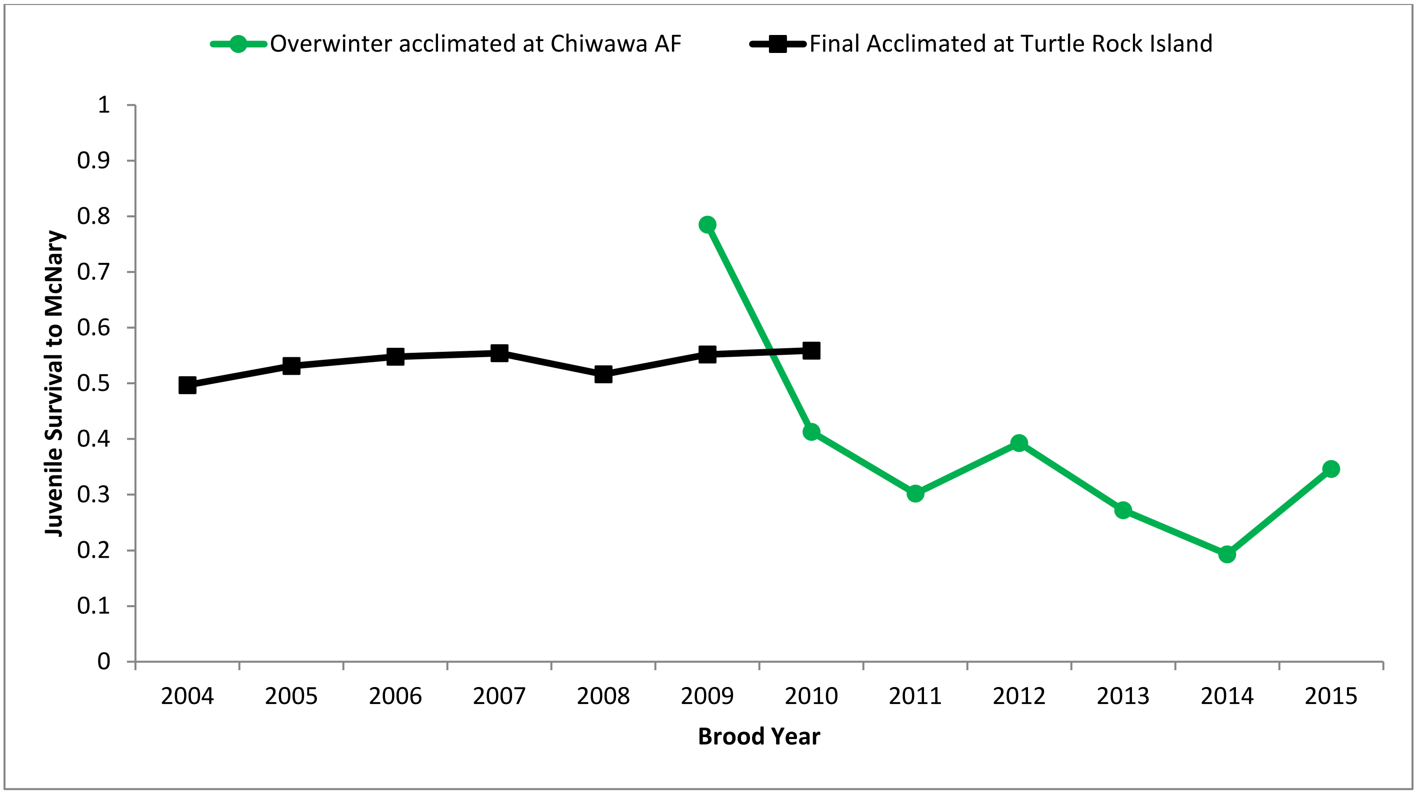

Figure 1. Juvenile outmigration survival to McNary for the Wenatchee summer steelhead program final acclimated at Turtle Rock Island and overwinter acclimated at Chiwawa Acclimation Facility.

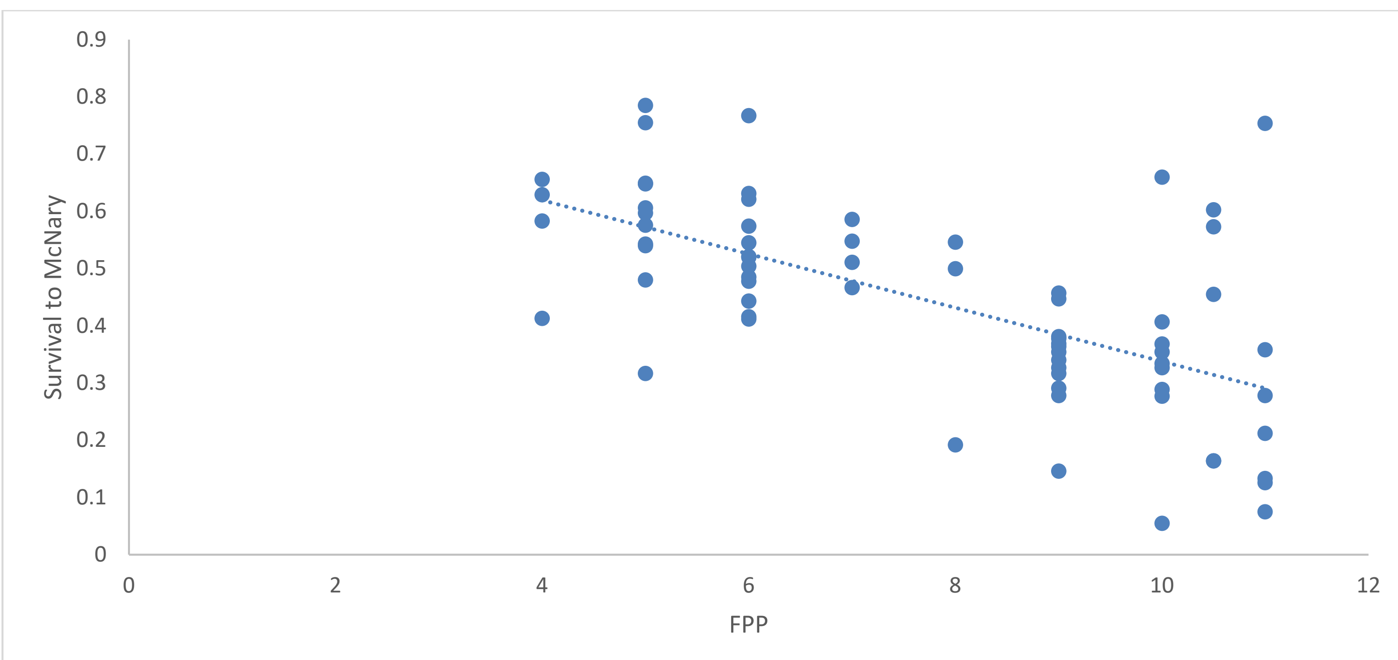

Figure 2. Juvenile outmigration survival to McNary and size of release data for the Wenatchee steelhead program, brood years 2005 to 2016.

Post-release performance of steelhead reared in the partial water reuse circular vessels (RAS) and traditional flow through raceways (RCY) have not consistently or thoroughly compared due to confounding variables present. RAS versus RCY comparisons may aid in future management decisions and improved performance of the Wenatchee steelhead program.

2018-2020 Release Strategy Objectives

- Evaluate survival based on size at release to McNary Dam to inform best hatchery management practices for hatchery releases that optimize homing fidelity, minimize residualism, maximize out-migration survival, and minimize negative ecological interactions (NMFS Wenatchee River Steelhead Section 10 Permit #18583).
- Evaluate rearing vessel Raceway 2 (RCY 2) (traditional flow through raceway) and partial water reuse circular vessel (RAS 1 and RAS 3).
- Minimize confounding variables (i.e. rearing vessel, release timing, flow conditions, release strategy, release location.) to evaluate size at release.
- Utilize data collected from the 2018-2020 Wenatchee River Steelhead release to assess applicable monitoring and evaluation objectives (i.e., Objectives 4 and 6) for the Wenatchee River summer steelhead hatchery program (Hillman et al. 2017).

Methods

Through January 2018, RCY 2 contain 232,388 steelhead (103,803 WxW and 128,585 HxH) and RAS 1 and 3 contain 24,754 WxW steelhead. PIT-tagged WxW and HxH steelhead located in RCY 2 will be evaluated based on size at release. PIT-tagged WxW steelhead located in RCY 2 and RAS 1/RAS 3 will be used to evaluate rearing vessel type. RAS 1/RAS 3 steelhead will be PIT tagged mid-February. RCY 2 fish will be PIT-tagged beginning the last week of February and two size classes will be targeted for PIT-tagging (small and medium). Each treatment group will contain approximately 11,000 PIT-tagged fish ((statistical power $1-\beta$ = 0.80; α = 0.10, two-tailed) (Skalski 2018)) (Table 1). To minimize confounding variables, all PIT-tagged fish will be directly released at one release location on the same day.

- Cormack-Jolly–Seber survival probabilities to MCN will be calculated for each release group using recaptures of PIT-tagged fish.
- The percentage of PIT-tagged fish detected in the Wenatchee sub-basin after July 1 of the year of release will be calculated to estimate potential residualism for each release group.

Table 1. Treatments for evaluation.

Vessel	Brood Origin	Treatment	Estimated # PIT-tagged	Treatment PIT release size
RCY2	HxH	Size	5,500 small	11,000 Small Mixed
RCY2	WxW	Size	5,500 small	
RCY2	HxH	Size	5,500 medium	11,000 Medium Mixed
RCY2	WxW	Size	5,500 medium	
RCY 2	WxW	Vessel Type	11,000	11,000 WxW RCY 2
RAS1/RAS 3	WxW	Vessel Type	11,000	11,000 RAS1/RAS 3

Release Timing

In an effort to more closely align hatchery steelhead releases with the peak outmigration period for wild steelhead and potentially increase juvenile outmigration survival, all fish located at the Chiwawa AF will be released by May 8th. In addition, every attempt will be made to release all of the program within the shortest feasible window possible, when optimal river conditions exist, and during the afternoon/early evening.

Release Location

Release locations in 2018 will be the same as the previous two years for non-PIT tagged fish. PIT-tagged fish will be released at one release location on the same day to the Chiwawa River (Table 2).

Pre-release Monitoring and Evaluation

Throughout acclimation and release, established sampling, transfer and release protocols will be followed (Hillman et al. 2017). Additionally, an extensive pre-release sample of 10% of the PIT-tagged fish will occur within one week prior to release. In addition to measuring fork length, an assessment of smolt index and precocial maturation will be conducted via non-lethal sampling. The pre-release fork length data will be used to create a linear regression equation to predict fork length at release of fish not measured during the pre-release sample.

Table 2. Steelhead release numbers and locations, 2018.

Vessel	Origin[1]	Estimated Number Released[2]	Estimated # PIT-tagged	Destination	rkm
RCY2	Mixed	58,067	TBD	Nason	7
		58,067		**Total**	
RCY2	Mixed	97,749	TBD	U. Wenatchee	79.2
		97,749		**Total**	
RAS 1+3	WxW	24,754	11,000	Chiwawa	11.4
RCY2	Mixed	41,572	22,000	Chiwawa	11.4
		66,326		**Total**	
RCY2	Mixed	35,000	TBD	L. Wenatchee	40.2
		35,000			

[1]Mixed = HxH and WxW.
[2]Releases will occur between April 20 - May 8.

Additional Considerations

- To eliminate release location as a potential confounding variable, releasing all of the PIT-tagged fish into one release location is recommended.
  Which release location should be utilized? All PIT-tags released in Chiwawa River well upstream from the detection array (RK 11.4).
- A special condition of the permit is to minimize residualism rates for hatchery releases and maximize the rate and probability of downstream migration. To ensure the program works towards minimizing potential long term effects of residuals, the Permit Holders, through the HC process, will develop a plan that limits the number of residuals produced and attempts to identify an acceptable rate of residualism in the Wenatchee steelhead program by brood year 2018. This plan may include the following elements:
  - Methodology for establishing baseline conditions; concurrence of a performance standard threshold; criteria for determining exceedance/compliance with the performance standard.

Input on post-release sampling to conduct GSI sampling and assessment of smolt index? See "Methodology for Establishing Residualism Baseline Conditions of the Wenatchee River Summer Steelhead Hatchery Program" March 12, 2018, Rock Island and Rocky Reach HCPs HCs notes.

Appendix J

2018-2020 Brood year Adult Prophylactic Disease Management Plan for Eastbank Fish Hatchery Complex Spring and Summer Chinook Hatchery Programs.

Background: Hatchery broodstock disease profiles observed in some programs operating out of the Eastbank FH complex in 2017 (as well as other hatchery programs throughout the Columbia River Basin) resulted in higher than expected prespawn mortality and/or BKD ELISA results which required (under the terms and conditions of the Section 10 permits) culling eggs/fish at a higher rate than anticipated which put several programs considerably below the respective production targets. The inability to determine whether the deviation in performance in 2017 was the result of eliminating prophylactic antibiotic injection practices, as was historically conducted, or was related to environmental conditions (or a combination of both) has prompted WDFW to develop and implement a fish health treatment plan (adult broodstock only) beginning with the 2018 brood and running for at least three (3) consecutive brood years.

The overall goals are to primarily ensure integrated and/or recovery programs make the most efficient use of natural origin broodstock to avoid mining as well as maximize natural origin spawners while minimizing handling/unnecessary activities on broodstock. In addition where practical, we (WDFW) would like to see the use of antibiotics and other therapeutics reduced or eliminated over time. Having a controlled approach to evaluating the use of prophylactic treatments in these programs will allow the operators/managers to determine which programs may benefit from prophylactic treatments and which programs may be able to shift away from this practice, all of which is designed to reduce overall handling and associated effects as much as possible.

Methods: To minimize handling events, injections will be scheduled to occur either at collection or during sorting (such as during genetic sorting that occurs for the Nason spring Chinook program). Only females will be injected, in the intraperitoneal cavity (IP) with Draxin for BKD and if necessary, long acting Oxytetracycline for gram negative bacteria (i.e., *Columnaris*). Generally, injections will be prioritized for natural origin females as the control and hatchery origin females as the treatment for the spring Chinook programs. A slightly different approach will be used for each of the summer Chinook programs. All females receiving the injections will be considered the control given that this was the standard hatchery practice by which current disease result data sets and decisions are built on. All females will be PIT tagged at time of collection or injection to facilitate tracking of individual females (and possibly their progeny).

The results will be evaluated annually to determine if modifications to the current plan are necessary.

Program Specific Plans For 2019 Brood year:

Methow (Carlton/MEOK) Summer Chinook:

1) Collected at Wells Dam
2) 62 NO females are targeted for collection in 2019 with every other female will be injected at collection.
    a. Since the Twisp M&E staff are conducting run comp and broodstock collection activities at the Wells Dam East/West ladders, it makes sense for them to inject while the fish are sedated.

Chelan Falls Summer Chinook:

1) Collected at Well Hatchery Volunteer Trap
2) If injections cannot be accommodated at time of collection at Well Hatchery, adults collected over the course of a week will be placed at the head of the adult pond. At the end of the week, females will be PIT tagged and every other female will be injected then placed over the net and not handled again until spawning.
3) 195 HO females are targeted for collection and up to 97 will be injected.
4) Disease management may vary somewhat depending upon the determination of the pathogen in play (i.e., *Columnaris* may play a larger role than BKD which require different approaches).

Wenatchee Summer Chinook:

1) Collected at Dryden dams or Tumwater Dam.
2) No injections planned at this time. The Wenatchee summer Chinook program was the only EB program in 2017 which did not see a negative deviation in disease/prespawn mortality outcomes from the predicted so the 2019 plan is to stay consistent with the 2018 approach of no injections. If during the three year period, it appears the Wenatchee summer Chinook may benefit by evaluation of injection versus non-injection then we will make plans to accommodate that evaluation.
3) 137 NO females are targeted for collection and will not be injected.

Chiwawa Spring Chinook:

1) Collected at Tumwater Dam
    a. All previously PIT tagged Chiwawa NOR's collected will be combined with Nason Spring Chinook weekly collections at Eastbank.
    b. All Chiwawa NO females collected at Tumwater Dam will be injected during genetic sorting of the Nason Fish.
    c. HO females collected at Tumwater will not be injected.
2) Collected at Chiwawa Weir

   a. All female NO females collected at the weir will be injected at the time of collection.

3) 32 NO females are targeted for collection between the two locations and will be injected.
4) 4 HO females targeted for retention as part of the production shortfall backup, collected at Tumwater Dam will not be injected.

Nason Spring Chinook:

1) Collected at Tumwater Dam.
2) 26 NO females are targeted for retention and will be injected during genetic sorting.

37 HO females are targeted for retention. HO females will not be injected.

Appendix K

MID-COLUMBIA COHO BROODSTOCK

COLLECTION PROTOCOLS 2019

Yakama Nation

Fisheries Resource Management

Mid-Columbia Field Office

7051 Hwy. 97

Peshastin, Washington 98847

The Yakama Nation Fisheries Resource Management's (YN FRM) 2019 broodstock collection protocols for coho (*Oncorhynchus kisutch*) were developed to meet upper Columbia (Methow and Wenatchee basins) annual smolt release goals for 2021, as per the Mid-Columbia Coho Reintroduction Program's (MCCRP) Master Plan (YN 2017). Additionally, this document identifies the applicable operational planning to achieve adult collection goals and associated broodstock spawning conventions herein.

BROODSTOCK COLLECTION GOALS

Brood Year (BY) 2019 coho smolt production goals are 1,000,000 fish for release in the Wenatchee River basin and 1,000,000 fish for the Methow River basin.

Adult coho returning to the Wenatchee River basin will be collected at Tumwater Dam, Dryden Dam, Leavenworth National Fish Hatchery (LNFH), and/or Priest Rapids Dam (PRD); in order of collection priority. The program strives to achieve at least 50% of adult collections from Tumwater Dam with the remainder coming from Dryden Dam, LNFH and/or PRD. Coho collections from Tumwater Dam are important to encourage stock adaptation so that returning adults can reach key, upstream habitats within the upper basin. Based upon a phased approach, the Wenatchee program currently in Broodstock Development Phase II (BDPII; YN 2017). However, collecting sufficient female broodstock from Tumwater Dam has presented a challenge and identified the need for a contingency plan. The ratio of female to male coho navigating Tumwater Canyon to Tumwater Dam has been tilted heavily toward males. Due to this occurrence, the BDPII completion goal for the Wenatchee Basin has transitioned to collecting 50% of our female broodstock from Tumwater Dam for a three year period

In the Methow River basin, returning adults will be collected from Douglas County Public Utility District's (DCPUD) Wells Dam facilities (i.e., east and west ladders and Wells Fish Hatchery (FH) volitional channel), Winthrop National Fish Hatchery (Winthrop NFH), and Methow Fish Hatchery (Methow FH); in order of priority. Although project releases from Wells FH were concluded in 2013, some returning adults may be collected as volitional swim-ins to the facility's holding pond concurrent with summer Chinook and steelhead trapping efforts. The program will rely on Wells Dam facilities as primary collection locations to ensure a representative sample of returning adults from all in-basin release locations, as well as provide sufficient numbers of broodstock required for continued development of the Natural Production Implementation Phase (NPIP; YN, 2017) in 2021. In-basin collections will continue to include Winthrop NFH and Methow FH adult weir on a supplementary basis, as swim-ins to these facilities remain a key component in broodstock development. While coho have not been released from Methow FH, an adult weir will be used to collect returning adults since both hatcheries' surface water withdrawals come from a common, upstream diversion on the mainstem Methow River (Foghorn Irrigation Diversion). Broodstock collection goals for both Wenatchee and Methow programs are calculated from measured, mean survival rates that include pre-spawn adult mortality, average female fecundity, green egg survival, and hatch rates observed during past brood years.

In the Wenatchee River basin, collection of up to 1,264 adult coho will be necessary to release 1,000,000 smolts. **Table 1** illustrates the program's anticipated release, survival, and collection goals for brood year 2019**.** Throughout the program's history, adult coho sex ratios collected at Tumwater Dam have been tilted heavily towards males. If necessary, the likely disproportionate number of adult males may be reconciled by collecting additional adult females at alternative in-basin collection sites (i.e. - Dryden Dam or LNFH ladder).

Table 1. 2019 YN Wenatchee River Basin Program Release Target, Mean Survival, and Broodstock Collection Goal

Program target smolts released	Survival green egg to eyed [1]	Survival eyed egg to release[2]	Green eggs required	Average eggs per female[3]	Adult pre-spawn mortality[4]	Viable females required	Total female collection goal	Total adult collection goal [5]
1,000,000	87.4%	83.5%	1,370,258	2,778	6.5%	494	527	1,264

1. Due to unusual elevated mortality observed at the eyed egg stage in BY2014 & 2015, survival is based on an 9 yr. mean eyed egg rate for 2007- 2018 brood years, excluding 2014 & 2015.

2. Observed 7 yr. mean eyed to release survival rate includes 2008 to 2012 brood years, 2014 & 2015. 2013 was excluded as a large number of eggs were transferred to the Methow Basin. 2016 was excluded due to significant overwinter rearing predation at Leavenworth NFH. 2017 & 2018 percentages are yet to be determined.

3. Observed 12 yr. mean fecundity for 2007-2018 brood years.

4. Observed 12 yr. mean pre-spawn mortality observed in 2007-2018 adult brood years.

5. Based on observed, mean male-to-female ratio (57.3%M: 41.7%F) for 2008-2018 brood years.

In the Methow River basin, a maximum of 1,054 adult coho will be necessary to release 1,000,000 smolts. Anticipated release, survival, and collection goals for brood year 2019 are presented in **Table 2**. Throughout Broodstock Development Phase II (BDP II; YN 2017), Methow River basin collection goals were calculated as number of adult coho needed if broodstock were collected from Wells Dam and as swim-ins to Winthrop NFH and Methow FH to accomplish broodstock development goals as outlined in the Mid-Columbia Coho Master Plan (YN, 2017). After completion of BDP II in 2013, a programmatic transition was made to prioritize Wells Dam facilities to ensure collected adults were representative of all in-basin release locations. Since Wells Dam facilities will provide the primary brood source throughout the NPIP phases of the program, collection goals for 2019 are based on data collected at these facilities.

Table 2. 2019 YN Methow River Basin Program Release Target, Mean Survival, and Broodstock Collection Goal

Program target smolts released	Survival green egg to eyed [1]	Survival eyed egg to release[2]	Green eggs required	Average eggs per female [3]	Adult pre-spawn mortality[4]	Viable females required	Total female collection goal	Total adult collection goal [5]
1,000,000	84.6%	85.9%	1,376,057	2,728	4.4%	504	527	1,054

1. Observed 12 yr. mean eyed-egg rate for 2007- 2018 brood years.

2. Observed 10 yr. mean eyed to release survival rate for 2007-2016 brood years.

3. Observed 12 yr. mean fecundity for 2007-2018 brood years.

4. Observed 12 yr. mean pre-spawn mortality observed in BY 2007-2018 adults.

5. Observed 12 yr. mean male-to-female ratio for Wells Dam facilities (46.5%M: 53.5%F) for 2007-2018 broods. Total collection goal is based on a 1 M: 1 F ratio.

BROODSTOCK COLLECTION PROTOCOLS

Wenatchee River Basin

Past protocols focused on broodstock development in the sense of maximizing genetic diversity; attempting to collect a representative sample of returning adult coho from throughout the run. Based on information collected from 2000 to 2018, the first returning adult coho traditionally arrive at Dryden Dam during the second week of September. The run typically continues through the last week of November, with peak migration ordinarily occurring mid to late October. Migration timing over Tumwater Dam is characteristically one week later than observed at Dryden Dam. Beginning with brood year 2017, an effort to retain and distinctly floy tag first arriving fish at Dryden Dam has been instituted. Based on the strengthened ability of female coho to reach the Tumwater Dam in September versus October, a shift in prioritizing adults appearing early in the run has been set in place. Attaching the capture date specific tags allows a focus on mating as many early arriving pairs as possible at spawning. The long term result is anticipated to expand the annual number of adult coho arriving early in the run, thus increasing the number of adult female coho capable of ascending Tumwater Dam during optimal flow conditions.

Bi-weekly broodstock collection goals have been established for both Tumwater and Dryden dams and are illustrated in **Table 3.** Collection goals target a minimum of 50% of the broodstock from Tumwater Dam (YN 2017). Bi-weekly goals are intended to serve as a guide for collection from throughout the run but may be adjusted to ensure the newly implemented broodstock arrival time prioritization needs and adult accessibility are optimized. If during any week the broodstock collection goals are not met, the deficit will be carried over to the following week until the collection total is reconciled. Adults collected from PRD or LNFH will be assimilated into the combined weekly goal. A minimum of one male will be collected for each female to adhere to spawning protocols.

Table 3. 2019 Wenatchee River Basin Coho Broodstock Collection Goals

Calendar Week	9/1	9/8	9/15	9/22	9/29	10/6	10/13	10/20	10/27	11/3	11/10	11/17	TOTAL
Dryden Dam	1	5	14	47	52	90	131	124	107	39	18	4	632
Tumwater Dam	0	1	10	38	67	100	165	125	90	29	6	1	632
TOTALS	1	6	24	85	119	190	296	249	197	68	24	5	1,264

Between September 1 and November 2 of this year, broodstock collection at Dryden Dam will occur daily and in coordination with Washington Department of Fish and Wildlife's (WDFW) evaluation and monitoring staff and Eastbank Fish Hatchery (Eastbank FH) hatchery personnel, as it characteristically occurs concurrently with steelhead broodstock collection. YN will provide a minimum of two people each day to assist in operations and collection at Dryden Dam adult fish trapping facilities. Between November 3 and November 16, YN personnel ordinarily operate the trapping facility independently but will communicate with Eastbank FH, WDFW, and Chelan County Public Utility District (CCPUD) personnel regarding collections, trap maintenance, and operations. If YN staff foresees broodstock collection goals (through trapping efforts at Tumwater and Dryden dams) will not be met, adult coho may be collected at the LNFH adult ladder to prevent a deficit. Tumwater Dam operations will be coordinated with Eastbank FH personnel and/or WDFW evaluation crews and occur concurrently with WDFW steelhead brood collections.

Methow River Basin

Prior to 2005, coho broodstock collections for the Methow River program were solely conducted at Winthrop NFH; however, few coho completed this long migration and successful returnees were typically males. In 2005, the primary collection site shifted towards Wells Dam in an effort to intercept more returning Methow Basin coho and increase female collections in the process. Broodstock Development Phase I (BDP I) was initiated in 2006 and focused on eliminating the reliance on lower Columbia stocks and transitioning to a local broodstock. During BDP I, program adults began to demonstrate the ability to return in sufficient numbers to meet collection goals from both in-basin release locations (i.e., Winthrop NFH on-station raceways and back-channel pond) and Wells FH. By 2009, average contribution of swim-ins (Winthrop NFH and Methow FH combined) into the Methow broodstock had exceeded 50% (*avg.* = 52.7%) and were a predominant portion of the program. In 2010, the program transitioned to BDP II and swim-ins to these facilities were prioritized as the primary brood source, with collections at Wells Dam facilities providing supplementary adults. Broodstock Development Phase II was accomplished in 2013 for the Methow Program and a shift back to prioritizing collections at Wells Dam facilities was made in 2014. Collections in 2019 are intended to provide sufficient broodstock required for the continued development of NPIP in 2021, and will require incorporation of adults from all established, in-basin release locations. Since no in-basin collection locations currently exist (i.e., tributary collection weirs) that would provide for a representative sample of returning adults in-basin, Wells Dam facilities would provide those means. Adult collections will continue to occur at Winthrop NFH and Methow FH collection weir on an auxiliary basis, as swim-ins to these facilities will continue to be a key element to broodstock development.

At Wells Dam, proposed trapping operations would occur on the east and west ladders according to the following schedule (National Marine Fisheries Service (NMFS), 2017; Consultation Number WCR-2015-3778):

1) Sept 1- Sept 26: 3 days/week and 16 hrs/day
2) Sept 27-Oct 9: 5 days/week and 9 hrs/day
3) Oct 10- Dec 7: 7days/week and16 hrs/day

Trapping operations will be coordinated with WDFW and DCPUD and to maximize coinciding operations with WDFW evaluations and Wells FH summer steelhead and summer Chinook collections. If during this timeframe, WDFW/Wells FH is not operating one or both of the traps, YN personnel would assume full operations of both facilities and actively operate traps with all non-target fish being documented and passed upstream while minimizing handling. When operating the west ladder trap, coho salmon will be diverted directly from the ladder into the holding facility at Wells FH. Removal of coho from the temporary holding area, to include volitional swim-ins, will be coordinated with DCPUD/Wells FH personnel. YN staff will continue to transport collected adults at a minimum of three times per week with holding criteria to not exceed 150 coho at one time. During east ladder operations, trapped coho would be placed directly into a transport tank. All coho transported from Wells Dam facilities will have a unique mark to differentiate them at spawning from volunteer swim-ins at Winthrop NFH and Methow FH adult weir.

Supplemental collections at Winthrop NFH and Methow FH could, if required, occur up to seven days per week (24 hours/day) between September 1 and December 7 at both facilities (NMFS, 2017). Adults collected from Methow FH collection weir would be transported to Winthrop NFH for holding and spawning. All trapping operations at Methow FH will be coordinated with DCPUD.

Methow River basin weekly broodstock collection goals for 2019 are illustrated in **Table 4**. If during any week broodstock collection goals are not met, the deficit will carry over to subsequent weeks until collection totals are reconciled. Weekly trapping goals are intended to serve as a guide to ensure collection from throughout the run but may be adjusted mid-season to ensure that the total collection goal is met. Collection goals are expressed in numbers of adult coho needed if broodstock are solely collected from Wells Dam facilities. A minimum of one male will be collected for each female to adhere to spawning protocols.

Table 4. 2019 Methow River Basin Coho Collection Goals

Calendar Week	9/1	9/8	9/15	9/22	9/29	10/6	10/13	10/20	10/27	11/3	11/10	11/17	TOTAL

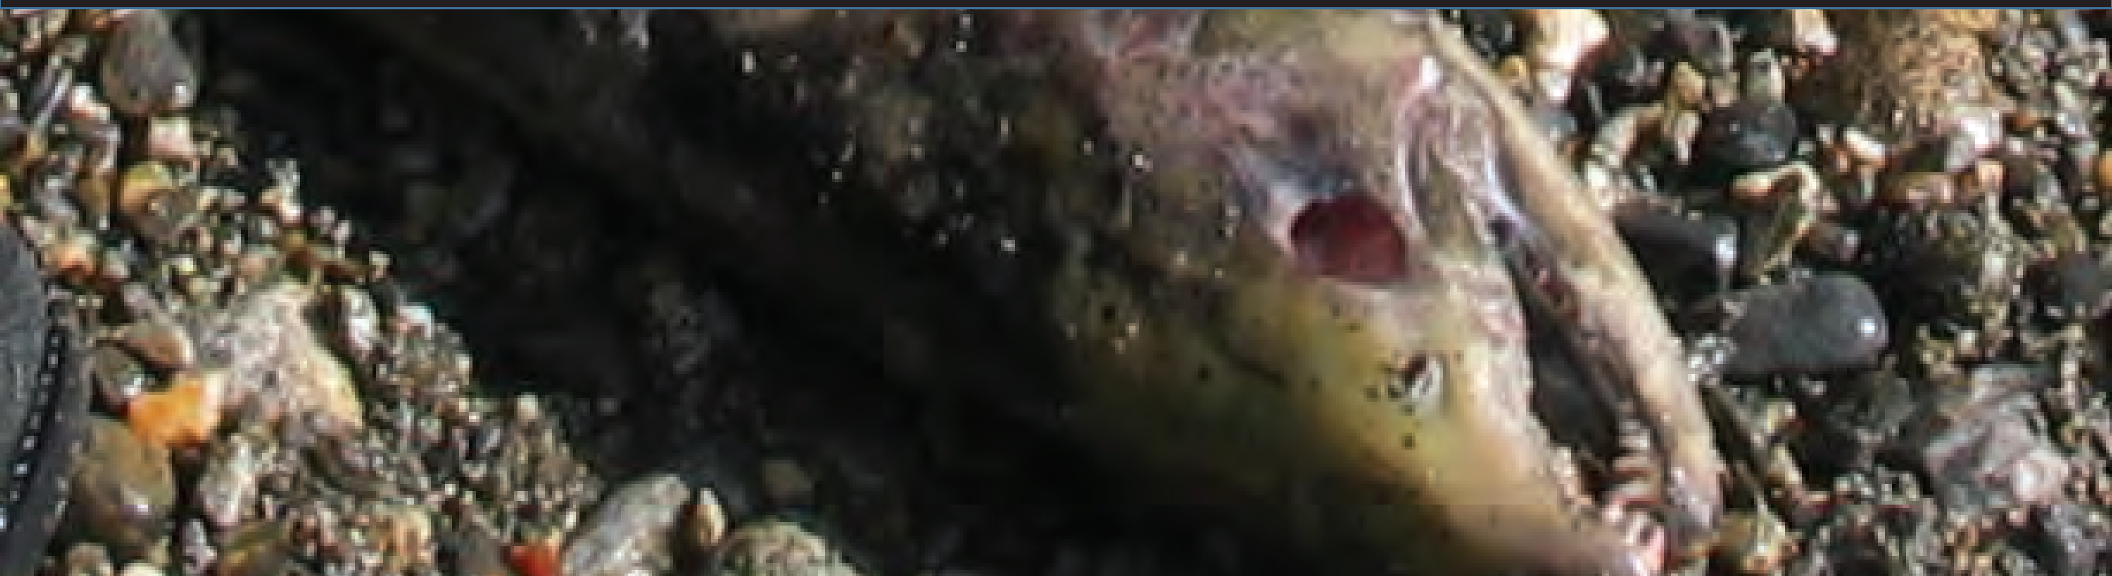
Attachment C

Spring Chinook Carcass Recovery Bias in the Upper Wenatchee Basin



Mike Hughes, Andrew Murdoch (WDFW)
Kevin See (Biomark)

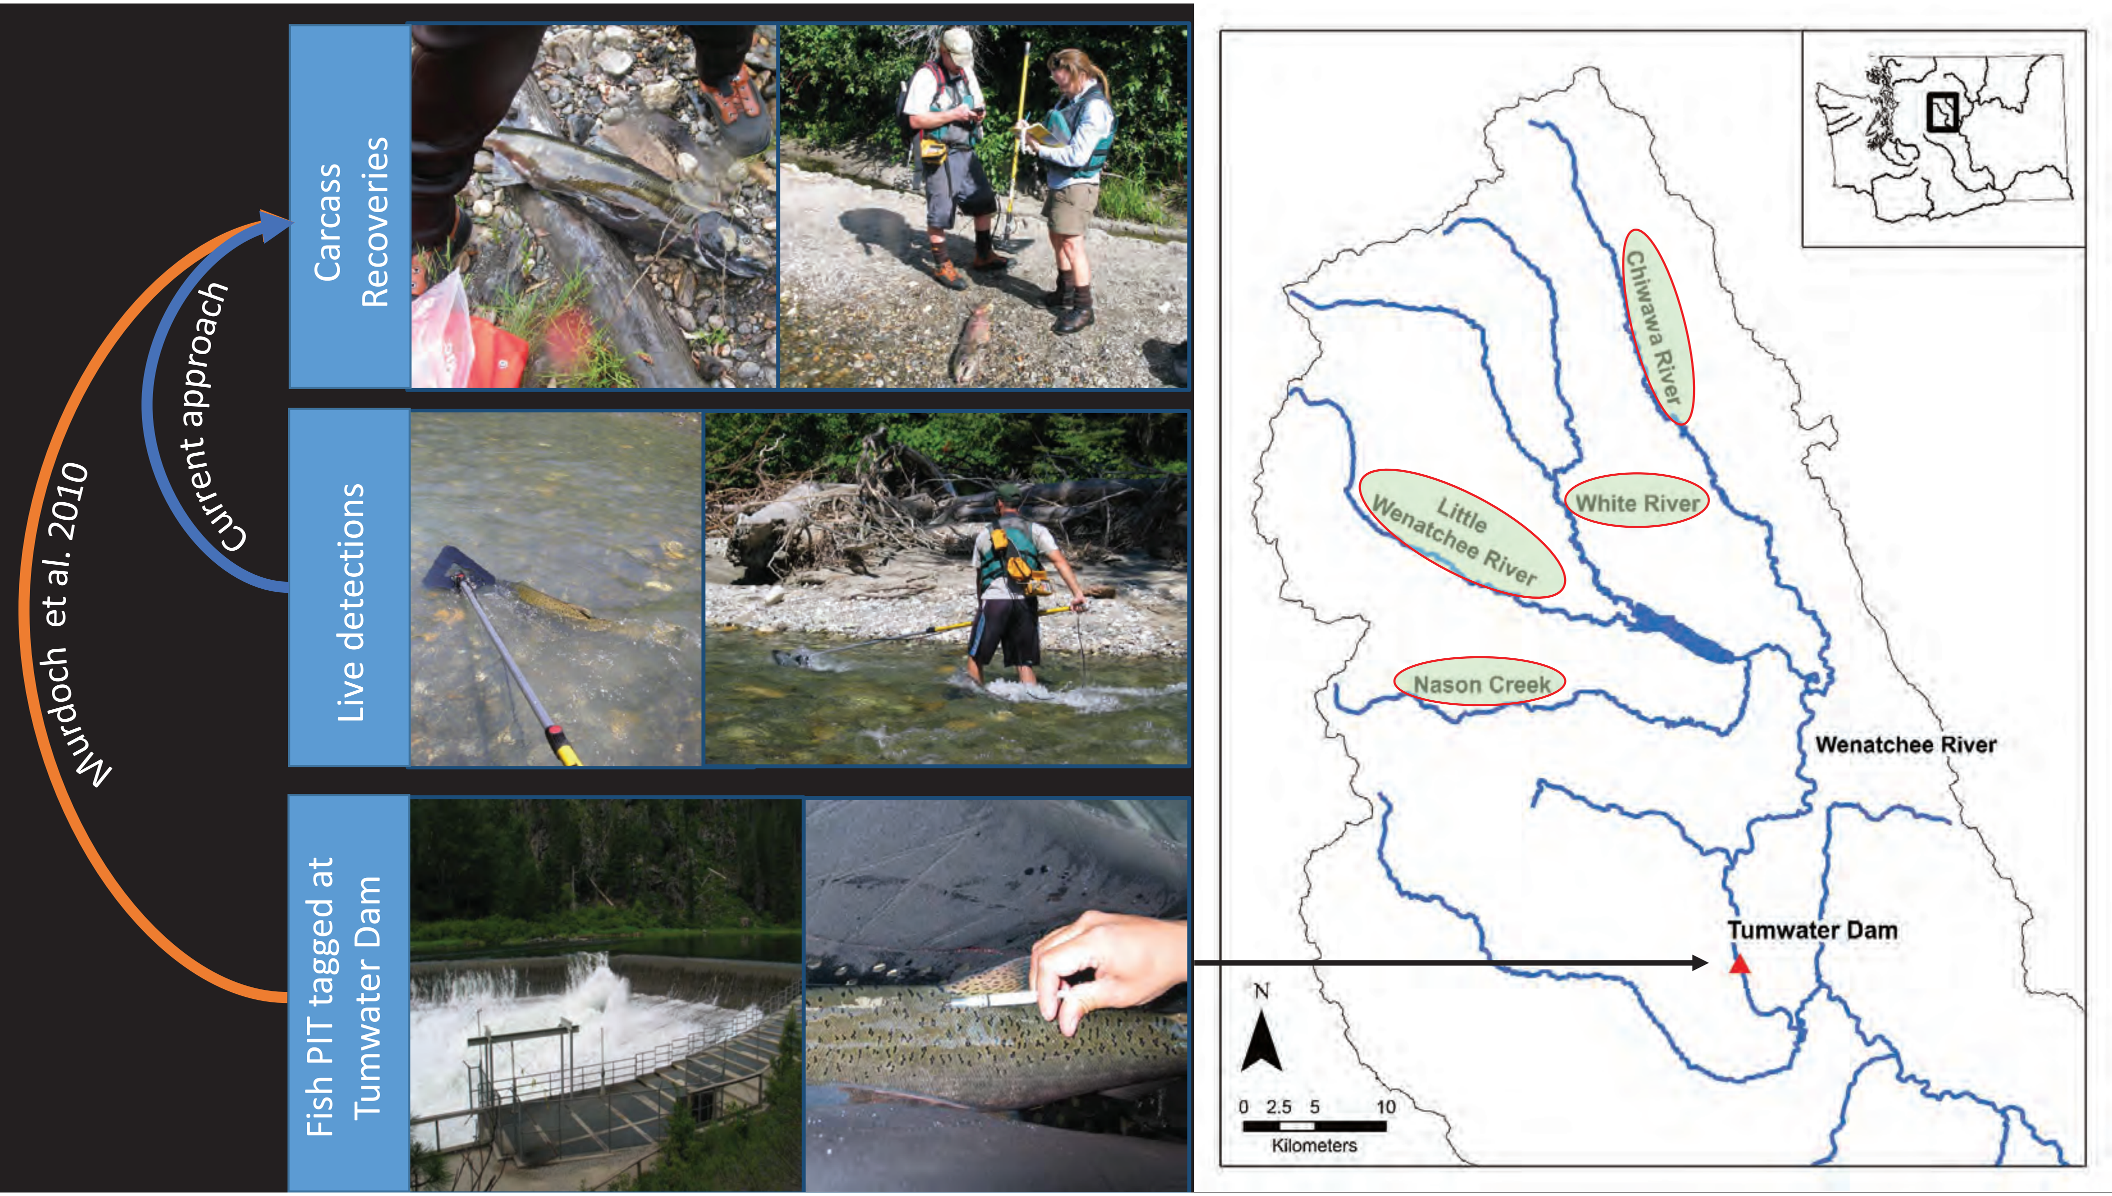
Utilization of Carcass Data

- Carcasses recovered on the spawning grounds are often used to reconstruct the demographics of a spawning population
- Assumes that these collections are truly a random sample of carcasses
- Carcass recovery probabilities have been shown to differ;
    - Sexes
    - Fish Size
- Resulting in a biased spawning population estimates

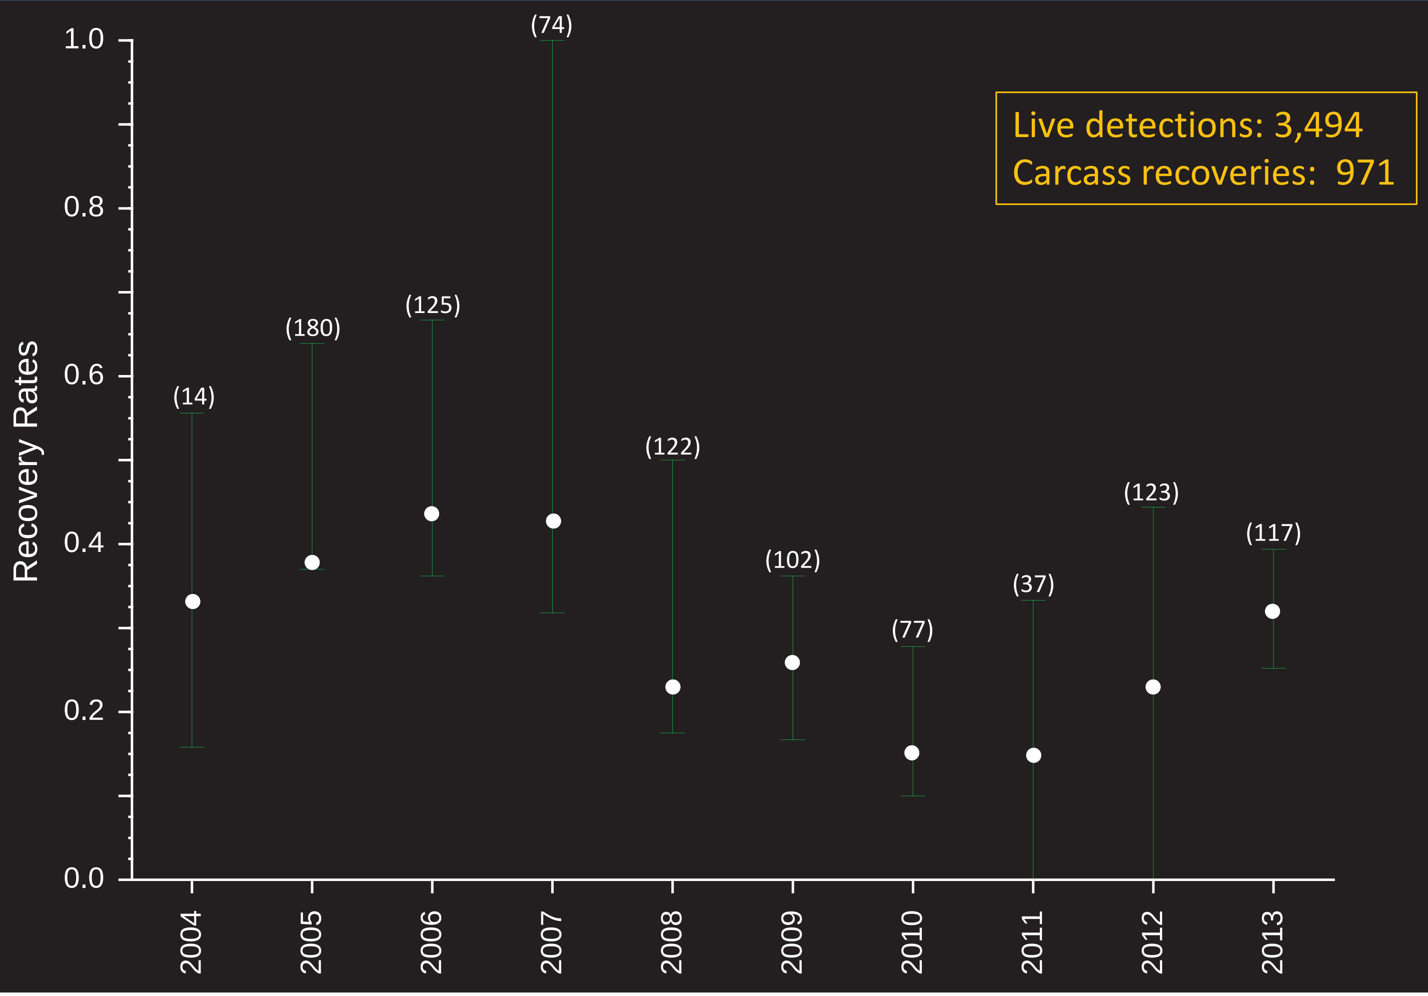
Study Objectives

- Evaluate carcass recovery rates and the factors that influence them
- Develop a model that predicts carcass recovery probabilities for spring Chinook Salmon in the upper Wenatchee Basin
- Recalculate the demographics of the spawning populations using corrected carcass recovery data
  - Preliminary results for Chiwawa River in 2011 and 2013

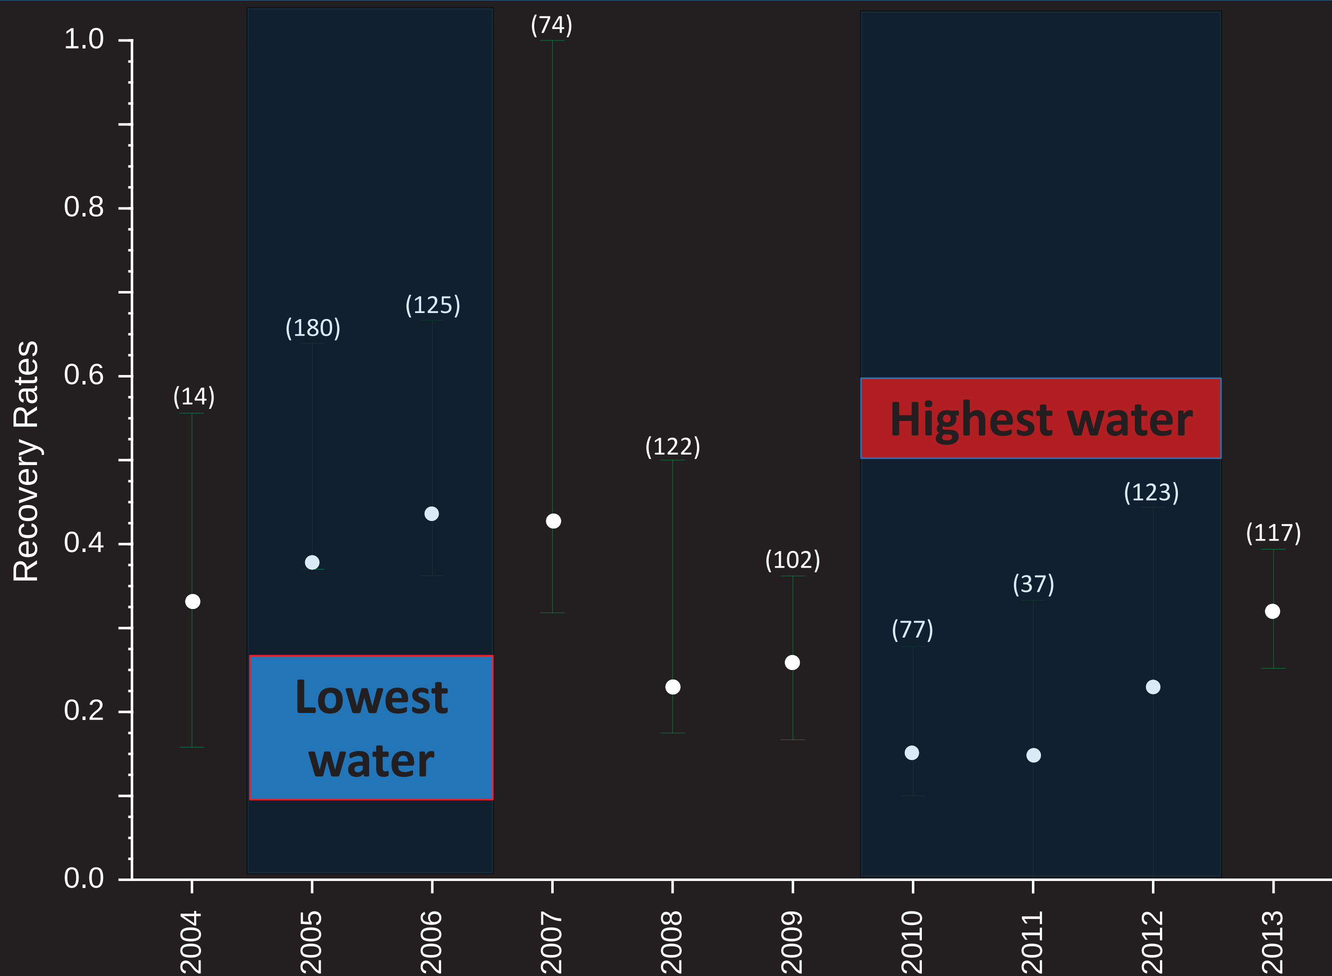
Attachment C



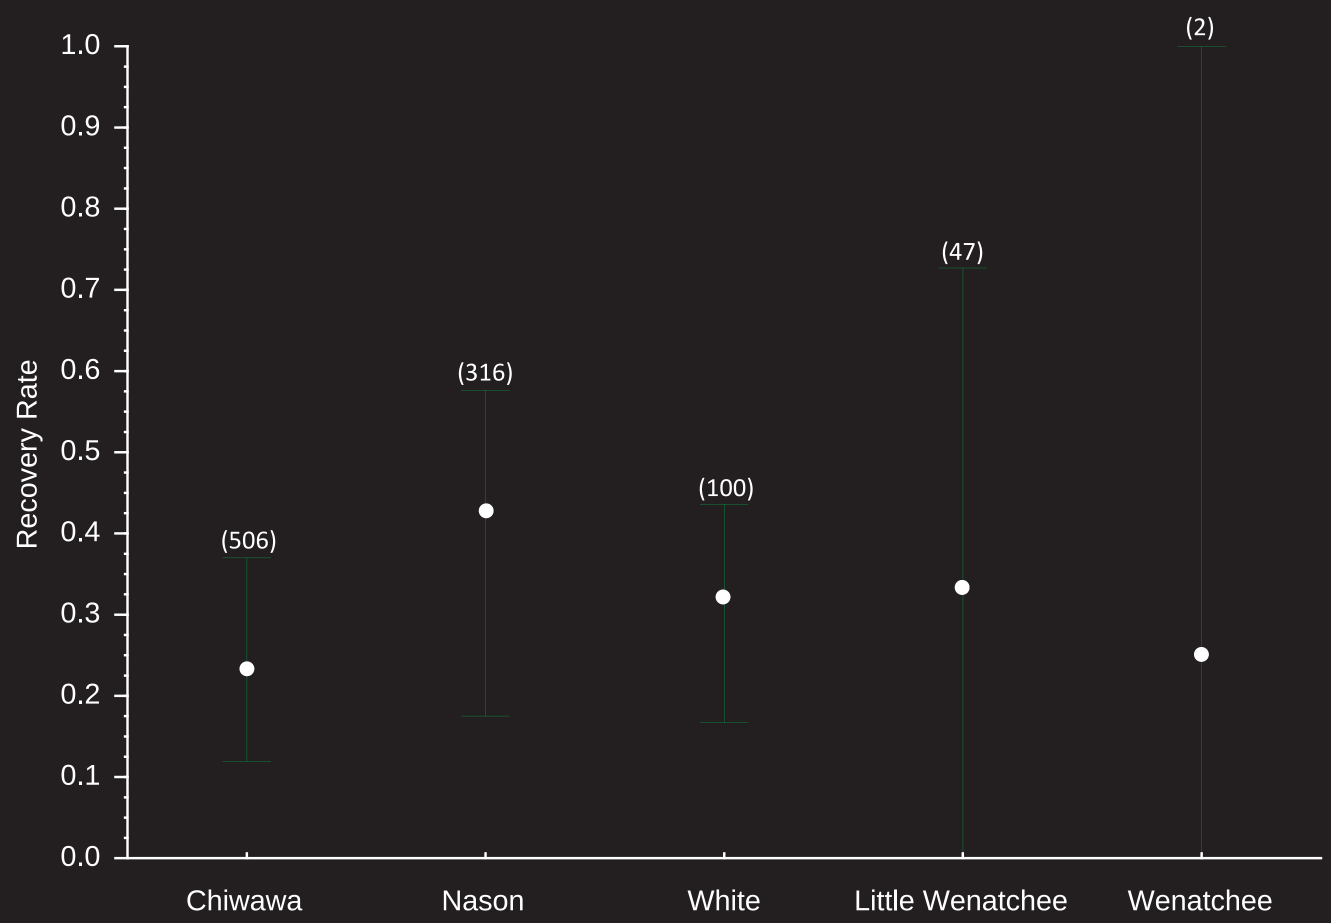
Recovery rates across all tributaries by year



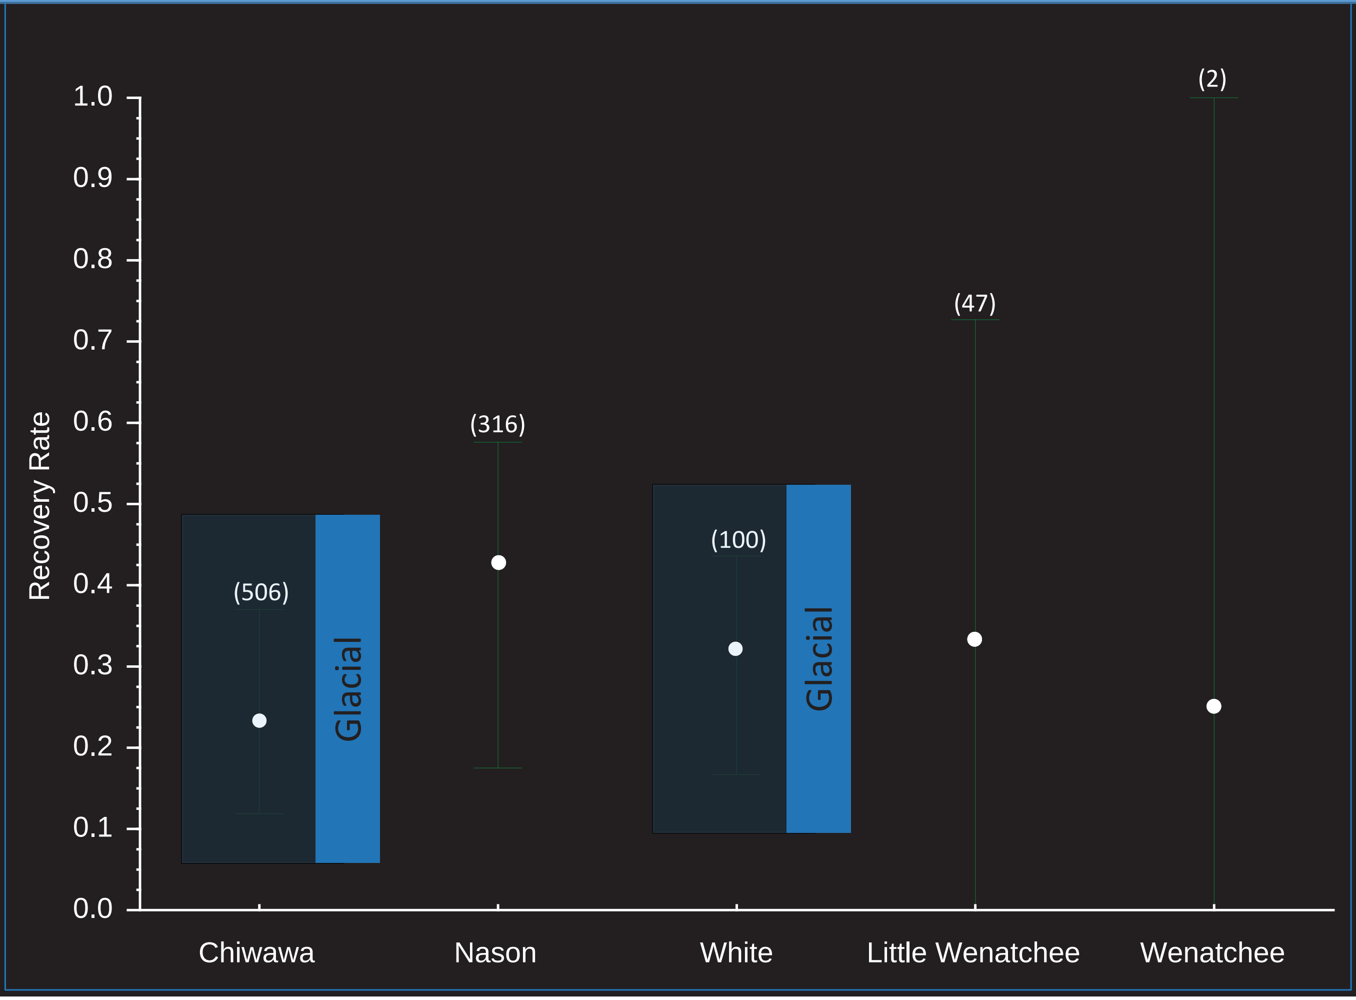
Recovery rates across all tributaries by year



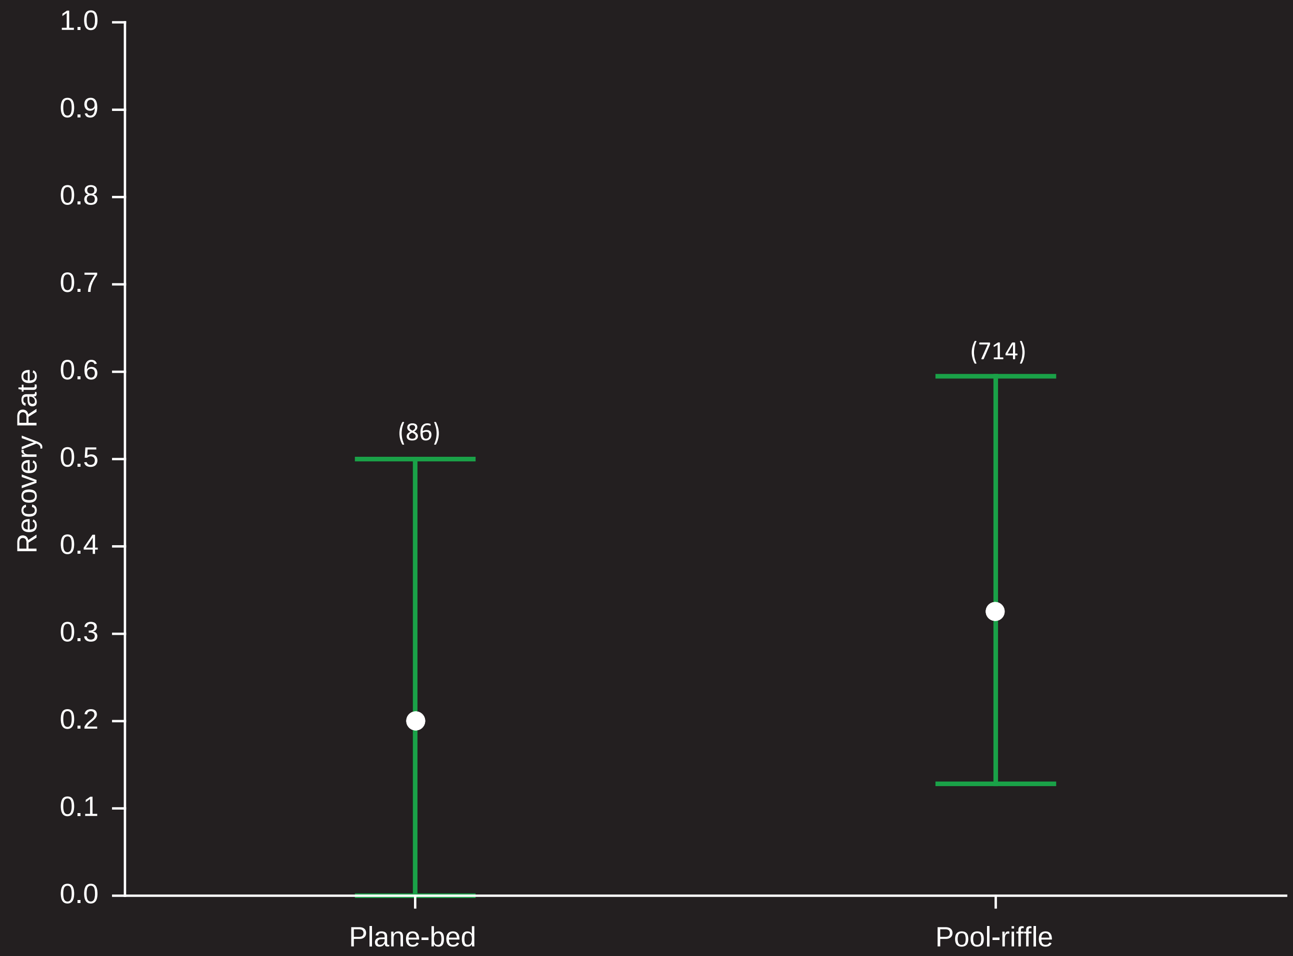
Median recovery rates by tributary



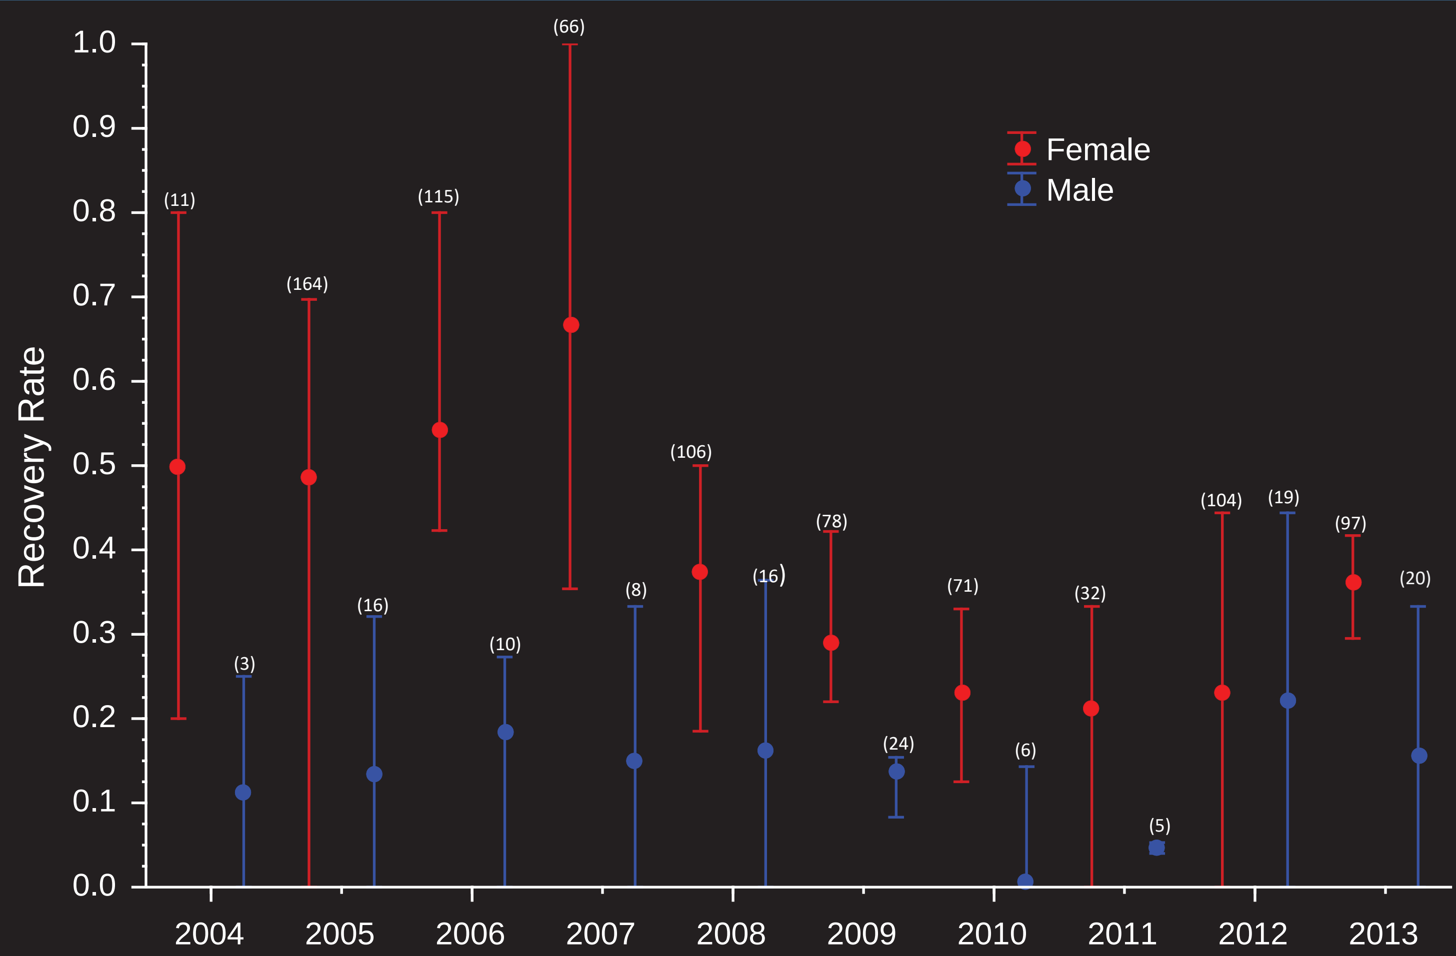
Median recovery rates by tributary



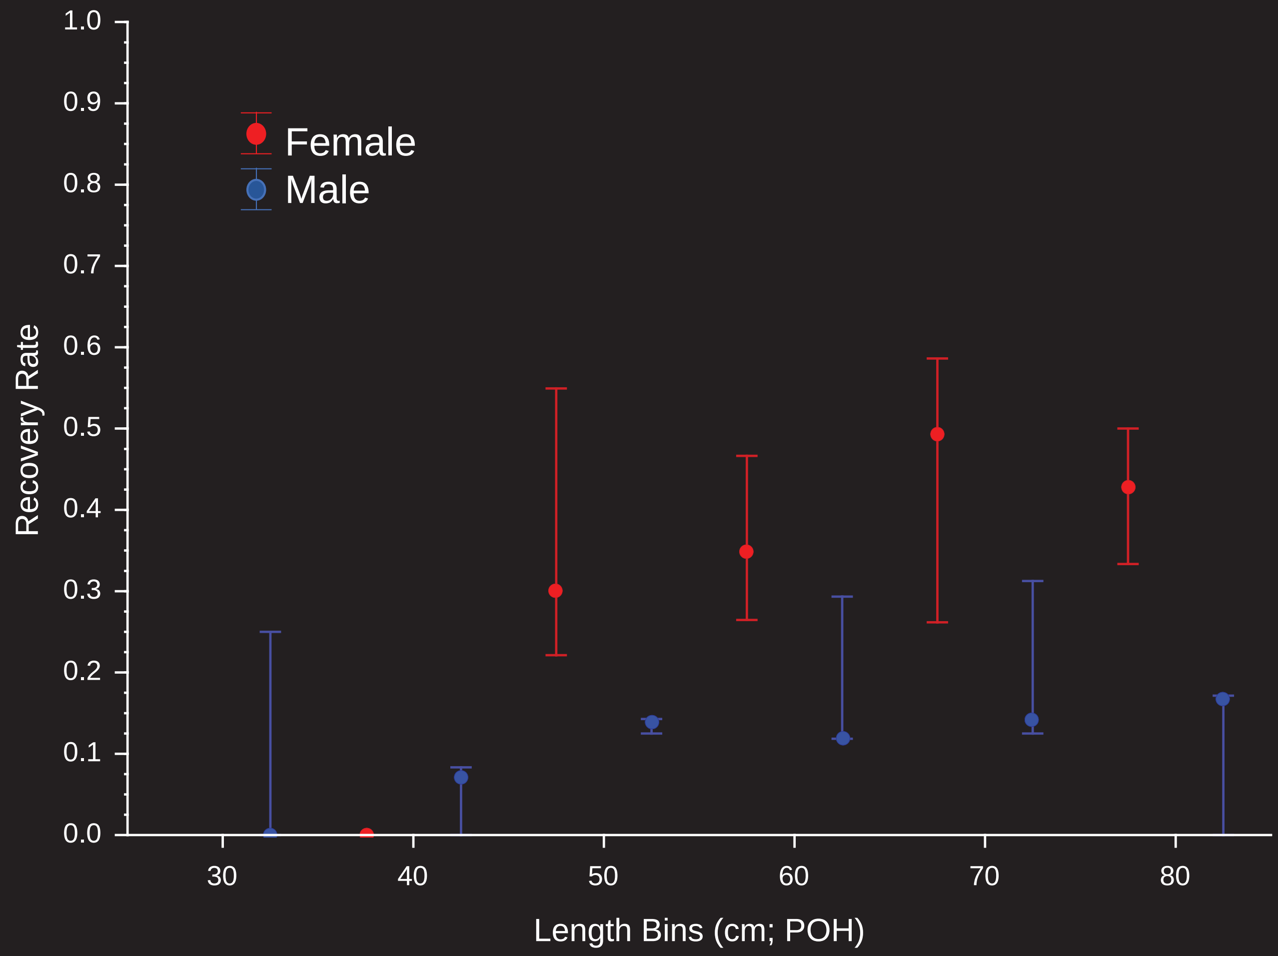
Recovery rates by channel type



Recovery rates by year & sex



Recovery rates by length and sex



Factors that influence recovery rates

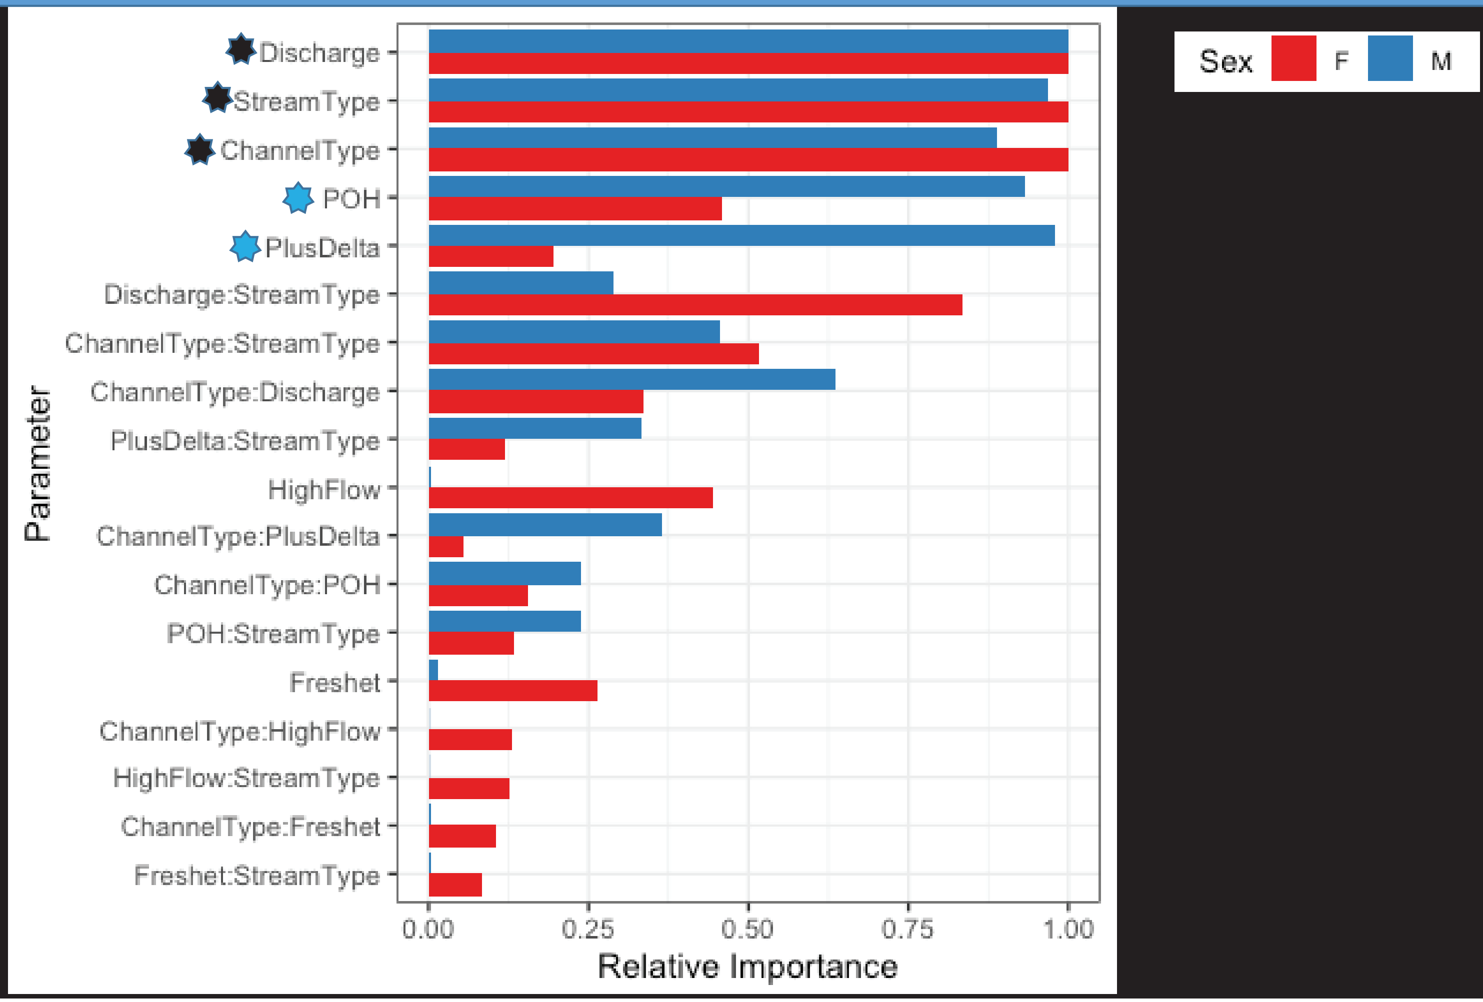
Environmental characteristics

- River discharge:
  - Year-to-year variation:
    - Mean discharge
  - Within year variation:
    - Number of freshet events flow increased by greater than 10%
    - Number of days flows elevated by greater than 20%
    - Number of days flows increased relative to the prior day
- Stream characteristics:
  - Glacial and non-glacial streams
- Channel type:
  - Pool-riffle and plane-bed reaches

Fish characteristics

- Sex: spawning behaviors
- Fish size: carcass detection and movement
- Origin: Size differences and differential spawning distributions

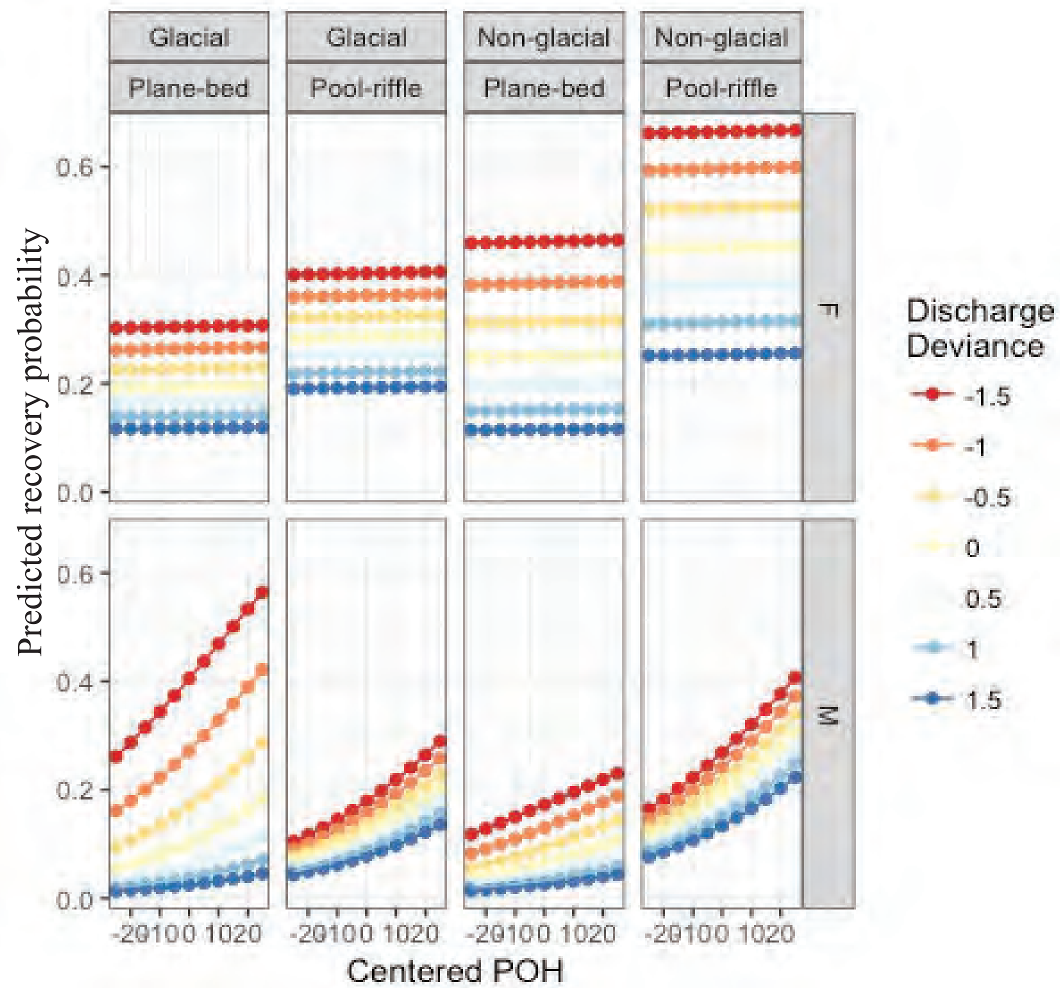
Binomial GLM with logit Link separately by sex: Importance of variables within Models



Predicated recovery probabilities

Recovery probabilities for both sexes were:

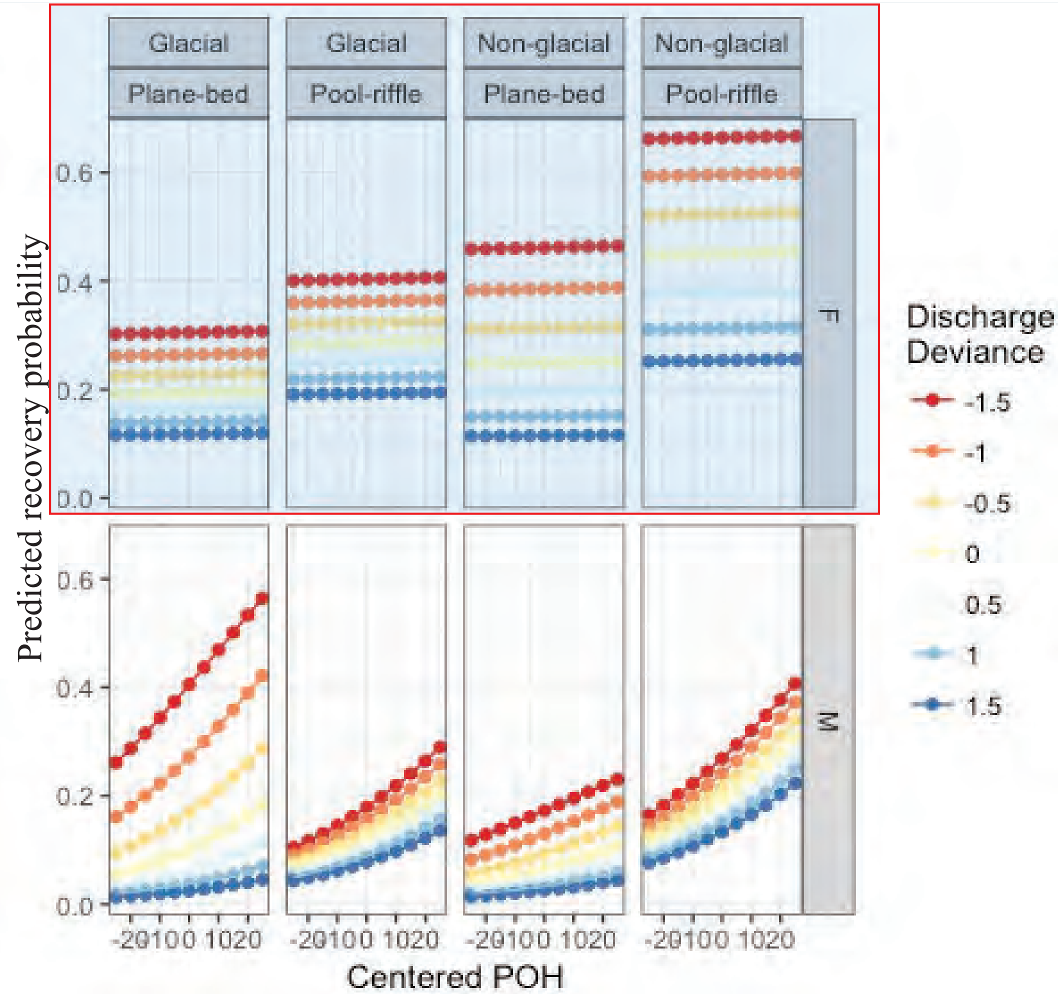
- Lower in years were discharge was higher
- Lower in glacial streams relative to non-glacial streams
- Lower in plane-bed channels compared to pool-riffle



Predicated recovery probabilities

Female recovery probabilities:

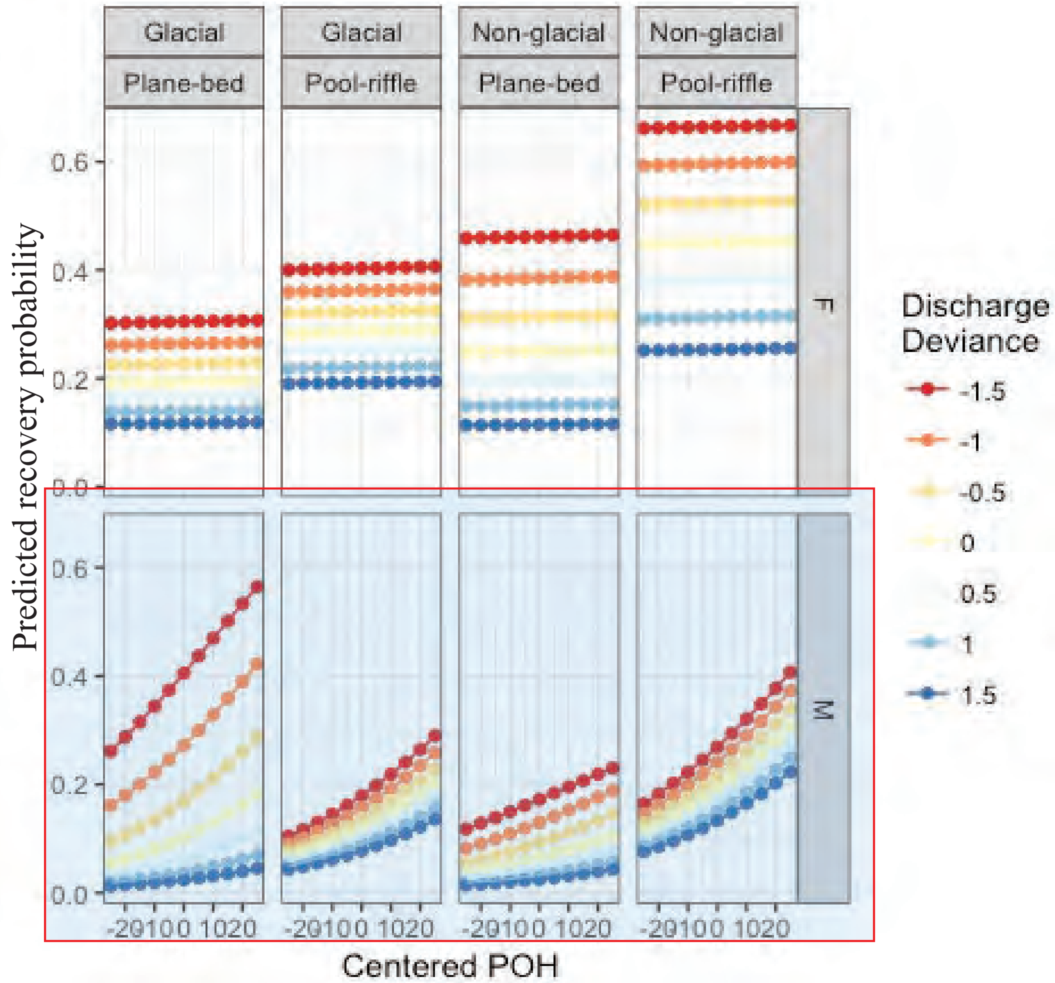
- POH had very little effect on recovery
- Interaction between discharge and stream-type
  - Lower in years were discharge was higher,
  - But decreased at a greater rate in non-glacial stream
- Additionally, recoveries decreased as the number of days that flows were elevated (>20%) increased



Predicated recovery probabilities with modeled average coefficients

Male recovery probabilities were:

- Higher for larger-sized males
- Additionally, recoveries were lower as the number of days discharge increased



Corrected vs non-corrected recoveries: 2011

Sex	Age	Carcass recoveries		Bias (%)
		Observed	Corrected	
Male	3	30	50	-67
	4	21	16	24
	5	31	16	48
Female	3	3	4	-33
	4	44	44	0
	5	34	33	3

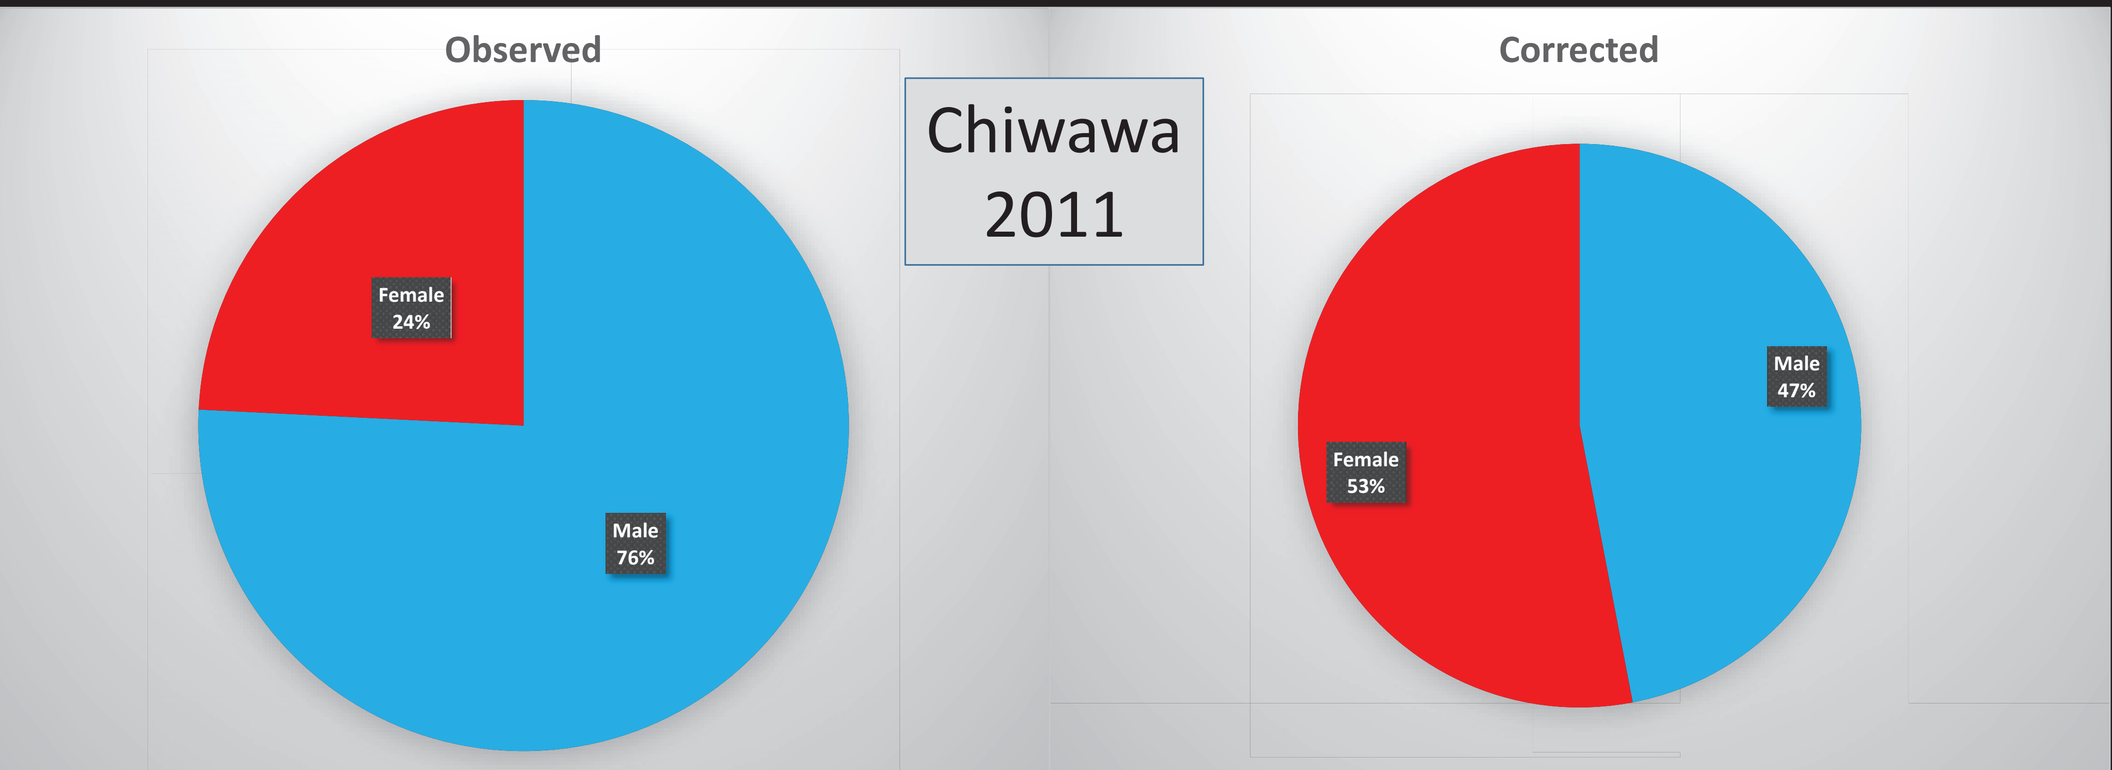
Corrected vs non-corrected recoveries: 2013

Sex	Age	Carcass recoveries		Bias (%)
		Observed	Corrected	
Male	3	39	53	-36
	4	70	62	11
	5	16	10	38
Female	3	4	4	0
	4	200	202	-1
	5	43	41	5

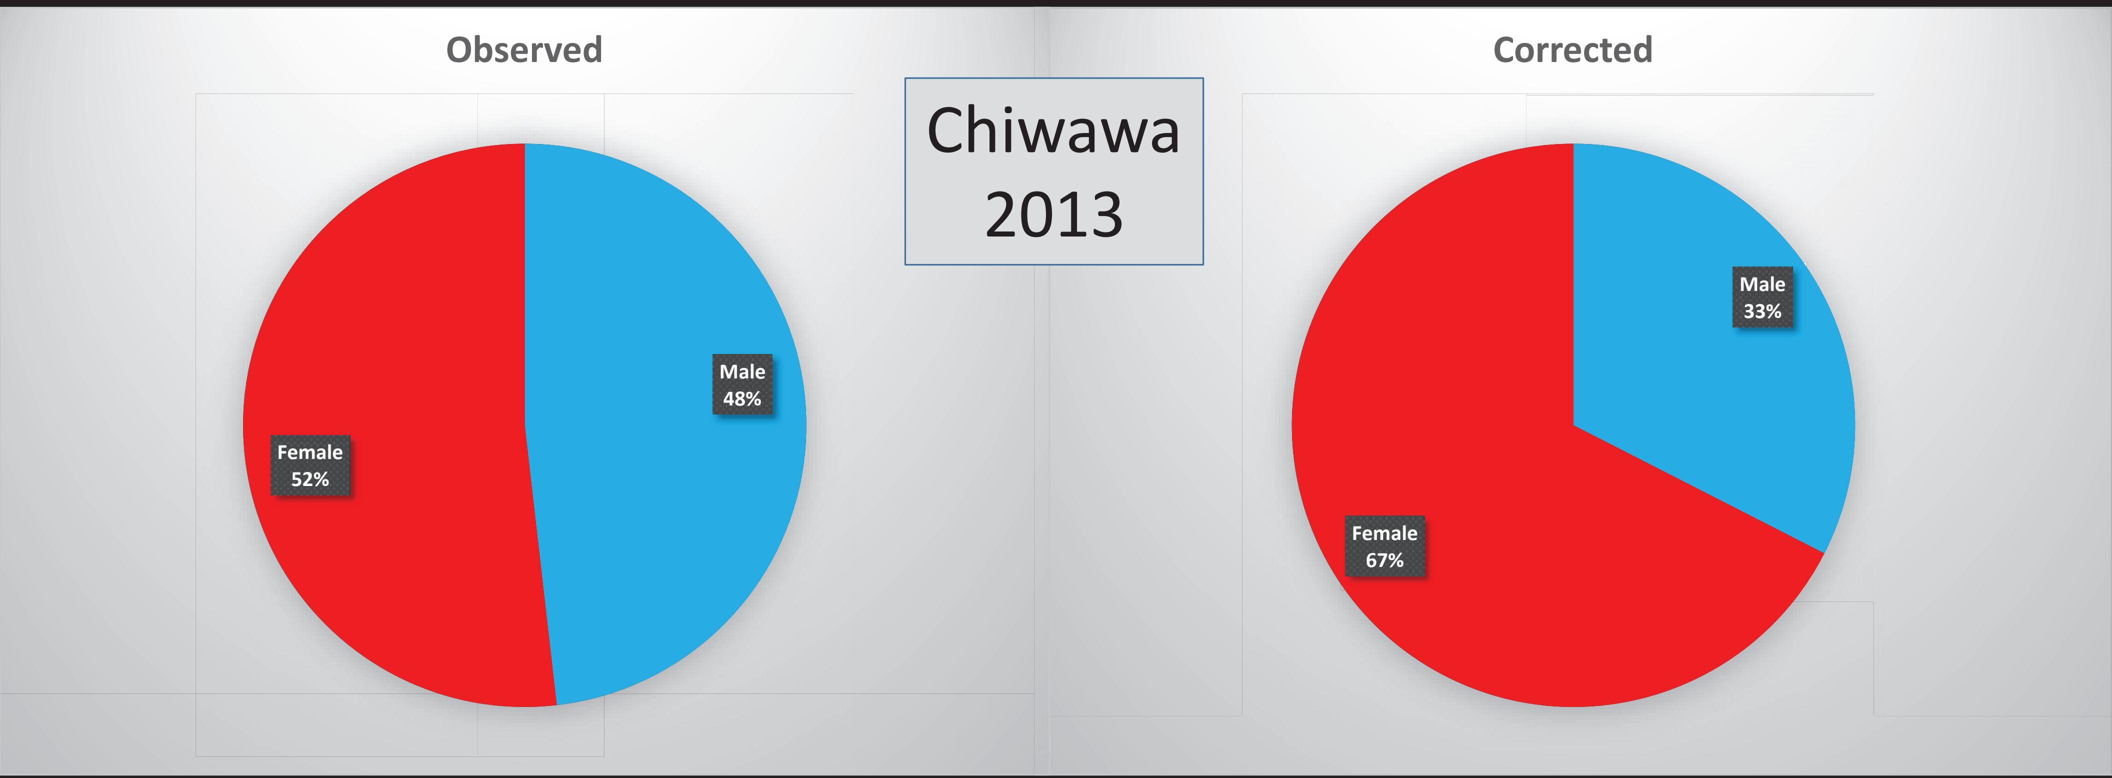
Fish per redd and spawning abundance

Year	Metric	Tumwater Ratio	Observed Carcasses	Corrected Carcasses by Channel Type	
				Plane Bed	Pool Riffle
2011	Fish per redd	4.13	2.01	4.10	1.26
	Redd count	474	474	104	370
	Spawner Abundance	1,958	953	894	
2013	Fish per redd	1.93	2.01	1.68	1.43
	Redd count	687	687	142	545
	Spawner Abundance	1,326	1,381	1,018	

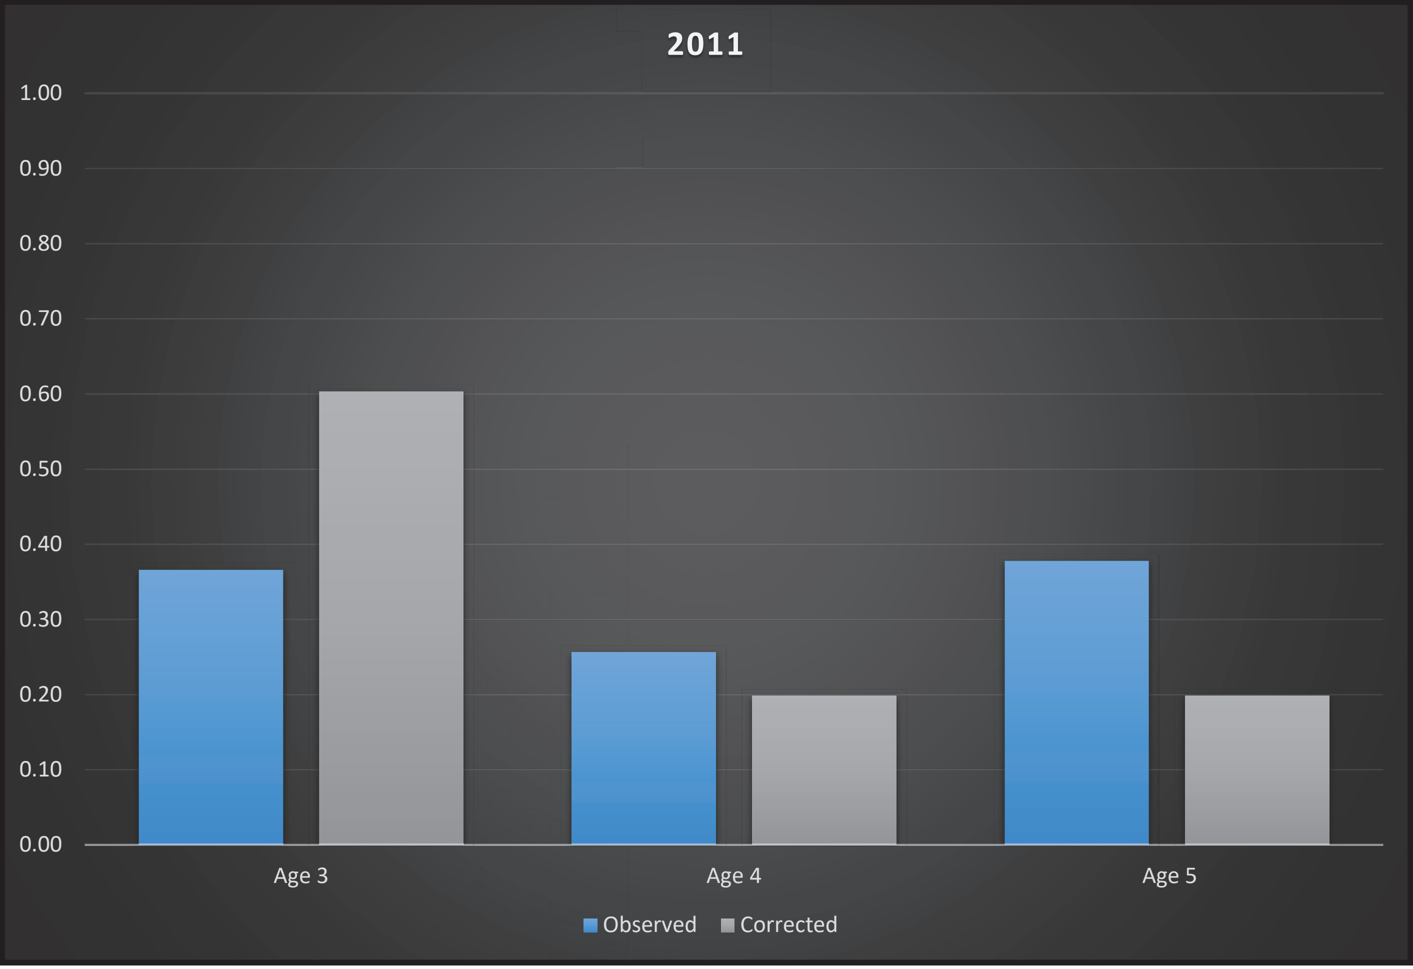
Sex ratios: estimated spawning abundance



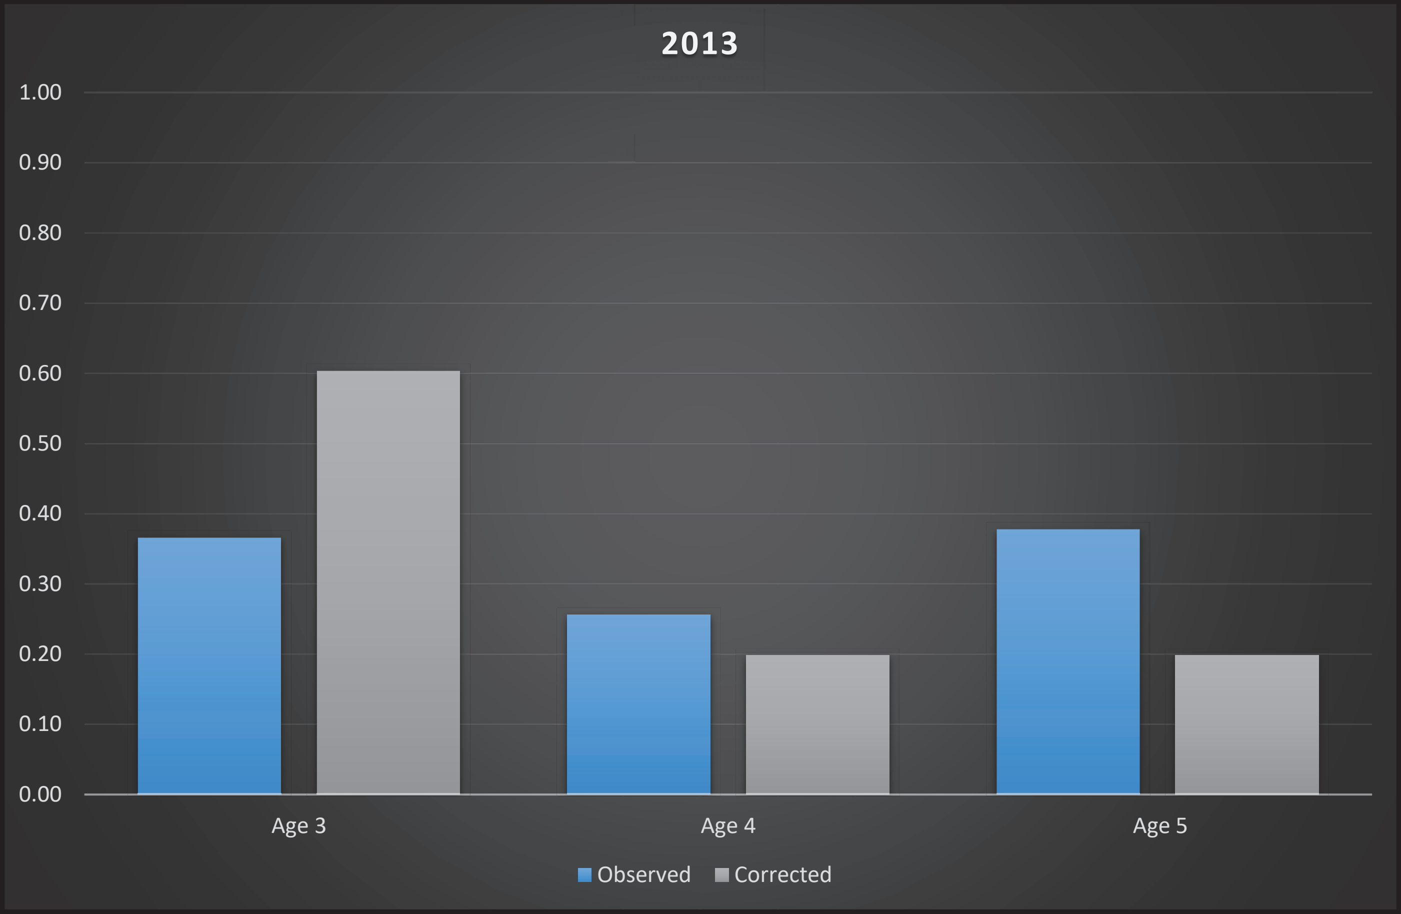
Sex ratios: estimated spawning abundance

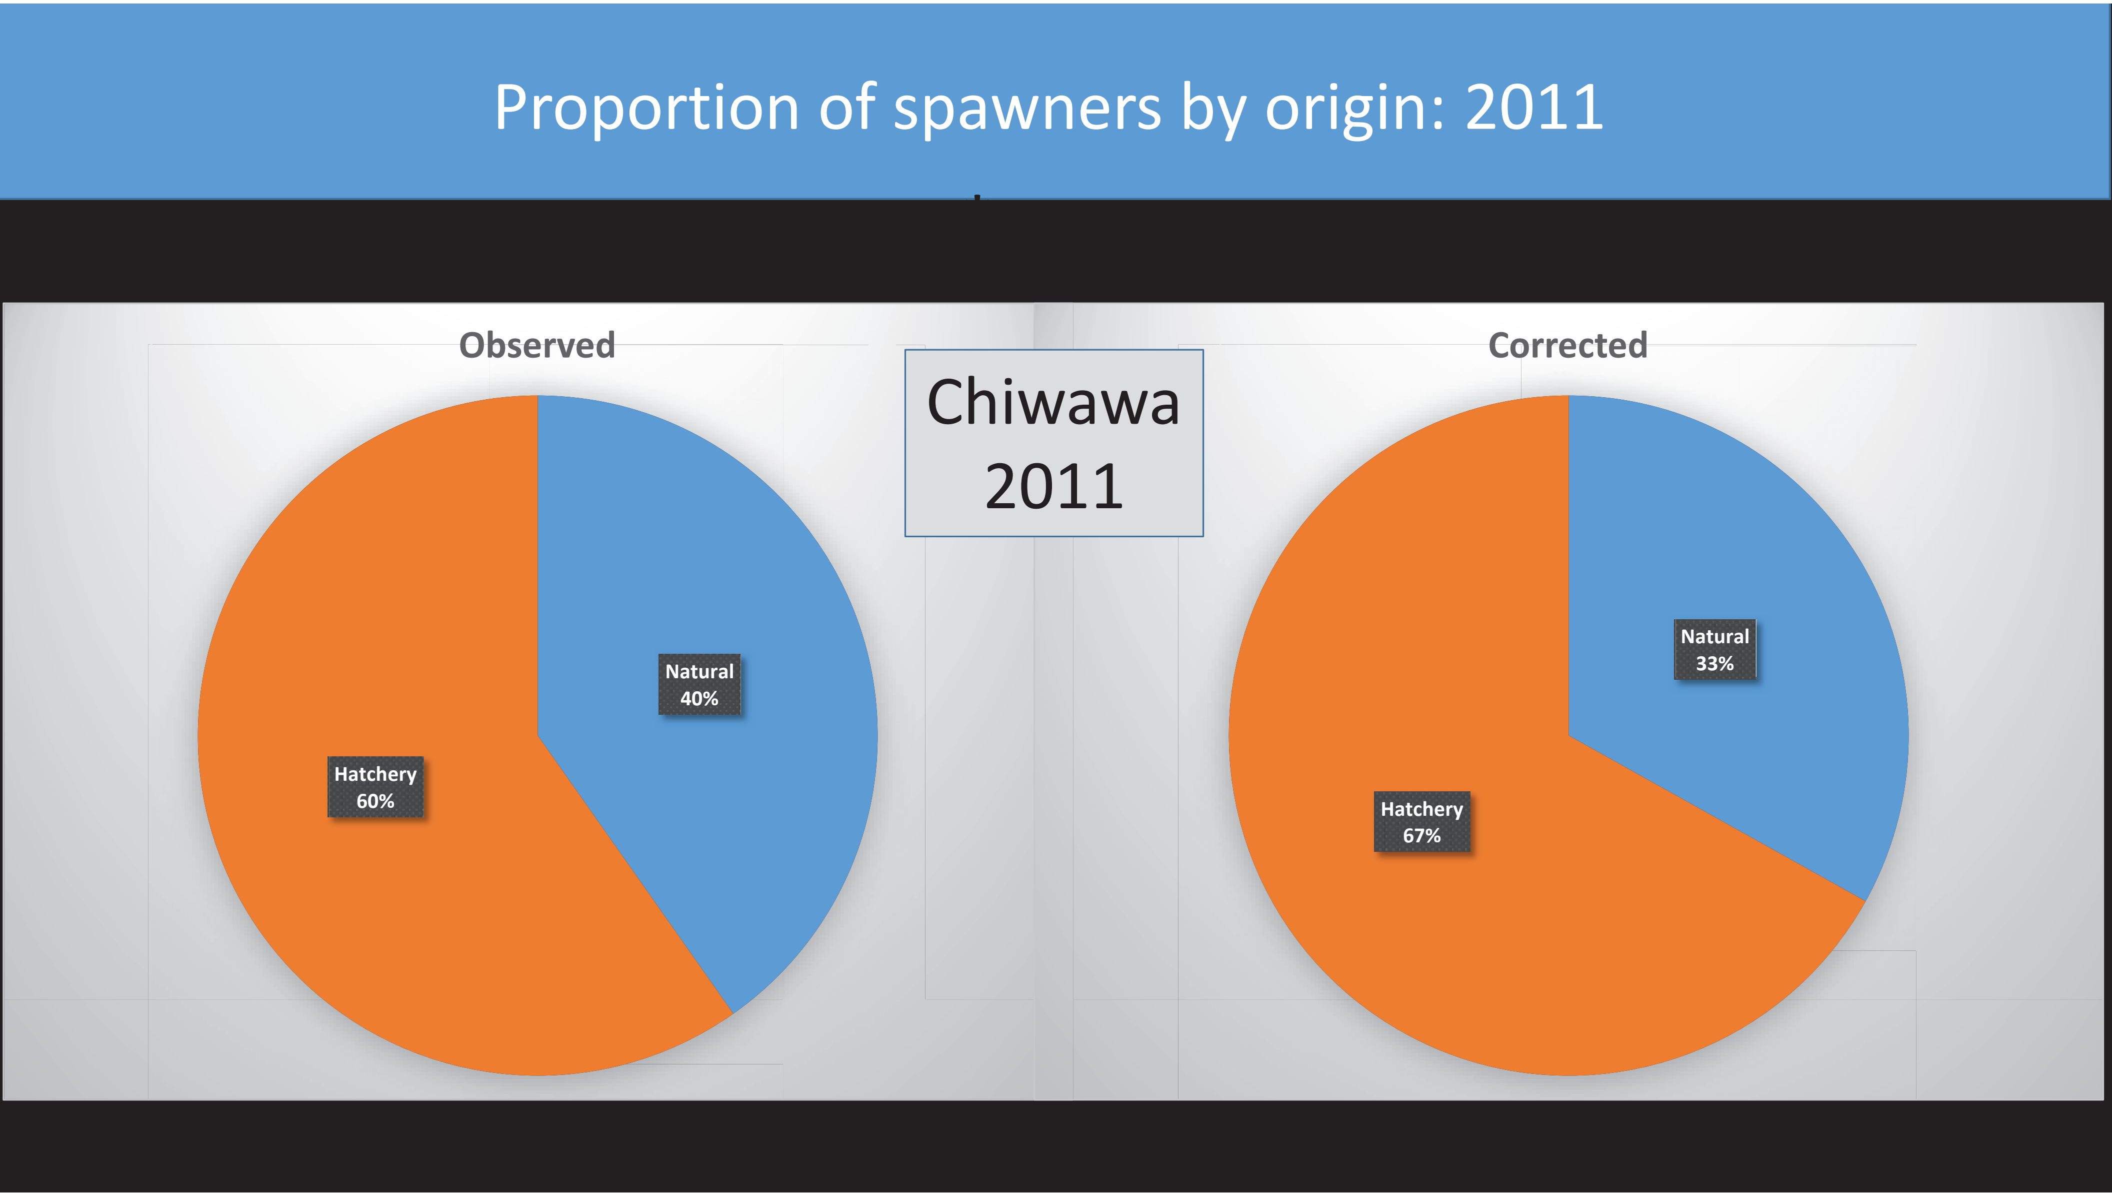


Male Ages: estimated spawning abundance



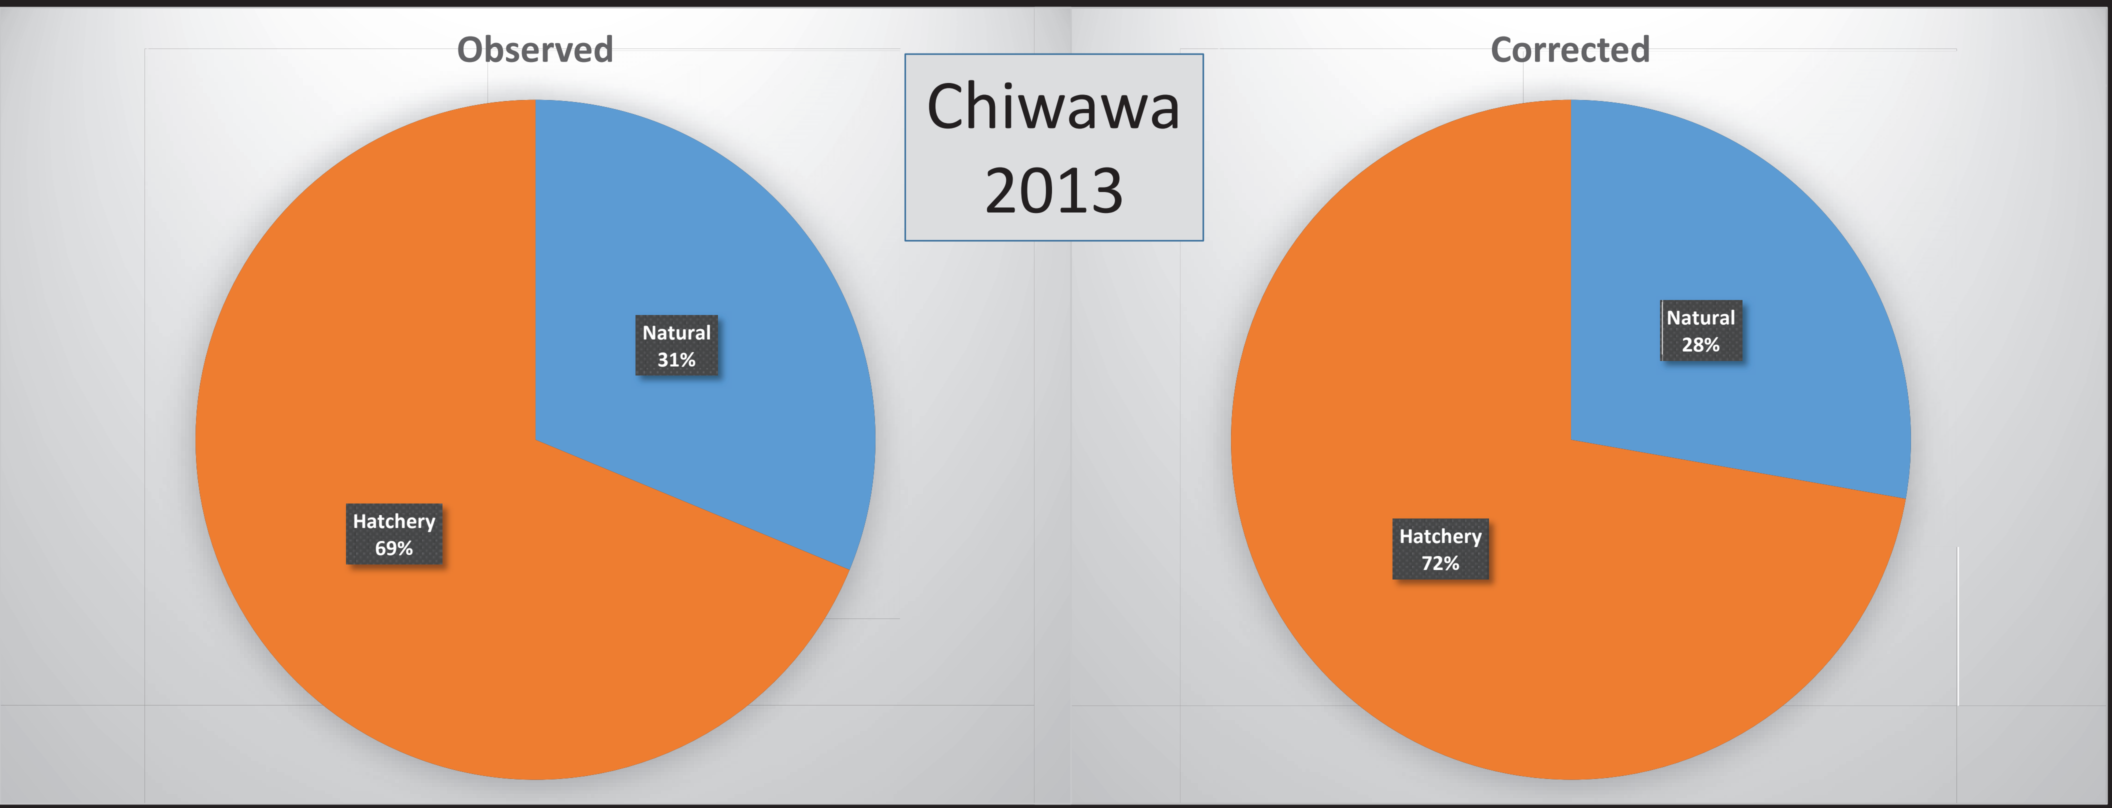
Male Ages: estimated spawning abundance





Proportion of spawners by origin: 2011
Observed
Chiwawa 2011
Corrected
Natural 40%
Hatchery 60%
Natural 33%
Hatchery 67%

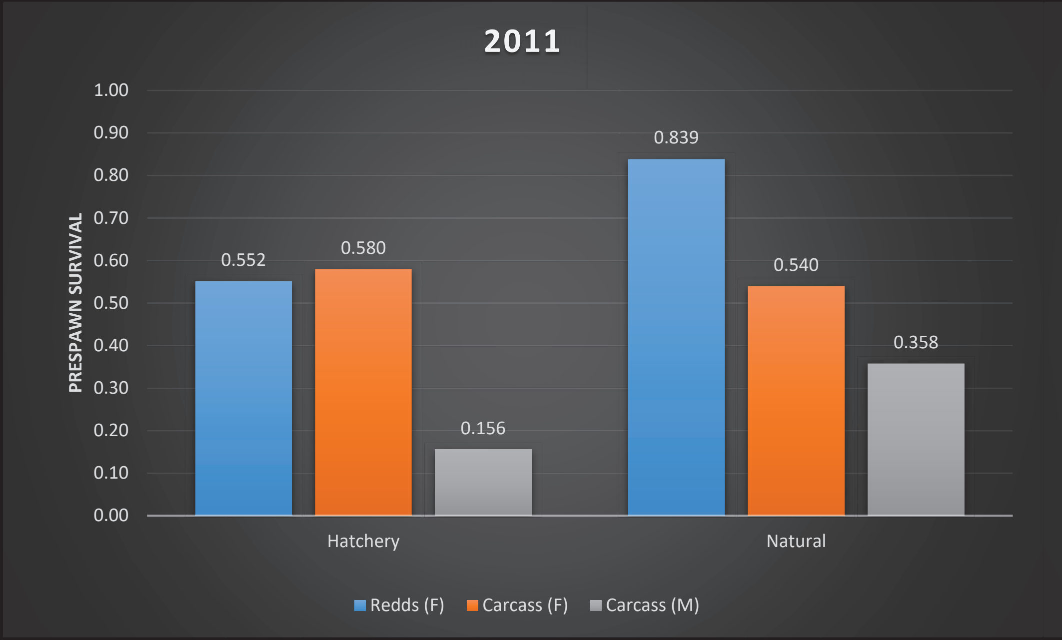
Proportion of spawners by origin

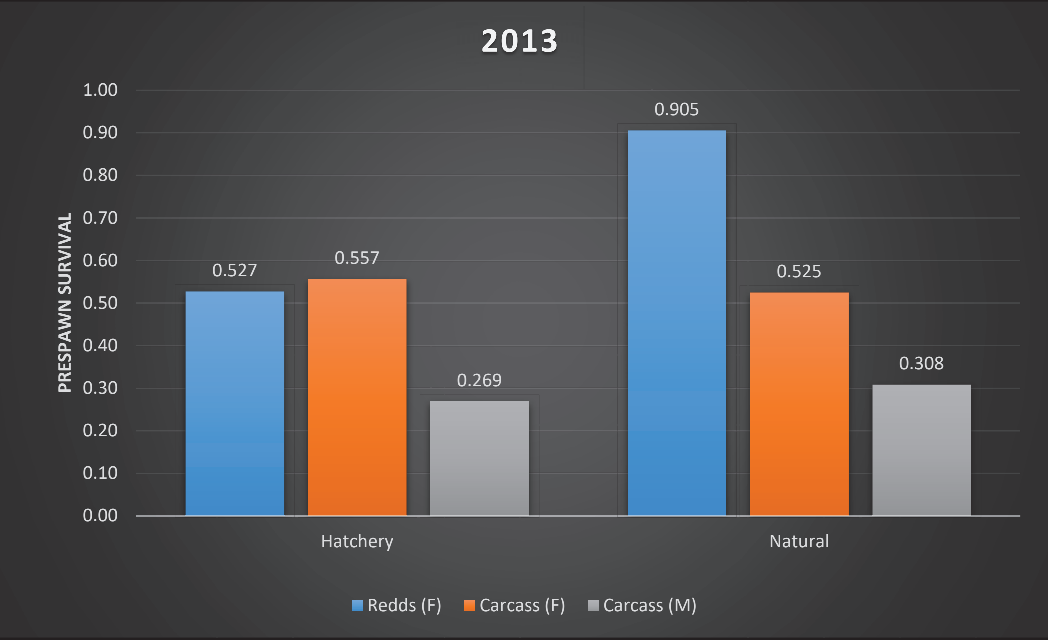


Take Home

- Carcasses often times are the only method for reconstructing a spawning population
- Observed carcass recoveries are biased toward recovering a greater proportion of females and larger-sized males
- This may be of concern when you have differences in body size and spawning distributions between hatchery and natural spawning fish
- Over-estimating abundance and survival of natural spawning fish and/or over representing older age classes

Prespawn Survival





Objectives

- Generate unbiased estimates of spawner escapement with uncertainty
- Develop methods that are transferable and usable by others

Spring Chinook Spawning Escapement

- Old Methods 1.0 (Murdoch et al. 2010)
  - Did not account for observer error (negative bias)
  - No measure of uncertainty
  - Used the same FPR from stock assessment (prespawn) for all streams (unknown bias)
  - Carcass bias included prespawn mortality (unknown bias)
- New method 2.0 (Murdoch et al. in review)
  - GAUC for redds
  - Used the same FPR from stock assessment (prespawn) for all streams (unknown bias)
  - Carcass bias included prespawn mortality (unknown bias)

Spring Chinook Salmon 3.0

1. Conduct weekly redds and carcass surveys
   - New redds from 0 to 0. GPS every redd.
   - Carcasses = 20% per reach…more is better. GPS every carcass.
2. Estimates redds using GAUC (Murdoch et al. in review)
   - Experience, Thalweg CV and redd density
3. Remove bias from carcass sample (Hughes et al. in prep)
   - Assign channel type for each carcass using GPS of carcass
   - Carcass location = spawning location (Murdoch et al. 2010)
   - Estimate stream and channel type specific sex ratio
   - Sex ratio = FPR assuming 1 redd per female (Murdoch et al. 2009)
4. Estimated redds x FPR = Number of spawners by channel type
5. Corrected carcass sample x spawners = H and W spawner abundance ± SE

Steelhead Spawning Escapement

- Old Methods 1.0
  - Did not account for observer error (negative bias)
  - No measure of uncertainty
  - Used the same FPR from stock assessment (prespawn) for all streams (unknown bias)
- New method 2.0 (Murdoch et al. in 2018)
  - GAUC for redds
  - Used the same FPR from stock assessment (prespawn) for all streams (unknown bias)

Steelhead 2.0 (Redd only)

1. Conduct weekly redd counts of all index areas
   - New redds from 0 to 0. GPS every redd.
   - Single peak count of non-index areas
2. Estimate redds using GAUC (Murdoch et al. 2018)
   - 1 or 2 person models and similar covariates
3. Estimate sex ratio (i.e. FPR) from stock assessment data
   - Adjust for harvest and harvest impacts
   - Adjust for broodstock and adult management
   - Adjust for differential prespawn mortality (Fuchs et al. in prep)
4. Estimated redds x FPR = spawners
5. Adjusted stock assessment data x spawners = H and W spawners

Steelhead 3.0 (PIT/Redd Hybrid)

1. Conduct weekly redd counts of mainstem index reaches
   - New redds from 0 to 0. GPS every redd.
   - Single peak count of non-index areas
2. Estimate redds using GAUC (Murdoch et al. 2018)
   - 2 person models
3. Estimate sex and origin ratios from PIT tag data (i.e. FPR)
   - Using PIT tag not assigned to tributaries
4. Estimated mainstem redds x FPR x H/W = H and W spawners
5. Estimate tributary spawner using model (Waterhouse et al. in prep)
6. Add Mainstem and tributary spawners = Population ± SE
   - Origin, sex, length and age derived from PIT data (i.e., R/S)

Comparison of methods

- Spring Chinook (Wenatchee, Entiat and Methow)
  - 1.0: Negatively biased (Redds and FPR)
  - 2.0: Negatively biased (FPR)
  - 3.0: Unbiased or least biased
- Steelhead
  - Entiat are spring run fish (Waterhouse et al. in prep)
  - Methow and Wenatchee
    - 2.0 or 3.0
  - Okanogan
    - 3.1 – PIT for tribs; mainstem (under review). Could try GAUC.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: May 15, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the April 17, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

---

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, April 17, 2019, from 9:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Tracy Hillman will review aspects of the Independent Scientific Advisory Board's *Review of Spring Chinook Salmon in the Upper Columbia River* under HCP-HCs' purview (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing.)*
- Catherine Willard will update the genetics section of the *Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan)* based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*

- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will confirm with Andrew Murdoch that Wenatchee spring Chinook salmon DNA sampling of the 2018 to 2023 returns is still consistent with the original Relative Reproductive Success Study extension agreement and provide an update to the extension. (Item I-A) *(Note: this item is ongoing.)*
- Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A). *(Note: this item is ongoing.)*
- Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding topics for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols (Protocols) (Item I-A). *(Note: this item is ongoing.)*
  - Use of age-3 males in broodstock
  - Use of alternative, non-random mating strategies
  - Establishing ranges around broodstock collection targets
  - Source for Chiwawa spring Chinook salmon broodstock
- Tracy Hillman and Larissa Rohrbach will add review of the Protocols to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item II-A). *(Note: this item is ongoing.)*
- Brett Farman will ask Amilee Wilson and Craig Busack (National Marine Fisheries Service [NMFS]) to clarify the intent of the direction provided in NMFS Biological Opinions (BiOps) for marking Chiwawa and Nason conservation programs juvenile spring Chinook salmon (Item II-A).
- Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service [USFWS]) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to Winthrop National Fish Hatchery to inform a translocation discussion during the April 17, 2019 HCP-HCs meeting (Item II-C). *(Note: this item is ongoing.)*
- Mike Tonseth will revise and redistribute the 2017 *Out-planting Surplus Methow Composite Spring Chinook Salmon Adults* memorandum for review and discussion during the May 15, 2019 HCP-HCs meeting (Item II-C).
- Deanne Pavlik-Kunkel will provide Grant PUD's approval of routine distribution of merged PRCC HSC and HCP-HC meeting materials according to the revised meeting protocols (Item II-E).
- Once approved by the HCP-HCs and PRCC HSC, Tracy Hillman will present the revised merged HCP-HC and PRCC HSC distribution list to the HCP-CC for approval (Item II-E).

Wells HCP Hatchery Committee

- Greg Mackey will provide a revised version of Douglas PUD's draft 2019 M&E Implementation Plan for HCP-HC approval by email (Item I-A). (*Note: this item is ongoing.*)

PRCC Hatchery Subcommittee

- Todd Pearsons will finalize the PRCC HSC-approved 2019 Priest Rapids Hatchery M&E Implementation Plan for distribution (Item III-B).
- HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item III-C).

Decision Summary

- The Rock Island HCP-HC and PRCC HSC Parties approved the proposed marking scheme for Chiwawa and Nason Conservation Program fish based on program assignment and parental origin (Item II-A). Chelan PUD, Grant PUD, USFWS, WDFW, CCT, NMFS, and the Yakama Nation (YN) approved during the meeting on April 17, 2019. Grant PUD provided their vote in an email by Tuesday April 23, 2019, with the following three contingencies:
  - It only applies to the brood year 2019 of the Nason Conservation Program until further information is provided (it does not apply to the brood year 2018 Nason Conservation Program because no hatchery by hatchery [HxH] crosses were necessary).
  - It is necessary to mark fish within the conservation portion of the program separately (e.g., if matings are mixed such as hatchery by wild [HxW] or if all crosses are wild by wild [WxW], then an additional tag may not be necessary).
  - Adequate risk management occurs to ensure that a caudal peduncle mark will not injure fish.
- The PRCC HSC approved the 2019 Priest Rapids Hatchery M&E Implementation Plan in today's meeting (Item III-B).

Agreements

- HCP-HCs and PRCC HSC will review the current broodstock collection protocols in September and October to identify changes needed in the next Protocols and determine who will make the revisions (Item II-B). Topics that deserve further discussion and/or Statements of Agreement (SOAs) will be identified on a case-by-case basis.
- The HCP-HCs and PRCC HSC will distribute draft materials only to a primary distribution list that includes representatives, alternates and select participants (Item II-E). Final materials will be sent to a broader/secondary distribution list.

Review Items

- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on April 18, 2019, notifying them that the SOA on development of annual broodstock collection protocols is available for review (Item II-B).

- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on April 18, 2019, notifying them that the updated meeting protocols, distribution lists, and draft Conflict of Interest SOA are available for review (Item II-E).

Finalized Documents

- Mike Tonseth informed Brett Farman and Charlene Hurst of the formal submission of the HCP-HCs, PRCC HSC, and Wells HCP-CC approved final 2019 Upper Columbia River Broodstock Collection Protocols to NMFS on March 28, 2019.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the March 11 Conference Call Minutes and March 20, 2019 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and asked for any additions or changes to the agenda. No changes to the agenda were requested.

The HCP-HCs and PRCC HSC representatives reviewed the revised draft March 11 conference call and March 20, 2019 meeting minutes. Larissa Rohrbach said there were some revisions that the representatives then reviewed. The HCP-HCs and PRCC HSC representatives approved the draft March 11 conference call and March 20, 2019 meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on March 20, 2019, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on March 20, 2019)*:

Joint HCP-HCs and PRCC HSC Topics

- *Tracy Hillman will review aspects of the Independent Scientific Advisory Board's (ISAB) Review of Spring Chinook Salmon in the Upper Columbia River under HCP-HCs' purview (Item I-A).* Hillman said this item is ongoing; he is working on statistical analysis for BACI designs, then will switch to reviewing the Independent Scientific Advisory Board material.
- *Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Fish Hatchery (Item I-A).* Mackey said this item is ongoing; he will provide a presentation to the HCP-HCs in an upcoming meeting.
- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A).*
  Tonseth said this item is ongoing pending information that will refine the analysis.

- *Catherine Willard will update the genetics section of the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan) based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A).*
  Willard said this item is ongoing.
- *Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow FH programs (Item I-A).*
  Truscott said this item is ongoing.
- *Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating the proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A).*
  Farman said this item is ongoing. Farman said the end result would be a higher PNI than the current targets and asked whether this action item is still relevant. Bill Gale said the multi-population model for PNI provides a more accurate estimation of PNI and if this is being used for other stocks it should be used for the Nason and Chiwawa programs. Farman asked if it is relevant to the current program management. Gale said it might be helpful for NMFS to provide their approval of the use of this tool for the future. Farman agreed to retain the action item.
- *Brett Farman will inform the HCP-HCs of the publication date for public review of the Methow River Steelhead Environmental Assessment (Item II-D).*
  Farman said this item is complete; Larissa Rohrbach forwarded the link to the published plans following the meeting on April 17, 2019.
- *Brett Farman will inform the HCP-HCs on the publication date for public review of the Section 10 permits for the unlisted Chinook salmon bundle (Item II-D). (Note: Larissa Rohrbach distributed an email from Farman and draft permits for the Section 10 programs to the HCP-HCs and PRCC HSC on March 28, 2019.)*
  Brett Farman said this item is complete.
- *Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service [USFWS]) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to Methow Hatchery and Winthrop National Fish Hatchery (WNFH) to inform a translocation discussion during the April 17, 2019 HCP-HCs meeting (Item I-C).*
  Tonseth and Bill Gale said this item is ongoing.
- *Mike Tonseth will revise and redistribute the 2017 Out-planting Surplus Methow Composite Spring Chinook Salmon Adults memorandum for review and discussion during the April 17, 2019 HCP-HCs meeting. (Item II-C)*
  This item will be discussed in today's meeting. Tonseth said a revised version will be distributed in the coming weeks.

- *Mike Tonseth will confirm with Andrew Murdoch that Wenatchee Spring Chinook DNA sampling of the 2018 to 2023 returns is still consistent with the original Relative Reproductive Success (RSS) Study extension agreement and provide an update to the extension. (Item I-A).*
  Tonseth said this item is ongoing.
- *Mike Tonseth will convene a Joint Fisheries Parties meeting to discuss marking to identify hatchery x hatchery returns from fish used to backfill the Nason and Chiwawa conservation programs (Item II-A).*
  Tonseth said a meeting of the Joint Fisheries Parties (JFP) was held on April 15, 2019, and this item is complete.
- *Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A).*
  Tracy Hillman said this item is ongoing.
- *Tracy Hillman and Larissa Rohrbach will maintain the following list of outstanding topics for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols (Protocols) (Item I-A).*
  - *Use of age-3 males in broodstock*
  - *Use of alternative, non-random mating strategies*
  - *Establishing ranges around broodstock collection targets*
  - *Source for Chiwawa spring Chinook salmon broodstock*

  Hillman said this item is ongoing. Greg Mackey said he will present on use of age-3 males in broodstock at an upcoming meeting.
- *Tracy Hillman and Larissa Rohrbach will help the HCP-HCs and PRCC HSC identify co-authors and opportunities to make revisions to the Protocols in advance of 2020 deadlines (Item I-A).*
  This item will be discussed in today's meeting.
- *Greg Mackey will send suggested language on broodstock protocols for the Douglas PUD coho salmon program to Keely Murdoch and Cory Kamphaus (Yakama Nation [YN]) for approval and to Mike Tonseth for inclusion into the 2019 Protocols by end of day March 20, 2019 (Item I-A). (Note: language was incorporated into the 2019 Protocols that were distributed by Larissa Rohrbach on March 21, 2019.)*
  Tracy Hillman said this item is complete.
- *Mike Tonseth will email a final draft of the 2019 Protocols to Larissa Rohrbach for distribution to the HCP-HCs and PRCC HSC by end of day March 21, 2019 (Item I-A) (Note: the 2019 Protocols were distributed by Rohrbach via email on March 21, 2019.)*
  Tracy Hillman said this item is complete.
- *HCP-HCs and PRCC HSC representatives or alternates will vote by email whether to approve the 2019 Protocols by end of day March 22, 2019 (Item I-A). (Note: the 2019 Protocols were*

approved by the Wells, Rock Island, and Rocky Reach HCs and the PRCC HSC Parties by email on March 22, 2019.)
Tracy Hillman said this item is complete.

Wells Hatchery Committee

- *Greg Mackey will provide a revised version of Douglas PUD's draft 2019 M&E Implementation Plan for HCP-HC approval by email (Item I-A).*
  Mackey said this item is ongoing.

Rock Island and Rocky Reach HCP Hatchery Committee

- *Mike Tonseth will email the Hatchery and Genetic Management Plans (HGMPs), biological opinions (BiOps), and permits that give direction on marking spring Chinook salmon in the Chiwawa and Nason conservation and safety-net programs to Larissa Rohrbach for distribution to the HCP-HCs and PRCC HSC and filing on the Extranet site (Item II-A). (Note: Relevant documents were distributed and filed by Rohrbach on March 21, 2019).*
  Tracy Hillman said this item is complete.
- *Mike Tonseth will confirm the timeline for tagging juvenile Chiwawa spring Chinook salmon in 2019 (Item II-A).*
  Tonseth said this was discussed in the JFP meeting; tagging will occur the week of May 6, 2019.
- *Brett Farman will ask Amilee Wilson and Craig Busack (National Marine Fisheries Service [NMFS]) to clarify the intent of the direction provided in NMFS BiOps for marking Chiwawa and Nason conservation program juvenile spring Chinook salmon (Item II-A).*
  Farman said this item is ongoing. This item will be discussed in today's meeting.

PRCC Hatchery Subcommittee

- *Tracy Hillman will ask the PRCC to provide specific instructions in writing regarding what they want the PRCC HSC to do with the White River spring Chinook salmon hatchery memorandum (Item V-C). (Note: Hillman sent an email to the PRCC Chair regarding this topic.)*
  Hillman said this item is complete. Hillman confirmed that the PRCC Facilitator has shared this information with the PRCC.
- *PRCC HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item V-C).*
  Hillman said this item is ongoing.

II. Joint HCP-HCs and PRCC HSC

A. DECISION: Tagging Chiwawa/Nason Conservation Program Spring Chinook Salmon

Mike Tonseth said the Joint Fisheries Parties (JFP) met on Monday, April 15, 2019. He said that the issues that the JFP deals with include making sure programs are consistent with permit terms and conditions, US v Oregon, and management plans.[1] The JFP came up with an interim fish marking solution that balances the programmatic needs to incorporate the offspring of HxH crosses into the conservation program (to meet program target numbers). The solution is to add a secondary tag that differentiates the offspring of HxH crosses (HxH fish) from offspring of WxW crosses (WxW fish).

The JFP agreed that the HxH fish used to satisfy the shortfall in the number of conservation program fish will be tagged with coded wire tags (CWT) in the snout, blank wire tags (BWT) in the caudal peduncle, and will be ad-present (adipose fin unclipped); HxH fish snout wire CWT will have a different code than the WxW fish. Tonseth said the JFP recognizes this is not a preferable approach given the potential for injuries in the dorsal spine when injecting the caudal tag. Tonseth said all other HxH fish will be ad-clipped (adipose fin absent).

The proposed tagging scheme for all components of the Nason and Chiwawa conservation and safety-net programs was written on the white-board, summarized in the following table:

Number	Program	Origin	Adipose Mark	Snout Mark	Body Mark
144,000	Chiwawa Conservation	WxW	Ad +	CWT	None
		HxH	Ad +	CWT	Caudal BWT
123,000	Nason Conservation	WxW	Ad +	None	Dorsal CWT[a]
		HxH	Ad +	CWT	Caudal BWT
98,000	Nason Safety-Net	HxH	Ad -	CWT	None

Note:
a. Prior to 2016, Nason Conservation Program WxW fish were marked with a snout CWT and a caudal CWT

[1] Conditions include those stipulated under NMFS Biological Opinion Consultation number NWR-2013-9707 issued July 3, 2013, and reinitiated May 29, 2015; NMFS Permit numbers 18118 and 18121 issued July 3, 2013, and amended May 29, 2015; and the following Hatchery and Genetic Management Plans:

- Chelan County Public Utility District No. 1 and Washington Department of Fish and Wildlife (WDFW), 2009. *Hatchery and Genetic Management Plan (HGMP) Wenatchee Upper Columbia River Spring Chinook: Chiwawa Spring Chinook*. October 14, 2009.
- Colville Confederated Tribes, National Marine Fisheries Service, U.S. Fish and Wildlife Service (USFWS), WDFW, and Yakama Nation, 2010. *Wenatchee Basin Spring Chinook Management Plan*. November 4, 2010.
- Public Utility District No 2 of Grant County (Grant PUD), WDFW, and Yakama Nation, 2009. *Hatchery and Genetic Management Plan (HGMP) Upper Columbia River Spring-Run Chinook Salmon – Nason Creek Supplementation Program*. September 15, 2009.
- Grant County PUD, WDFW, USFWS, and Yakama Nation, 2009. H*atchery and Genetic Management Plan (HGMP) Upper Columbia River Spring-Run Chinook Salmon – White River Supplementation Program*. September 15, 2009.

Tonseth said this will allow the programs to prioritize WxW fish for spawning ground and safety-net programs. Keely Murdoch said this is the most parsimonious solution.

Catherine Willard asked if monitoring technicians will be able to tell the difference between the caudal and dorsal tags when handling adult fish? Tonseth said yes, in an adult fish the tags are far enough apart. Tonseth said the most important thing is to bring the snout CWTs back from carcass surveys to identify the differential codes and program. He said it can be noted in the field whether a fish is ad-clipped or ad-present, then whether it has a wire tag. Tonseth said when identifying adults during surveys there will be some overlap between Chiwawa program HxH fish and Nason program HxH fish, because they will both be marked ad-present and with caudal BWTs, but they will be differentiated by the snout codes. Murdoch said it will be helpful to note dorsal versus caudal tags when handling fish or carcasses during the spawning season.

Murdoch said there may be different ways of tagging in the caudal region that can minimize injuries. Tonseth intends to discuss tag placement with Chuck Aldrich (WDFW) to ensure techniques minimize injury to juveniles.

Peter Graf asked Tonseth to clarify if and how the JFP considered the guidance provided in the various permitting and management documents. Graf said the proposed tagging scheme seems inconsistent with the BiOp. Tonseth said there was not a safety-net program considered for the Nason program in the BiOp. Tonseth said another conflict was deference to the HGMPs and Spring Chinook Salmon Management Plan; he said the Management Plan has much more detail. Murdoch noted that the section where marking direction was given in the BiOp was in the proposed program, not in the terms and conditions section. Tonseth and Murdoch noted that the Spring Chinook Salmon Management Plan was cited as an addendum to the permits.

Bill Gale said a minimum number of Leavenworth Hatchery fish are tagged with CWTs to make escapement calculations (approximately 200,000 fish or 17% of the program). Todd Pearsons asked what the risk would be of picking up Leavenworth program adult fish (strays) at Tumwater Dam and mistaking them for Chiwawa or Nason fish (they could be confused with Nason safety-net fish during handling). Gale said less than 3% of the adult return of the 200,000 CWT tagged fish are observed going over Tumwater Dam. Matt Cooper said very few strays are observed on the spawning grounds. Gale said an analysis was done for the HGMP if people would like to see more detail. Pearsons said if a Nason fish loses its CWT, it would likely be removed at Tumwater Dam because it would be assumed to be a Leavenworth stray. Gale said that an ad-present fish without CWT observed at Tumwater Dam is more likely a Nason program fish that has shed its tag than a Leavenworth stray.

Pearsons said one topic he wrestles with is whether the work done to keep these populations separate will be a positive, or if the added handling will counteract the positive aspects. Murdoch said the scanning and handling would be the same (as with previous tagging schemes); for the conservation program fish the tag is in a different location (depending on origin; caudal versus dorsal body tag).

Graf said he has a broader question on the Nason program: if adult management is done for escapement goals that prioritize wild fish, then WxW fish, and then HxH fish, why is a separate designation needed for safety-net fish?

Murdoch said the main difference is the safety-net fish are ad-clipped and subject to the fishery. Graf asked if the concern is that not enough may make it back in low return years. Murdoch said yes, we are in the middle of considering reducing program sizes and Committee representatives will need to consider and agree to the direct use of safety-net fish in the conservation programs. Murdoch said the safety-net program also has a hierarchy for broodstock selection—the first choice is hatchery-origin conservation program fish (identified by snout CWT and caudal CWT) and then safety-net fish.

Pearsons asked if there was discussion in the Nason program about whether to blend the groups rather than segregate them by marking. That is, is it better to separate WxW fish from HxH fish, or better biologically to mix the progeny among the conservation program and safety-net program and go forward with the same total number of fish? Graf said this could be done by using wild females for both programs. Tonseth said no, this was not considered for the 2018 brood due to the expediency of the issue with the brood on hand. Gale noted sometimes these decisions are made on the spawning day; the priority should be that all wild fish are spawned no matter the sex or sex ratio on hand on a given spawning day. Gale said a fish with a wild parent should just be tagged as wild for simplifying spawning work in the hatchery. Gale said the goal should be to make as many wild crosses as possible. Tonseth said this conversation can be had in coming months as spawning does not occur until August. Tonseth agreed the WxW pairings should be prioritized but would want to review the permits, HGMPs, and Spring Chinook Management Plan again in case there is not continuity between documents.

Hillman asked whether the HCP-HCs and PRCC HSC are ready to vote on the proposed marking scheme. Pearsons said Grant PUD is not ready to vote. Tonseth said this marking scheme only affects the brood year 2018 Chiwawa conservation program (permit held by Chelan PUD only) since the Nason program has enough WxW to meet brood year 2018 conservation program targets, but this problem may occur for brood year 2019 for the Nason program. Tonseth said Chiwawa fish will be marked May 1, 2019. Gale said he would prefer to allow all members the time to review and vote by email for both brood years. Tonseth said this cannot wait for a vote to prepare for marking the Chiwawa program this year and requested that a vote be made as soon as possible.

Pearsons said Grant PUD wants more information before locking into a long-term approach to determine how frequently a caudal peduncle CWT could be necessary for marking HxH fish, because the success depends heavily on marking techniques. Gale said this scheme only locks the program into marking HxH fish and WxH would be marked as wild fish. Murdoch said the YN coho salmon program has used this caudal peduncle tagging technique without any injury.

Hillman called for a vote by the Rock Island HC on the proposed marking scheme for Chiwawa program brood year 2018 fish and brood year 2019 fish, and the Nason program brood year 2019 fish. Hillman said today's votes are contingent on Grant PUD's vote, which they will submit by end of day Tuesday. The marking scheme was approved in the meeting by Chelan PUD, YN, USFWS, CCT, WDFW, and NMFS. Grant PUD will provide a vote on the marking scheme for Nason program brood year 2019 fish by end of day Tuesday, April 23, 2019.

B. Broodstock Collection Protocols Development Timeline

Tracy Hillman introduced the topic of discussion and said the issue is that Mike Tonseth does most of the work that work could be more evenly shared among Representatives, and the existing drafting schedule does not provide enough time to discuss topics that may require more extensive discussion in the Committees. One option is for the permit holders to start developing the broodstock collection protocols (Protocols) in November. Run projections would not yet be available; however, many topics could be initiated earlier.

Todd Pearsons suggested going forward with the previous year's protocols as the default condition and it would be the responsibility of members to bring up potential changes and major issues early enough to start discussions ahead of drafting the actual protocols. Pearsons said there are a number of items that could be discussed before November without the need for run predictions. Pearsons said a topic that has major implications for a given program would be sponsored by a member and discussed within the Committees.

Bill Gale said the Protocols is the wrong vehicle for making some of the changes that have been proposed in draft Protocols. Some changes should not be viewed as a change to the Protocols but a change to a program that gets recorded in an SOA. Gale suggested having a discussion about what types of changes are appropriate for the Protocols and what are not, and said that marking and program size, for instance, are not an issue to bring forth in the Protocols. Greg Mackey agreed with both Pearsons' and Gale's points. Pearsons said the Protocols should not be the decision-making document. Gale said it is unfair for the responsibility of decisions to fall to Tonseth as he drafts the Protocols. Keely Murdoch agreed to the points raised, but also noted that developing the Protocols does act as a catalyst for raising issues to be discussed.

Hillman suggested revisiting the protocol earlier, in October or November, to determine whether there are unresolved issues. He also suggested discussion of a demarcation that would guide what should be raised to the level of an SOA. Mackey said if it's a deviation from the BiOp or permit that controls the program, an SOA is the vehicle for formal agreement. Mackey said there would be some judgement call on the level of importance (of a topic to require an SOA). Pearsons said with regards to an SOA, it seems that different Members or Committees have different sensitivities to what should be elevated to the level of an SOA and should be handled on a case-by-case basis. Catherine Willard agreed.

Gale said the Protocols should be viewed as a document that is a convenient source for annual broodstock collection, trapping, and geneflow management information, and useful as a living document. Gale said there should be separation of the information that could change annually.

Mackey said in the old Section 10 permits, it actually stated that WDFW should develop the Protocols annually. Mackey said the new approach to permitting is to state that the permit-holders (WDFW and PUDs) would produce the Protocols.

Hillman said the HCP-HCs and PRCC HSC will start in September and October to identify changes needed in the Protocols and by whom. Hillman said all topics should be discussed, then the Committees can decide which ones are topics that deserve further discussion and/or SOAs.

Larissa Rohrbach agreed to add review of the Protocols to the September agenda. Rohrbach also agreed to distribute the SOA on the Protocols drafting timeline[2] to the HCs and HSC to consider whether this SOA is acceptable to all committees. Committee members agreed to provide revisions to the Protocols drafting timeline SOA back to Tonseth for discussion during the June HCP-HC and PRCC HSC meeting.

C. Out-Planting Surplus Adult Methow Spring Chinook Salmon

Mike Tonseth said the 2017 *Out-Planting Surplus Methow Composite Spring Chinook Salmon Adults*[3] memorandum will be updated with details in the coming weeks but that returns are looking extremely low for 2019, so this may not be implemented this year.

---

[3] Chelan PUD, 2017. *Out-planting Surplus Methow Composite Spring Chinook Salmon Adults.* Prepared for the HCP Hatchery Committee. April 19, 2017.

D. NMFS Consultation Update

Brett Farman said the Methow Steelhead EA is out for public comment.[4] Farman said for the WNFH program EA, they are waiting for internal NMFS review before it can go out for comment, which is no change to the status from the last meeting.

Tracy Hillman asked how long the public comment period is. Farman said 30 days. Emi Kondo (NMFS) said the comment period closes May 2, 2019. Kondo said one general comment was received so far. Hillman and Catherine Willard asked what the comment was. Kondo said it's from a group that has submitted a generic paragraph about how hatchery fish are impacting other animals, but it is not well supported and will be noted for the record.

Farman said the Methow Steelhead EA and all summer Chinook salmon program HGMPs are out for public comment.[5] Once the comment period closes the decisions can be made and determination letters and permits finalized. Farman said Kondo has received requests to extend the permit review period—she has asked that everyone return comments as soon as possible. Kondo will attend the next meeting to discuss and resolve any comments.

Bill Gale said he has not seen language about the 4d determination. Kondo said she will follow up with Charlene Hurst to obtain the status of the 4d determination. Kondo said the 4d determination is less prescriptive so it may be that there would not be any additional terms and conditions added to those in the BiOp. Farman said Hurst is in the process of drafting the 4d determinations following the process for Evaluation and Recommend Determinations (ERD). Farman said he will also attend the May meeting.

Kirk Truscott said when he reviewed the unlisted Chinook salmon bundle, he found a typo—in the Douglas WDFW permit there was a reference to Grant PUD. Kondo said she will make note. Greg Mackey said Douglas PUD has flagged it and will send it in their responses to Kondo.

E. Streamlining HCP-HCs and PRCC HSC Meetings

Tracy Hillman reminded the committees that the protocols have been revised to streamline the HCP-HCs and PRCC HSC processes and materials.

Todd Pearsons asked if the conflict of interest SOA has been revised. Hillman noted that members discussed the idea of reducing and simplifying the SOA, but at this time the SOA has not been revised. Hillman noted it would be helpful to agree to the distribution method and lists.

---

[4] NOAA Fisheries public comment website: https://www.westcoast.fisheries.noaa.gov/hatcheries/UCRHatcheries_fall_summer-stlhd/UCR_smr-fall_hatch_rvw.html.

[5] NOAA Fisheries public comment website: https://www.westcoast.fisheries.noaa.gov/hatcheries/UCRHatcheries_fall_summer-stlhd/UCR_smr-fall_hatch_rvw.html.

Mike Tonseth supports the method of sending draft materials to primary representatives and alternates. Bill Gale agreed as long as USFWS can add a small set of specific people to the "primary" list. These people need to be on the primary list because they work on draft materials. Pearsons suggested developing a primary list that consists of representatives, alternates, and active participants, who receive all draft and final materials. Members suggested the primary distribution list include the addition of Betsy Bamberger, Shane Bickford, Deanne Pavlik-Kunkel, Pat Wyena (Wanapum Tribe), Charlie Snow, McClain Johnson, Michael Humling, and Cory Kamphaus. Hillman noted that the addition of Pavlik-Kunkel and Wyena would require approval by the HCP-CC.

Hillman said he will inform John Ferguson and Kristi Geris (facilitator and support staff for the HCP-CC, respectively) of the plan to develop a primary distribution list for distributing draft materials, and to add select participants to the primary distribution list, and a broader/secondary list for distributing only final versions of materials. Once the distribution lists are approved by the HCP-HCs and PRCC HSC, one the of representatives to the HCP-CC will advance the list to the HCP-CC for their approval.

Pearsons said Grant PUD has reservations about most of the issues discussed in the existing HCP-HC Conflict of Interest SOA that involve contracting, which should be discussed outside the PRCC HSC. Grant PUD is generally in favor of having a Conflict of Interest SOA, with revisions.

Larissa Rohrbach will re-distribute a revised Conflict of Interest SOA, meeting protocols, and updated distribution list for HC for approval in the May 2019 HCP-HCs and PRCC HSC meeting.

III. PRCC HSC

A. Approve the March 11 and March 20, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the draft March 11 conference call and March 20, 2019 meeting minutes as revised.

B. DECISION: Approve the 2019 Priest Rapids Hatchery M&E Implementation Plan

Todd Pearsons said no comments or revisions were received on the Draft 2019 Priest Rapids Hatchery M&E Implementation Plan. Tracy Hillman called for a vote to approve the Draft 2019 Priest Rapids Hatchery M&E Implementation Plan. All Parties of the PRCC HSC approved the Draft 2019 Priest Rapids Hatchery M&E Implementation Plan.

Grant PUD will finalize and Larissa Rohrbach will distribute the Draft 2019 Priest Rapids Hatchery M&E Implementation Plan to the PRCC HSC.

C. White River Memorandum Progress Update

Tracy Hillman said he asked for more direction from the PRCC on the development of the memorandum on the future of the White River Spring Chinook Salmon program. Hillman said Denny Rohr (PRCC facilitator) will have feedback for the PRCC HSC. Keely Murdoch said in the PRCC meeting, little progress was made in discussion because there was confusion about the status of the memo and program. Murdoch said some representatives thought there was agreement on developing a small technical group to issue a request for proposals. Murdoch said that Rohr requested more time to review past meeting summaries to understand the status of the memo and report back to the HSC. Bill Gale asked whether the plan is to discuss the topic further in the PRCC; Murdoch said yes but an agenda hasn't been issued for the next meeting. Murdoch said there was consensus agreement to extend the timeline to allow Craig Busack (NMFS) to participate.

Hillman noted this topic will remain ongoing.

IV. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are on May 15, 2019, at Grant PUD; June 19, 2019, at Grant PUD; and July 17, 2019 (TBD).

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: July 17, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the May 15, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, May 15, 2019, from 9:00 a.m. to 11:00 a.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Tracy Hillman will review aspects of the Independent Scientific Advisory Board's *Review of Spring Chinook Salmon in the Upper Columbia River* under HCP-HCs' purview (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is going)*
- Catherine Willard will update the genetics section of the *Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan)* based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*

- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will confirm with Andrew Murdoch that Wenatchee spring Chinook DNA sampling of the 2018 to 2023 returns is still consistent with the original Relative Reproductive Success Study extension agreement and provide an update to the extension. (Item I-A) *(Note: this item is ongoing.)*
- Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A). *(Note: this item is ongoing.)*
- Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding topics for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols. (Item I-A) *(Note: this item is ongoing.)*
  - Use of age-3 males in broodstock
  - Use of alternative, non-random mating strategies
  - Establishing ranges around broodstock collection targets
  - Collection sites for Chiwawa spring Chinook salmon broodstock
- Tracy Hillman and Larissa Rohrbach will add review of the Broodstock Collection Protocols to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item II-A). *(Note: this item is ongoing.)*
- Mike Tonseth will revise and redistribute the HCP-HCs Annual Broodstock Collection Protocols development timeline Statement of Agreement (SOA) (Item II-A). *(Note: this item is ongoing.)*
- Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service [USFWS]) and Charlie Snow (WDFW) to estimate the number of Methow spring Chinook salmon returns that are likely to return to Winthrop National Fish Hatchery to inform a translocation discussion in a future HCP-HCs meeting (Item II-B). *(Note: this item is ongoing.)*
- Mike Tonseth will revise and redistribute the 2017 *Out-planting Surplus Methow Composite Spring Chinook Salmon Adults* memorandum (Item II-B). *(Note: this item is ongoing.)*
- Emi Kondo (National Marine Fisheries Service [NMFS]) will confirm the status of the draft Wells Hatchery Methow Steelhead Program permit with Charlene Hurst (Item II-D).

Wells HCP Hatchery Committee

- Greg Mackey will provide a revised version of Douglas PUD's draft 2019 M&E Implementation Plan for HCP-HC approval by email (Item I-A). (*Note: This item is ongoing*)

PRCC Hatchery Subcommittee

- PRCC-HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item III-B). (*Note: This item is ongoing*)

Decision Summary

- The HCP-HCs and the PRCC HSC approved the updated meeting protocols and distribution lists in today's meeting (Item II-C).
- The HCP-HCs and the PRCC HSC will not re-activate the expired HCP-HCs Conflict of Interest Policy SOA (Item II-C).

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- The *Draft Grant County PUD Hatchery Monitoring and Evaluation Implementation Plan for Spring and Summer Chinook in the Wenatchee Basin and Summer Chinook in the Methow Basin 2020* was provided by Todd Pearsons on June 6, 2019 for a 30-day review period, as distributed by Larissa Rohrbach via email that same day. The review period ended on July 7, 2019.
- The *Monitoring and Evaluation of the Chelan and Grant County PUDs Hatchery Programs Draft 2018 Annual Report* and appendices was provided by Tracy Hillman on June 17, 2019 for a 30-day review period, and revised on June 20, 2019 as distributed by Larissa Rohrbach via emails the same days. The review period ends on July 17, 2019.

Finalized Documents

- The PRCC HSC-approved 2019 Priest Rapids Hatchery M&E Implementation Plan was finalized and distributed on May 20, 2019.
- The HCP-HCs and the PRCC HSC-approved Meeting Protocols and Distribution Lists were finalized and distributed on May 20, 2019.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the April 17, 2019 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and asked for any additions or changes to the agenda. No changes to the agenda were requested.

The HCP-HCs and PRCC HSC representatives reviewed the revised draft April 17 meeting minutes. Larissa Rohrbach said there were some minor revisions that the representatives then reviewed. The HCP-HCs and PRCC HSC representatives approved the draft April 17, 2019 meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on April 17, 2019, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on April 17, 2019)*:

Joint HCP-HCs and PRCC HSC

- *Tracy Hillman will review aspects of the Independent Scientific Advisory Board's Review of Spring Chinook Salmon in the Upper Columbia River under HCP-HCs' purview (Item I-A).*
  Hillman said this item is a long-term ongoing item.
- *Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A).*
  Tom Kahler said this item is ongoing. Mackey indicated in an email to Larissa Rohrbach that he may give a presentation on this topic during the June meeting.
- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A).*
  Tonseth said this item is ongoing.
- *Catherine Willard will update the genetics section of the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan) based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A).*
  Willard said she has made progress on this item and that it is ongoing.
- *Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A).*
  Truscott said he has made progress on this topic and a memorandum will be provided to the Committees within a week with potential approaches for elemental signature analysis for 2019. Truscott reminded the Committees the goal is to distinguish Okanogan spring Chinook

salmon from Methow spring Chinook salmon. In the memorandum, the CCT will propose an approach for analyzing scales, fin rays, and otoliths (otoliths require lethal sampling). He said some samples may be used for retrospective analysis to see how prevalent Methow fish may have been in the Okanogan brood in the past. He said the goal will be to minimize the number of Methow fish integrated into Okanogan brood in the future. He said spring Chinook salmon broodstock are already scale- and DNA-sampled but there is potentially a need to collect additional scales in 2019 for elemental signature analysis. He said water samples collected in the Okanogan and Methow rivers are also readily available for this type of assessment. He said these methods could be implemented in 2021 for the returning natural-origin adults so it's not too early to start testing whether these methods could be used to discern a difference between these populations.

- *Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A).*
  Farman said this item is ongoing.
- *Mike Tonseth will confirm with Andrew Murdoch that Wenatchee spring Chinook salmon DNA sampling of the 2018 to 2023 returns is still consistent with the original Relative Reproductive Success Study extension agreement and provide an update to the extension. (Item I-A)*
  Tonseth said this item is ongoing. He said the table in the memorandum is accurate, but he has identified language in the memorandum that is confusing. He said that he and Murdoch will revise the memorandum to clarify the agreement.
- *Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A).*
  Rohrbach said this item is ongoing. Several representatives noted they will be absent in June.
- *Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding topics for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols (Protocols) (Item I-A).*
  - *Use of age-3 males in broodstock*
  - *Use of alternative, non-random mating strategies*
  - *Establishing ranges around broodstock collection targets*
  - *Source for Chiwawa spring Chinook salmon broodstock*

  Hillman said this item is ongoing. Greg Mackey said in an email he may provide an update on alternative mating strategies during the June meeting. Catherine Willard reminded the Committees that these topics relate to 2020 brood collection, not 2019 brood collection.
- *Tracy Hillman and Larissa Rohrbach will add review of the Protocols to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item II-A).*

Hillman said this item is ongoing. The revisions to the development timeline SOA will be discussed in today's meeting.

- *Brett Farman will ask Amilee Wilson and Craig Busack (National Marine Fisheries Service [NMFS]) to clarify the intent of the direction provided in NMFS Biological Opinions (BiOps) for marking Chiwawa and Nason conservation programs juvenile spring Chinook salmon (Item II-A).*
  Farman said this item is complete.
- *Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service [USFWS]) and Charlie Snow (WDFW) to estimate the number of Methow spring Chinook returns that are likely to return to Winthrop National Fish Hatchery to inform a translocation discussion (Item II-C).*
  Tonseth said USFWS provided new information, which he is currently reviewing. Matt Cooper said Winthrop National Fish Hatchery has a lot of fish coming in as of this morning. Cooper said that Michael Humling ran the 3-population model looking at several out-planting scenarios and he sent the results to Tonseth for consideration. Cooper said the scenarios were designed to maintain high PNI on spawning grounds while still supplementing the number of fish on spawning grounds with hatchery-origin fish. For example, Humling modeled out-planting females only to avoid hatchery by hatchery spawning from occurring on the spawning grounds. Cooper said this is the likely proposal from USFWS.
- *Mike Tonseth will revise and redistribute the 2017 Out-planting Surplus Methow Composite Spring Chinook Salmon Adults memorandum (Item II-C).*
  Tonseth said this item is ongoing (see update to the previous action item).
- *Deanne Pavlik-Kunkel will provide Grant PUD's approval of routine distribution of merged PRCC HSC and HCP-HC meeting materials according to the revised meeting protocols (Item II-E).*
  Pavlik-Kunkel said this item is complete and will be discussed in today's meeting.
- *Once approved by the HCP-HCs and PRCC HSC, Tracy Hillman will present the revised merged HCP-HC and PRCC HSC distribution list to the HCP-CC for approval (Item II-E).*
  Hillman said during the last HCP-CC meeting, it was decided that it was acceptable for Hillman to propose the list to the CC rather than a representative. He said he will propose the list approved in today's meeting to the HCP-CC.

Wells HCP Hatchery Committee

- *Greg Mackey will provide a revised version of Douglas PUD's draft 2019 M&E Implementation Plan for HCP-HC approval by email (Item I-A).*
  Tom Kahler said this item is ongoing. Mike Tonseth said it is unlikely that spring Chinook salmon PIT tagging at the Priest Rapids Dam off-ladder adult fish trap will occur in 2019, because the Bonneville Power Administration has requested more time and background materials to review WDFW's proposal to shift from PIT tagging steelhead to PIT tagging

spring Chinook salmon. Tonseth said it is likely that WDFW will continue to PIT tag steelhead at the Priest Rapids Dam off-ladder adult fish trap in 2019.

PRCC Hatchery Subcommittee

- *Todd Pearsons will finalize the PRCC HSC-approved 2019 Priest Rapids Hatchery M&E Implementation Plan for distribution (Item III-B).*
  This item is complete. Larissa Rohrbach will distribute the final 2019 Priest Rapids Hatchery M&E Implementation Plan following the June meeting.
- *HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item III-C*).
  Hillman said he received feedback from Denny Rohr (Chair of the PRCC) and will discuss it during today's meeting.

II. Joint HCP-HCs and PRCC HSC

A. Broodstock Collection Protocols Development Timeline SOA Update

Tracy Hillman reminded the Committees that in the previous version of the Broodstock Collection Protocols (Protocols) development SOA,[1] the final draft is due for HCP-HCs approval 10 days prior to their February meeting (meeting occurs approximately February 15). Mike Tonseth said he will provide revisions to that SOA in June. Todd Pearsons said this should be based on the previously discussed approaches to addressing changes to the Protocols. Hillman reminded the Committees of their agreement to review the Protocols starting in September.

B. Out-Planting Surplus Adult Methow Spring Chinook Salmon Update

Mike Tonseth said the 2017 *Out-Planting Surplus Methow Composite Spring Chinook Salmon Adults*[2] memorandum will be updated based on progress described in the review of Action Items (Item I-A).

C. DECISION: Streamlining HCP-HCs and PRCC HSC Meetings

Distribution Lists

Tracy Hillman started the discussion by projecting and reviewing the proposed distribution lists that he and Larissa Rohrbach compiled. Hillman said there are two separate distribution lists: a primary list and a secondary (cc) list for each group (HCP-HCs and PRCC HSC) for a total of four distribution lists. He said it would be convenient if there were only two distribution lists (a primary list and a

---

[2] Chelan PUD, 2017. *Out-planting Surplus Methow Composite Spring Chinook Salmon Adults.* Prepared for the HCP Hatchery Committee. April 19, 2017.

secondary list), but consolidation of the four lists into two lists requires agreement from all parties. Hillman said alternatively, it would be nice to at least have one primary list and two secondary lists (one secondary list for the HCP-HC and one secondary for the PRCC HSC). Hillman said this will reduce the number of emails members receive.

Hillman started by reviewing the proposed primary lists to indicate which recipients are identified on one list but not on the other and asked members if they agree on the inclusion of recipients on a single primary distribution list. Hillman recorded decisions on the revised distribution list.

Hillman reviewed the proposed secondary lists and asked members if they prefer to maintain separate secondary lists. Tom Kahler said that because those on the secondary lists are receiving only final versions of documents, and final documents are publicly available on PUD websites, there should be little concern combining the secondary lists. Hillman reviewed each recipient and noted approval or revisions by the HCP-HCs and PRCC HSC.

Following review of individuals on the primary and secondary lists, Hillman asked the HCP-HCs and PRCC HSC if they approved the two lists. Members approved the two lists. Individuals on the primary list will receive all communications, while individuals on the secondary list will receive only final documents. Hillman will present the approved distribution lists to the HCP-CCs for their approval during their meeting on May 28 (the final updated distribution list is included in Attachment B).

Conflict of Interest SOA

Hillman said that the Conflict of Interest SOA has been revised and simplified considerably to be able to maintain an SOA but allow for more flexibility. Todd Pearsons said Grant PUD has some concern with what is being described as a conflict of interest. Pearsons said he can see the value of having an SOA, but the PRCC HSC doesn't make funding decisions, so the content needs to be represented correctly. Mike Tonseth said he had a similar concern with this content and suggested revisions to the language pertaining to the mission of the Committees members.

Keely Murdoch said she has some concerns about the need for recusing oneself from discussions. Murdoch said because the committees operate by consensus, a party that proposes a project could have a conflict of interest but would need to recuse themselves from discussion and voting on the project. However, this would not matter because the recused person would likely have given a positive vote and it would not change the outcome if all other members voted in favor of the project. Murdoch said a consensus-based committee minimizes the effect of conflicts of interest. Murdoch said that perhaps what is needed is an agreement to identify potential conflicts for the record in the notes. Hillman gave an example of when different entities respond to a request for proposals and respondents include voting members. Under this scenario, would there be a conflict of interest?

Murdoch and Catherine Willard said the Committees do not make funding decisions. Rather, the PUDs make those decisions.

Matt Cooper said Bill Gale (USFWS) wanted an SOA or a statement in the meeting protocols in case an outside party asks about the Committees' policy regarding conflicts of interest. Murdoch said these points could be summarized in the meeting protocols. Members agreed that there is no need for a conflict of interest SOA and noted that adding language to the meeting protocols stating that because decisions are consensus based in the Committees' and they do not make funding decisions, there is no need for members to recuse themselves from discussing and voting on decision items. Hillman said he would add language to the meeting protocols summarizing these points.

The HCP-HCs and PRCC HSC agreed to incorporate language on conflicts of interest into the meeting protocols document and not reactivate the lapsed conflict of interest SOA.

Meeting Protocols

Hillman said there are no new changes to the way the Committees operate; the revisions are intended to streamline the Protocols because all committees are now chaired or facilitated and supported by the same staff. Hillman projected and reviewed a draft version of the meeting protocols that included revisions from Grant PUD.

Cooper asked if the meeting protocols can be reviewed annually. Hillman said, yes, they can be reviewed annually or at any time. Kahler noted that the HCP Tributary Committees review their protocols annually and it would be appropriate for the HCP-HCs and PRCC-HSC to do the same.

Rohrbach and Hillman noted differences between HCP-HCs and PRCC HSC protocols, particularly that the HCP-HCs requires a 10-day notice of a decision item on an agenda. Rohrbach suggested meeting the requirement for a 10-day notice by including proposed agenda items and noting decision items in the call for agenda items that will be routinely sent 2 weeks in advance of the meetings.

Kirk Truscott noted that the HCP-HCs are more autonomous than the PRCC HSC. Truscott asked if decisions or SOAs made by the PRCC HSC require approval by the PRCC. Pearsons noted that not all SOAs become approved by the PRCC and that it is noted on the SOAs whether they are HSC-approved and/or PRCC approved. Murdoch asked what the difference is between declining to approve or abstaining from approval at the level of the PRCC. Pearsons said all SOAs go to the PRCC, but it is the PRCC's decision to weigh in whether to approve or not to vote at all. Tonseth suggested this level of detail may not be necessary for the meeting protocols.

Pearsons asked if it should be assumed that all SOAs go to the HCP-CCs and the PRCC HSC. Hillman said within the HCPs, it is possible that an SOA approved by the HCs (or the HCP Tributary

Committees) could be contested by the HCP-CCs and the CCs could then ask the HCs to reevaluate an agreement. Kahler noted that the attitude of the HCP-CCs has been deference to the HCs and Tributary Committees.

Hillman called for a vote on the revised version of the streamlined meeting protocols and all representatives of the HCP-HCs and PRCC HSC approved (the final updated meeting protocols are included in Attachment C).

D. NMFS Consultation Update

Emi Kondo provided an update on the Steelhead and Summer and Fall Chinook Salmon National Environmental Policy Act documents (Environmental Assessments). She said NMFS is still completing the Finding of No Significant Impact (FONSI) for the Steelhead and Summer and Fall Chinook Salmon Environmental Assessments. She said NMFS is crafting a FONSI document that states the action will not have a significant impact to the environment; therefore, an Environmental Impact Statement will not be necessary. She said that James Archibald (NMFS) is helping with the FONSI. She said there were no major comments on the Steelhead or Summer and Fall Chinook Salmon permits language. She said the major change is that permits will be extended to 2030. She said that after the FONSI is completed, the internal processes include two layers of internal review and West Coast regional review.

Kirk Truscott asked about the Wells Hatchery facility draft steelhead permit because the applicants haven't received a draft permit for review. Mike Tonseth said a BiOp is available but they have not received the draft permit from NMFS for review. Kondo said she will check with Charlene Hurst on the status of the Wells Hatchery program permit for Methow Steelhead.

Kondo also said there is an effort at NMFS to document and streamline the primary recipients for required reporting products and they could provide updates in future meetings. Brett Farman said another goal is to combine the reporting to meet permit conditions with bull trout encounter reporting for more accurate encounter tracking.

Todd Pearsons asked to whom at NMFS reports and protocols are submitted. Tonseth noted that different people at NMFS are recipients of different reports. Catherine Willard said it is her assumption that all materials are provided to the NMFS representative for appropriate distribution within NMFS. Tracy Hillman noted that all reports, plans, and materials are available in the HCP-HCs and PRCC HSC annual reports and those can be submitted to the NMFS representative on the Committees. He added it would be helpful if there is written guidance that all materials should be provided to the "NMFS representative" (rather than to a named individual), so that if there is turnover within the position, it will still be clear to whom those materials should be sent. Pearsons said it would be helpful to note in the permitting documents that it is the NMFS representative that is the single point of contact.

Kondo said NMFS will ultimately have an internal database-style list indicating which individuals are responsible for receiving which materials. She said it is NMFS's responsibility to ensure reports are received and reported in a timely manner. Farman said NMFS is making an effort to track this better.

Kondo then shared the two comments that were received on the upper Columbia steelhead and spring Chinook salmon hatchery programs and said they were noted for the record but did not contain substance that required action to be taken. Truscott asked how often it happens that no comments are submitted on hatchery permit environmental reviews, but those programs are later contested or litigated. Kondo said it is rare for comments to be submitted on hatchery permit environmental reviews and confirmed that no communication was received from entities who have contested hatchery programs in the past.

III. PRCC HSC

A. Approve the April 17, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the draft April 17, 2019 meeting minutes as revised (Item I-A).

B. White River Memorandum Progress Update

Tracy Hillman provided an update from Denny Rohr on the PRCC's response to the PRCC HSC's memorandum regarding the White River Hatchery Program. Hillman read from an email from Denny Rohr and said the PRCC direction is still under discussion within the PRCC. Hillman said the PRCC HSC will withhold from further discussion until further direction is provided from the PRCC HSC. Hillman said it would be ideal to receive direction soon to take advantage of Craig Busack's (NMFS) participation prior to his retirement. Keely Murdoch said this was an accurate summary of the status of the PRCC progress.

IV. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are on July 17, 2019, August 21, 2019, and September 18, 2019, at Grant PUD in Wenatchee, WA.

HCP Hatchery Committees and PRCC Hatchery Subcommittee Meeting Protocols

Last modified: May 15, 2019
HCP-HC and PRCC HSC Approval: May 15, 2019

Habitat Conservation Plans Hatchery Committees' Responsibilities

The Habitat Conservation Plans Hatchery Committees (HCP-HC) oversee development of recommendations for implementation of the hatchery elements of the three Habitat Conservation Plans (HCPs) for which Chelan and Douglas public utility districts (PUDs) have responsibility for funding. This includes overseeing the implementation of improvements, and monitoring and evaluation relevant to the PUDs' hatchery programs, as identified in the HCPs, the Permits, and Agreements.

Priest Rapids Coordinating Committee Hatchery Subcommittee Responsibilities

The Priest Rapids Coordinating Committee (PRCC) Hatchery Subcommittee (HSC) provides the primary forum for implementing and directing hatchery mitigation measures stipulated in the Priest Rapids Project Biological Opinion, May 3, 2004, outlined in Actions 26 to 31 of the Priest Rapids Project Salmon and Steelhead Settlement Agreement. The focus of the HSC is to resolve technical issues associated with the design, operation, and monitoring and evaluation of Grant PUD's hatchery mitigation program as identified in the Settlement Agreement. In fulfilling this purpose, HSC members will represent the policy directions of their organizations.

The HCP-HCs and PRCC HSC also coordinate in-season information sharing and discuss unresolved issues. HCP-HCs' and PRCC HSC's decisions shall be based upon the likelihood of biological success, time required to implement, and cost-effectiveness of solutions.

Members of the Wells, Rocky Reach, and Rock Island HCP-HCs and the PRCC HSC (collectively Members) represent a variety of federal, state, and tribal governments, and PUDs (collectively Parties).

Decision Making

1. The HCP-HCs and the PRCC HSC are decision-making bodies and make decisions or recommendations by consensus. Consensus is the unanimous consent of all respective committee members. Abstention does not prevent a unanimous vote.[3]
2. Decisions are made and recorded in two ways. The first is recorded in the meeting minutes and the second is recorded in a Statement of Agreement. In general, the most consequential decisions are recorded in Statements of Agreement.
3. If a Party or its designated alternative cannot be present for an agenda item to be voted upon, then the Party must notify the Chair/Facilitator, who shall delay a vote on the agenda item for up to five (5) business days. A Party may invoke this right only once per delayed agenda item.[1]
    a. The HCP-HCs and PRCC HSC have historically been amicable to a Party requesting additional time for internal vetting prior to a vote (within reason). This request and agreement typically have occurred during the meeting following contentious discussions and the inability to reconcile differences at that time.

[3] The identified protocol comes from the Anadromous Fish Agreement and HCPs for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects and the Priest Rapids Project Salmon and Steelhead Settlement Agreement for the PRCC HSC.

Attachment C
Final Updated HCP-HCs and PRCC HSC Meeting Protocols

Disputes and Conflicts

1. Dispute Resolution will follow the protocols and timelines defined in the HCPs and the Priest Rapids Salmon and Steelhead Settlement Agreement.
2. Conflict of Interest: Decisions and agreements made by the HCP-HCs and PRCC HSC require consensus, and funding and contracting issues are under the authority of the PUDs (not the HCP-HCs and PRCC HSC), therefore there is no need for a conflict of interest statement. There are no topics evaluated, discussed, or voted on by the HCP-HCs and PRCC HSC that would require recusing members due to conflicts of interest.

Meeting Protocols

1. The HCP-HCs and PRCC HSC shall meet monthly, or at least two (2) times per year, to conduct business and resolve disputes. In addition, any Committee Member can request to hold a special meeting of the Committees if at least one other Committee Member agrees to the meeting (requires two Committee Members). Every effort will be made to give Committee Members at least seven (7) days' notice of a special meeting. The Committee recognizes that sometimes unusual circumstances may result in fewer than seven (7) days' notice.
2. Agendas
    a. The Chair/Facilitator or Coordinator will distribute a draft list of agenda items and a request for additional agenda items fourteen (14) days before each meeting.
    b. Final agendas will be distributed seven (7) days before the next meeting.
3. Minutes
    a. Draft meeting minutes for review will be distributed within fourteen (14) days of the next meeting.
    b. Revised draft minutes for approval will be distributed within seven (7) days of the next meeting.
    c. Final meeting minutes will be distributed within three (3) days following approval.
4. Decision Items
    a. Decision items will be noted in the draft list of agenda items and draft decision documents (e.g., draft Statements of Agreement) will be distributed with the request for agenda items, or at least ten (10) days before a meeting at which the decision item is voted upon. This provision can be waived by agreement of all relevant Committee Members.
5. Action Item Summary
    a. Final action items, decision items, and agreements resulting from the meeting will be distributed within three (3) days of the completed meeting.
6. Final documents and other reports
    a. Documents approved as final, documents to support meeting discussion (e.g., journal articles), and other final reports (e.g., monthly hatchery reports) will be distributed with the final agenda or with final meeting minutes and action item summary unless otherwise indicated by Members.

Meeting logistics

Attachment C
Final Updated HCP-HCs and PRCC HSC Meeting Protocols

1. The meeting location will be the Grant PUD office in Wenatchee, Washington, unless agreed otherwise.
2. If a meeting is canceled, the regular schedule will remain unchanged.
3. Agenda items will be grouped by Committee (Wells, Rock Island/Rocky Reach, Priest Rapids or "Joint" if pertaining to the HCP-HC and PRCC HSC). Joint items will always be discussed first. Items relevant to the specific Committees will typically be presented in reverse order of the length of time required for discussion (i.e., Committees with agenda items requiring less time to discuss will go before Committees requiring more time for discussion). Agenda items will be listed under each Committee according to the order in which they were received. Revolving agenda items are covered last under each Committee.

Review of Plans and Reports

1. All Studies, Implementation Plans, and Reports prepared under the HCPs or Priest Rapids Project Salmon and Steelhead Settlement Agreement will be available for at least a 30-day review period unless decided otherwise.[1]
2. Plans shall be approved by a vote and reports will be finalized after review deadlines are exceeded and edits and comments addressed.

Document Distribution

1. SharePoint/Extranet Site and Email Distribution List Access
    a. The HCP-HCs agreed on a system requiring HCP Coordinating Committees review and approval to provide non-Members access to HCP Extranet Sites and email distribution lists. For example, if a Washington Department of Fish and Wildlife non-Member requests access to the HCP Hatchery Committees Extranet Site or email distribution list, the Washington Department of Fish and Wildlife HC Representative needs to pass the request to the Washington Department of Fish and Wildlife Coordinating Committee Representative, who then needs to request Coordinating Committee approval.
    b. Historically, administrative access (i.e., Chair or support) has been granted without Coordinating Committee approval; however, it is discussed with the Coordinating Committee at the next possible Coordinating Committee meeting.
    c. Materials relevant to the HCP-HCs will be saved to an Extranet site maintained by Douglas PUD. Materials relevant to the PRCC HSC will be saved to a SharePoint site maintained by Grant PUD.
2. Draft materials and requests for agenda items will be distributed to the Primary Distribution List that includes Representatives, Alternates, and a select group of recipients approved by Members. Final meeting materials and reports will be distributed to the Primary Distribution List and the Secondary Distribution List that includes a broader list of interested recipients.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: August 21, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the July 17, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, July 17, 2019, from 9:00 a.m. to 2:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Tracy Hillman will review aspects of the Independent Scientific Advisory Board's *Review of Spring Chinook Salmon in the Upper Columbia River* under HCP-HCs' purview (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing.)*
- Catherine Willard will update the genetics section of the *Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan)* based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*
- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*

- Mike Tonseth will revise the Relative Reproductive Success (RRS) Study extension agreement memorandum for clarity (Item I-A). *(Note: this item is ongoing.)*
- Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A). *(Note: this item is ongoing.)*
- Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding topics, as follows, for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols (Item I-A). *(Note: this item is ongoing.)*
  - Use of age-3 males in broodstock
  - Use of alternative mating strategies
  - Establishing ranges around broodstock collection targets
  - Source for Chiwawa spring Chinook salmon broodstock
- Tracy Hillman and Larissa Rohrbach will add review of the Broodstock Collection Protocols to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will revise and redistribute the HCP-HCs Annual Broodstock Collection Protocols development timeline Statement of Agreement (SOA; Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service [USFWS]) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to Winthrop National Fish Hatchery to inform a translocation discussion in a future HCP-HCs meeting (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will revise and redistribute the 2017 *Out-planting Surplus Methow Composite Spring Chinook Salmon Adults* memorandum (Item I-A). *(Note: this item is ongoing.)*
- Larissa Rohrbach will add HCP Policy Committee guidance on policy-level issues to the HCP-HC Meeting Protocols (Item I-B). (*Note: this language was added to the protocols under the section titled "Disputes and Conflicts." The updated version was saved to the HCP-HC Extranet Site and PRCC HSC SharePoint sites, dated July 17, 2019.)*
- Betsy Bamberger and Greg Mackey will distribute a draft 2020 study plan for *The Control of Saprolegnia Sp. Growth on Summer Chinook (Oncorhynchus tshawytscha) Eggs* (Item II-E).
- Greg Mackey will distribute a white paper reviewing broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item II-D). *(Note: this item is ongoing.)*

Wells HC

- Mike Tonseth will prepare a proposal for the Wells HCP-HC on the use of surplus summer Chinook collected from the Wells Volunteer Trap for the production of subyearling smolts to support the Southern Resident Killer Whale population (Item III-B).

PRCC Hatchery Subcommittee

- HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item V-B). (*Note: this item is ongoing.*)
- Keely Murdoch and Peter Graf will ask the PRCC whether members of the HSC can participate in the PRCC meeting when Jeff Jorgensen (National Marine Fisheries Service [NMFS]) discusses the Wenatchee life-cycle model and data needs (Item V-B).
- Tracy Hillman will compile questions from the PRCC HSC for Jeff Jorgensen during the August 21, 2019 meeting (Item V-B).

Decision Summary

- The Wells HCP-HC voted to approve the *Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs in 2019* in today's meeting (Item I-A).
- The PRCC HSC voted to approve the revised *Grant County PUD Hatchery Monitoring and Evaluation Implementation Plan for Spring and Summer Chinook in the Wenatchee Basin and Summer Chinook in the Methow Basin 2020* in today's meeting (Item V-C).

Agreements

- The Wells HCP-HC agreed to recommend to the Wells HCP-CC that Douglas PUD mark subyearling summer Chinook used for the Douglas PUD 2020 Survival Verification Study with coded wire tags (CWTs) with a unique code, in addition to passive integrated transponder (PIT) tags and adipose clips (Item III-A).

Review Items

- There are no items available for review.

Finalized Documents

- The Wells HCP-HC-approved plan for *Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs in 2019* was finalized in the meeting on July 17, 2019, and distributed via email by Larissa Rohrbach on July 22, 2019 (Item I-A).
- The PRCC HSC-approved *Grant County PUD Hatchery Monitoring and Evaluation Implementation Plan for Spring and Summer Chinook in the Wenatchee Basin and Summer Chinook in the Methow Basin 2020* was finalized in the meeting on July 17, 2019, and distributed via email by Larissa Rohrbach on July 22, 2019 (Item V-C).

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the May 15, 2019 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and asked for any additions or changes to the revised agenda. Hillman requested the addition of a Policy Committee Update to the agenda to follow the review of past minutes and action items. Catherine Willard requested a change to the Joint HCP-HCs and PRCC HSC topics to move an update on genetics monitoring to next month and to add a discussion on the film "Artifishal." The HCP-HCs and PRCC HSC approved revisions to the agenda.

The HCP-HCs and PRCC HSC representatives reviewed the revised draft May 15, 2019 meeting minutes. Larissa Rohrbach said there were some minor revisions that the representatives then reviewed. The HCP-HCs and PRCC HSC representatives approved the draft May 15, 2019 meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on May 15, 2019, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on May 15, 2019)*:

Joint HCP-HCs and PRCC HSC

- *Tracy Hillman will review aspects of the Independent Scientific Advisory Board's Review of Spring Chinook Salmon in the Upper Columbia River under HCP-HCs' purview (Item I-A).*
  Hillman said this item is ongoing.
- *Greg Mackey will continue researching broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A).*
  Mackey said he will provide an update in today's meeting. This item is ongoing.
- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A).*
  Tonseth said this item is ongoing.
- *Catherine Willard will update the genetics section of the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan) based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A).*
  Willard said this item is ongoing.
- *Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from*

other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A).
Truscott said this item is ongoing.

- *Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A).*
  Farman said this item is ongoing. Tracy Hillman said that Ford et al.'s[1] (NMFS) iterative approach for estimating PNI was used in the *Monitoring and Evaluation of the Chelan and Grant County PUDs Hatchery Programs Draft 2018 Annual Report* (Chelan and Grant PUD's M&E Report) rather than the simple approach that is identified in the permits. Catherine Willard and Hillman asked if NMFS would concur that use of this approach is suitable. Farman said, yes, he concurs that the approach taken in the Chelan and Grant PUDs M&E report is suitable.
- *Mike Tonseth will confirm with Andrew Murdoch (WDFW) that Wenatchee spring Chinook DNA sampling of the 2018 to 2023 returns is still consistent with the original Relative Reproductive Success (RRS) Study extension agreement and provide an update to the extension (Item I-A).*
  The RRS study extension agreement memo was revised by Mike Tonseth and distributed to the HCP-HCs and PRCC HSC via email by Rohrbach on July 16, 2017. Bill Gale noted that the memo requests that the Rock Island HCP-HC approve the updated memo. This will be added as a decision item will be added to the August agenda. This item is ongoing.
- *Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A).*
  Rohrbach said this item is ongoing.
- *Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding topics for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols (Protocols) (Item I-A).*
  - *Use of age-3 males in broodstock*
  - *Use of alternative, non-random mating strategies*
  - *Establishing ranges around broodstock collection targets*
  - *Source for Chiwawa spring Chinook salmon broodstock*

  Hillman said this item is ongoing. Greg Mackey will discuss the use of alternative mating strategies in today's meeting.
- *Tracy Hillman and Larissa Rohrbach will add review of the Broodstock Collection Protocols to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item II-A).*
  Hillman said this item is ongoing.

---
[1] Ford, M. 2002. Selection in captivity during supportive breeding may reduce fitness in the wild. Conservation Biology 16:815-825.

- *Mike Tonseth will revise and redistribute the HCP-HCs Annual Broodstock Collection Protocols development timeline SOA (Item II-A).*
  Tonseth said this item is ongoing.
- *Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to Winthrop National Fish Hatchery to inform a translocation discussion in a future HCP-HCs meeting (Item II-B).*
  Tonseth said this item is ongoing.
- *Mike Tonseth will revise and redistribute the 2017 Out-planting Surplus Methow Composite Spring Chinook Salmon Adults memorandum (Item II-B).*
  Tonseth said this item is ongoing.
- *Tracy Hillman and Larissa Rohrbach will distribute HCP-HC and PRCC HSC-approved distribution lists and meeting protocols (Item II-C).*
  Rohrbach distributed the updated meeting protocols and distribution lists by email on May 20, 2019. This item is complete.
- *Tracy Hillman will present the HCP-HC and PRCC HSC-approved distribution lists to the HCP-CC for their approval (Item II-C).*
  The HCP-CC approved the updated HCP-HC meeting protocols and distribution lists on May 21, 2019. This item is complete.
- *Emi Kondo will confirm the status of the draft Wells Hatchery Methow Steelhead Program permit with Charlene Hurst (Item II-D).*
  Brett Farman said he will provide an update in today's meeting. This item is complete.

Wells HCP Hatchery Committee

- *Greg Mackey will provide a revised version of the Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs in 2019 (Douglas PUD's 2019 M&E Plan) for HCP-HC approval by email (Item I-A).*
  Mackey said Douglas PUD would like to finalize a version of the plan that excludes edits regarding potential changes to methods for estimating steelhead spawner abundance and distribution [that currently rely on detections of upstream-migrating steelhead that are PIT tagged at the Priest Rapids Dam Off-ladder Adult Fish Trap (OLAFT)]. Mike Tonseth said steelhead sampling at the OLAFT is still taking place this year. Keely Murdoch said the edits were written to alert the committee that changes to the run-size modeling approach should be retained so they can be revisited in Douglas PUD M&E Plan for 2020 (next year's plan). Mackey said the language in the plan should be more specific and said the edits provided were too vague. Edits were made during the meeting to specify the run-size modeling methods for brood year 2020 fish (to be carried out in 2019). Tracy Hillman called for the Wells HCP-HC to vote to approve Douglas PUD's 2019 M&E Plan and all parties approved.

PRCC Hatchery Subcommittee

- *HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item V-B).* Hillman said there has been no feedback and this item is ongoing.

B. Policy Committee Update

Tracy Hillman provided a summary of HCP Policy Committees guidance directed toward the HCP Hatchery Committees regarding the process and criteria for elevating topics from the HCs to the Policy Committees. Hillman summarized a situation regarding a dispute in the HCP Tributary Committees where a project was deemed biologically relevant, but a policy-level consideration overrode the selection criteria at the technical level. Hillman said a formal dispute was pulled back because the parties acknowledged they would not come to resolution by following the HCP dispute resolution process. The Yakama Nation (YN) asked to convene the HCP Policy Committees to determine a path forward.

Hillman said the HCP Policy Committees provided guidance to all technical groups, including the HCP Hatchery Committees and HCP Coordinating Committees. Hillman said that HCP Hatchery Committees will base decisions on the technical merits of the issue. Any policy-level concerns impeding decision making will be elevated to the HCP Policy Committees for review and a decision.

Bill Gale asked if these recommendations from the HCP Policy Committees will be documented somewhere. Hillman said they will be recorded in the Policy Committees meeting minutes. Gale asked if this guidance changes the dispute resolution direction given in the HCPs. Hillman said no, this guidance does not pertain to official disputes. Gale said this could result in HCP Hatchery Committees members asking for an issue to bypass the Coordinating Committees and go directly to the Policy Committees. Hillman said if it's disagreement or dispute regarding a technical issue, it should still go to the HCP Coordinating Committees. Kirk Truscott said this guidance was developed by the Policy Committees because if it's a policy issue, meaning if it's a top-down issue with direction from existing policy, it is a waste of time to take the issue through the HCP dispute resolution process. Truscott gave the example when recalculation of the Chiwawa program size was not agreed to on a policy level due to *US v. Oregon*, the issue was resolved at the policy level first in order for changes to go forward on the technical level. Gale asked if the HCP Hatchery Committees are solely technical committees and if policy should not be discussed. Hillman said the guidance from the Policy Committees is to evaluate issues based on technical merits. Gale said he wants to ensure the guidance provided by the HCP Policy Committees is aligned with the HCPs. Hillman said the Policy

Committees do not want to change the HCPs. Tom Kahler said the intent of the HCP Policy Committees decision was not to change the operation of the technical committees, but was intended to provide a means to resolve policy conflict resolution outside of the technical committees.

Gale asked how the HCP Tributary Committees issue was resolved. Hillman said the issue is to be resolved by asking leadership of the member parties in conflict to meet and come to resolution with the biological merits in mind. Hillman said the Policy Committees intend to educate tribal council members on the purpose and objectives of the HCPs. Gale said the solution to any issue that may rise to the HCP Policy Committees could be rooted in both groups (technical and policy) by providing a technical workaround. Keely Murdoch agreed but said that providing a technical workaround, in this case, did not get to the core policy issue that had no nexus to the resource and was going to continue to be a problem if the Policy Committees were not engaged.

Murdoch suggested memorializing this development in a place that is more accessible for new committee members and future uses. She said it should be incorporated into the operating protocols. Larissa Rohrbach will add the HCP Policy Committee guidance to the HCP-HC and PRCC HSC protocols files (*Note: this language was added to the protocols under the section titled "Disputes and Conflicts." The updated version was saved to the HCP-HC Extranet Site and PRCC HSC SharePoint sites, dated July 17, 2019.)*

II. Joint HCP-HCs and PRCC HSC

A. Goat Wall Acclimation Site Performance Update

Tracy Hillman welcomed Rick Alford (YN) who gave the presentation, "*Goat Wall Acclimation Site, Methow Valley*" (Attachment B). Alford shared a PowerPoint presentation on operations and outcomes of acclimation activities for spring Chinook salmon at the Methow Valley Goat Wall site in the upper Methow River from 2017–2019.

Slides 1–8: Alford presented background information about the Goat Wall Acclimation Site. It is located 25 miles up the Methow River on Cold Creek, a disconnected side channel of the Methow River. Todd Pearsons asked if it is Methow River water; Alford said yes. Water temperatures range from the 30s°F to 40s°F, depths 1 to 1.5 meters, and capacity is about 30,000 fish with a conservative stocking density. The habitat is more complex in the downstream area than upstream area of the side channel. Snow and access can be challenging.

Slides 9–16: Alford described the activities to set up the acclimation site in spring. Snorkel surveys are conducted to identify other fish. Pearsons asked if it is completely enclosed; Alford said yes, the sites have custom nets. Best efforts are made to secure the nets so no fish escape. Fish transport trucks bring juveniles. Methow Fish Hatchery staff support the collection of the fish from the hatchery. Snorkel surveys are done to monitor fish and three PIT-tag detection systems are used to monitor for escapees. During rearing, staff visit up to five times a day to feed and haze predators. Growth monitoring and fish health samples are taken. All activities are done by boat. Feed is kept off site and the site is maintained in a clean condition to meet the landowners' needs. The landowners have been very supportive. Pearsons asked if the side channel has been blocked off. Alford said they have to maintain connectivity of the side channel to the Methow River.

Slides 17–18: Alford summarized the outcomes of three years of activities (2017–2019). The beginning of acclimation depends on flow and ability to access the site through snow. Releases are timed to coincide with Methow Fish Hatchery releases to compare survival between these two groups. Pearsons asked if fish are ushered out of the side channel at the time of release. Alford said release is completely volitional. Fish may move upstream or downstream once the nets are dropped. PIT-tag arrays are monitored for 2 to 3 days following release to ensure all fish have moved out. Net security was good with 1.2% fish escaping pre-release.

Slides 19–21: Alford summarized in-river survival and travel time results. Survival is calculated using PIT tags and the Cormack-Jolly-Seber mark-recapture model. Survival of Goat Wall-acclimated fish to Rocky Reach Dam is similar to Methow Fish Hatchery releases. This year, survival to McNary Dam may not be as good as other programs due to low flow conditions [in the Methow River].

Slide 22: Alford showed adult return data for the first returning cohort from brood year 2015 based on PIT tags detected at Wells Dam this spring. He said 2019 is the first year of 4-year-old fish returning from this acclimation site to the Methow Basin. Estimated smolt-to-adult return rates to Wells Dam were presented in comparison to other production groups.

Hillman asked if the acclimation site is spring-fed. Alford said the geology in the area is interesting. The side channel is fed by a type of underground river. When the water level in the Methow River goes down, water level in this site goes down and vice versa.

Bill Gale asked if the YN is monitoring site-fidelity to observe whether the project encourages more upstream distribution of spawners. Alford said yes, that adult distribution monitoring will start this year. Alford said PIT tags will not be monitored upstream of Winthrop. Keely Murdoch said data will be collected from CWTs collected in spawner surveys. Murdoch added there will be a small run this year and data may be limited. Gale said it may be difficult to observe a shift in distribution due to small samples sizes. Gale added the combination of small releases, low return rates, and low observation rates in the carcass sampling may make it difficult to have confidence in a potential shift in distribution.

Pearsons asked if there is a model to estimate predation effects on survival during acclimation. Alford said yes, they use a model based on literature and predators observed on site. Pearsons said the survival rates presented are unusually high for a natural site. Alford said yes, they haven't seen many predators on site.

Catherine Willard asked how long it takes for fish to leave the site volitionally. Alford said spring Chinook leave quickly, in approximately 5 days. Alford added the fish overwhelm the PIT-tag readers and PIT-tag detection efficiency can be low during the release period [due to tag collisions].

Pearsons asked about the duration of the study. Murdoch said it is a 5-year study; however, the HCP-HCs will need to evaluate the preliminary outcomes of the study prior to the complete adult return record to decide on the future of the site. Murdoch said the HCs should discuss whether they should move forward with evaluating site performance with a partial return dataset or wait for a more complete set. Gale said the understanding site fidelity of returning adults is important, but work can proceed without the complete dataset of returns as long as juvenile survival estimates are available to evaluate.

B. 2018 Egg Treatment Study Update

Betsy Bamberger presented the results of the study (Attachment C) and said the 2018 Egg Treatment study plan was originally brought to the HCP-HCs in July 2018 as a proposed pilot study to test various treatment methods for preventing infestation with the water mold *Saprolegnia spp.* with the goal of reducing formalin use [by Douglas PUD programs to preemptively address potential future regulation and health and safety issues].

Bamberger said the treatments tested were formalin, salt, hydrogen peroxide, and no treatment (water). She said no difference was observed between the treatments, indicating that all treatment methods were equally effective. She hypothesized that the pathogen load was too low in the water source [at Methow Fish Hatchery] to observe a difference if one exists. She said follow-up work is needed to determine the best egg treatment protocol at Methow Fish Hatchery.

Bamberger said some differences between the pilot study and real world uses are that summer Chinook salmon were used in the study instead of the target species, spring Chinook salmon, due to limitations on spring Chinook salmon availability and permitting issues. Bamberger said another difference was that incubation trays were used that are different from the incubation isobuckets used for rearing spring Chinook salmon embryos.

Greg Mackey said the experiment was run until embryos reached the eyed-egg stage, per study design. Further, the HCP-HCs later approved observing a subset of the fish to the alevin stage to examine if treatment effects carried past hatch. However, no additional effects were observed at the alevin stage. Bamberger said salt had an effect on the alevin stage in other published studies.

Bamberger said staff reported that non-treated eggs were stickier than formalin treated eggs.

Mike Tonseth asked if the treated eggs were subjected to the same shocking and handling as eggs in the spring Chinook salmon production program. Bamberger said yes, in fact they were probably handled more because eggs from different females were mixed to reduce familial effects on egg survival.

Bill Gale asked if the intent is to repeat the study in a place where there is a higher *Saprolegnia* load. Bamberger said yes, they intend to repeat the study at Wells Fish Hatchery with summer Chinook salmon this fall (2019). Tonseth said that implementing the study in a hatchery with a low *Saprolegnia* load was an original critique of the study, but due to facility modifications, Wells Hatchery wasn't prepared to house the study in 2018. Mackey said implementation of this first year was an opportunity to develop the methods.

Gale asked if the problem with hydrogen peroxide is that it's difficult to procure. Bamberger said yes, the Department of Homeland Security has to be informed, but it's easier if there is a plan to use it on a short timeline and it is easier to acquire in smaller volumes.

C. 2019 Egg Treatment Study Plan

Betsy Bamberger said the Egg Treatment Study will be repeated in 2019 using summer Chinook salmon with the addition of another treatment group. Greg Mackey said they plan to eliminate the use of hydrogen peroxide because it is difficult to handle.

Mike Tonseth asked if the plan is to use the existing broodstock or to collect additional broodstock for the study. Mackey said if a treatment doesn't work, an egg stack could be lost to *Saprolegnia*, but if the risk is low, existing program production fish could be used. Mackey said formalin is already used on the production fish so for formalin, production fish would be used as per the usual treatment at the hatchery. He added that at this time the study will be kept small to make it easier to collect enough eggs.

Bamberger and Mackey will provide another draft study plan in August for review and approval by the Wells HCP-HC.

Tracy Hillman asked if there will be replication at other sites. Bamberger said no, not at this time. Tonseth said implementation of these types of studies will depend on the relative risk to each program.

D. Alternative Broodstock Composition and Mating Strategies

Greg Mackey summarized how this topic was originally raised. Mackey said the original question was whether to use jacks in the broodstock, focusing on spring Chinook in the Methow basin. He said the policy so far has been to exclude jacks in the broodstock, but that in the recent Broodstock Protocol allowance was made to use wild jacks if wild male broodstock were in short supply. Mackey said in researching this topic he determined that the question is actually about constructing the mating strategies overall, of which jacks are one component.

Mackey said the following pertains mostly to the conservation programs. Mackey said there are two major themes for maintaining a conservation broodstock:

1. A "genetically benign" approach that attempts to collect random sample to match the genetic composition of the broodstock with the wild stock. Mating is random to the extent possible. The male to female ratio could be 1:1 or a spawning matrix can be used. There are efforts made to minimize domestication selection. There are guidelines to cull (equalize) families to maximize effective population size. The goal is to have no effect on the natural population with what is done with the hatchery population.

   Mackey noted two relevant publications. He said Don Campton (USFWS) wrote a paper[2] about sperm competition, though much of the paper discusses the genetically benign approach in broader terms. Tom Quinn wrote a response paper[3] comparing what hatcheries actually do compared to what fish do in the wild.

2. Dave Hankin's paper[4] focuses on counteracting the directional selection for younger age at maturity in hatchery populations, especially if there is a fishery that tends to select the older, larger fish. Hankin modelled an approach using non-random mating. Hankin prescribed an approach where jacks are not used. Instead, for each female, a male that is equal size or greater is used to fertilize eggs, which [practically] guarantees that the male and the female are the same age or the male is older. This practice would drive the population toward older age at maturity, countering the effects of hatchery production and fisheries.

Mackey said the Methow Fish Hatchery uses a spawning matrix for spring Chinook. Mackey said the Busack and Knudsen paper[5] does a great job describing matrix-based spawning methods. The

[5] Busack, C., and C.M. Knudsen, 2007. "Using factorial mating designs to increase the effective number of breeders in fish hatcheries." *Aquaculture* 273:24–32.

question remains whether jacks should be used. Warm Springs National Fish Hatchery is using an approach where they use jacks in proportion to their natural occurrence in the wild, but decrease their use in the hatchery in proportion to their relative reproductive success as compared to large males in the wild. One way to approach this would be to estimate their contribution [to the offspring] as done in the Berejikian paper[6] and multiply the average contribution of jacks by their occurrence [in the total population?].

The Committees discussed the current genetic health of the Methow Spring Chinook population. Mackey said there are often spinal deformities in hatcheries. Deformities have been observed over the years at Wells Hatchery for summer Chinook, but the reporting has been spotty. Betsy Bamberger looked into the causes of spinal deformities and there are different types and the causes are not well-understood. Mackey talked to Ron Hardy (University of Idaho; animal nutrition expert), who says it's always a nutrition issue (a phosphorous limitation). Douglas PUD contracted with the WDFW Molecular Genetics Laboratory to genotype a sample of 50 of the deformed fish at Methow Hatchery for the 2018 brood to determine whether it could be a genetic problem. Mackey said Sewel Young et al. (WDFW 2019)[7] used the results of this analysis to compare the homozygosity of hatchery-origin Twisp River spring Chinook salmon with all of the Snake River basin spring Chinook salmon populations. He found that the Twisp River hatchery-origin fish had lower homozygosity than the entire Snake River population. By this preliminary measure it would appear that the Twisp River component of the Methow Hatchery program has done a good job for maintaining genetic integrity.

Mackey said the Methow River basin hatchery program appears to be doing a good job but there could be other, better ways for doing things. Bill Gale said there may be some programs that follow Hankin's concept and it should be contemplated but programs should avoid being overly selective for a few spawners that meet the criteria. Gale said there is value in maintaining the criteria for random mating. Mackey said Jennifer McLean (University of British Columbia) studied the effectiveness of program random mating and found that unconscious bias results in mating that actually isn't very random.[8]

Mackey said he will provide a white paper to the HCP-HCs and PRCC HSC and a presentation during the August meeting to summarize his conclusions. *(Note: Mackey's white paper will be distributed following PUD review.)*

E. Out-planting Spring Chinook Salmon Adults in Chewuch 2019 Status Update

Greg Mackey said this year the Methow spring Chinook salmon run was predicted to be quite small. Mackey said out-planting depends upon whether there are extra fish available and whether adult management should be done this year following the protocols for surplusing fish. Mackey said the Methow Fish Hatchery has collected all their broodstock for this year. Bill Gale said broodstock is available at Winthrop but is not meeting the Methow Hatchery-origin adult target for the Winthrop program. Mackey said fish continue to trickle in at Methow Hatchery. Keely Murdoch asked if USFWS knows how many more fish are needed to meet natural-origin fish targets. Matt Cooper said they have less than half of the target of Methow Hatchery-origin brood pairs but have plenty of WNFH-origin returns to backfill the program.

Rick Alford asked where the out-planting sites on the Chewuch River are located. Mackey said they were based on preliminary surveys to identify sites that were not already occupied by wild fish and allowed access for planting trucks. Tom Kahler said release sites were identified at river kilometer (RKM) 29 and RKM 14 on the Chewuch River.

Tracy Hillman summarized that it is unlikely that the out-planting of spring Chinook salmon will occur this year.

The HCP-HCs will continue to move forward with updating the Methow spring Chinook salmon translocation plan. Murdoch said this was originally intended as an alternative to acclimation. Murdoch said the intent was to compare the results of out-planting with acclimation. Mike Tonseth said if there are not sufficient conservation program fish, it may be worth experimenting with Winthrop National Fish Hatchery HOR program fish to study behavior and success, though it would affect PNI on the spawning ground.

Gale asked how much of the Methow Spring Chinook Salmon Conservation program fish are remote acclimated. Mackey said of the approximately 224,000 juveniles, more than half are acclimated remotely. Gale said, so only half of the program is being acclimated at the Methow Fish Hatchery because they are being remotely acclimated. Murdoch said Twisp acclimation sites are not necessarily remote acclimation.

Gale asked if the Methow program is trying to do too much with a small number of adults returning to Methow Fish Hatchery. Gale said even in an average return year there may not be enough fish for translocation. Gale suggested reviewing smolt-to-adult return rates (SARs) to determine what would actually be needed to implement the translocation plan. Tonseth said the determination may not be on total Methow spring Chinook SARs, but rather a comparison of the number of adults returning to the out-plant sites versus the hatchery.

F. Artifishal

Catherine Willard said that the Cascade Columbia Fisheries Enhancement Group (CCFEG) is showing the movie "Artifishal" at the Snowy Owl Theater in Leavenworth on August 8. CCFEG asked if local entities would be willing to participate on a panel discussion after the movie.

Willard said the movie is quite biased. Bill Gale said USFWS asked for the ability to watch the movie and determine who would be on the panel first. Gale said USFWS has not responded yet but is willing to consider participating. Keely Murdoch said YN would require approval from their media committee and the Tribal Council to participate. Murdoch said YN is discussing it and have told CCFEG that a person will likely participate but has not determined who that will be. Murdoch said they will likely review the movie first and determine their approach to answering questions. Gale said a screening in the Methow community went well (in Winthrop, WA). Tom Kahler said he questioned whether the panel will happen with or without their participation. Gale said he is concerned about the screening of the film without a panel to provide context.

Tracy Hillman asked if the CCT will participate. Kirk Truscott said they would have to ask approval of their media council. Truscott said the CCT response was that it was a bad idea to give any time to the film because it appears to be propaganda. Gale said it is unfair to be asked to be on a panel without being able to view the material for discussion. Todd Pearsons said Grant PUD has no plan whether or not to participate at this time. Brett Farman said NMFS had an internal screening but no formal response that he is aware of. Willard said Chelan PUD prefers that CCFEG do not show the movie because it is biased and does not accurately reflect the hatchery programs in the upper Columbia, but feels they need to participate to provide a balanced view. However, Chelan PUD feels there will not be enough time during the panel discussion to describe how these programs are different from what is being shown in the movie. Gale said they conflate net-pen rearing of Atlantic salmon with hatchery rearing across the entire landscape. Gale asked if anyone knows CCFEG's motivation for bringing this movie to the valley. Chelan PUD read from an email that CCGEG feels this provides an opportunity to have a balanced discussion. Mike Tonseth said screening the film and panel time are not an adequate way to provide a balanced discussion. Greg Mackey said asking to stifle the film is worse that participating in a biased discussion.

Willard asked if the participants should prepare a letter asking for better explanation of the intent of showing the film and an opinion on a joint response for preparing a more balanced discussion. Peter Graf suggested asking for some speaking time to introduce how the HCP programs are different from what is shown in the film. Willard agreed it would be helpful to be able to explain the programs before taking questions. Hillman asked if the HCP-HCs and PRCC HSC would like support to facilitate participation of members. Potential participants will coordinate outside of the committees.

G. Wenatchee Spring Chinook Salmon Broodstock Collection Update

Mike Tonseth gave an update on the number of adults that have been retained for Wenatchee spring Chinook salmon broodstock. Tonseth said there are currently:

- Nason Creek spring Chinook salmon: 52 NOR, 77 HOR (129 total)
- Chiwawa River spring Chinook salmon: 37 NOR, 40 HOR (77 total)

The program is 25 fish below target numbers for Chiwawa NOR. Collection of NOR is continuing at Tumwater Dam and any that assign genetically to the Chiwawa population with 95% surety will be retained. Ten fish collected at Tumwater Dam are awaiting assignments. The numbers arriving at Tumwater Dam are declining rapidly for the season.

Tonseth said this year the number of fish captured at Tumwater Dam that did not assign to Nason nor Chiwawa populations was almost double the number sent back to the river compared to previous years due to non-assignment to either population. Tonseth said there were 14 non-Nason/non-Chiwawa-assigning fish and an unusually high number of those assigned genetically back to Leavenworth National Fish Hatchery. Bill Gale said there could have been a problem with the cutoff for the genetic stock identification criteria. Peter Graf asked for clarification whether fish that do not assign with at least 95% surety to either program would be allocated to the safety net program. Tonseth said no, they would be released back to the river.

Tracy Hillman summarized that both Nason and Chiwawa programs have met the overall brood goals, but the NOR target has not been met for the Chiwawa program.

H. National Marine Fisheries Service Consultation Update

Brett Farman said that the Steelhead and Summer and Fall Chinook Salmon Environmental Assessments Finding of No Significant Impact (FONSI) is still in internal review. Farman said the Winthrop Steelhead permit is waiting for a signature. Farman said the permit for the Methow Steelhead program was sent out by Charlene Hurst at the end of May, comments were received by mid-June, and it is awaiting signature when the FONSI is finalized. Farman said there are no hard dates for completion once permits go into internal review.

III. Wells HC

A. Wells Hatchery Summer Chinook Salmon Tagging for the 2020 Survival Study

Tom Kahler said that every 10 years Douglas PUD implements a survival verification study (survival study). The next study will be conducted in 2020 using Wells Hatchery summer Chinook salmon. In May 2009, the Wells HCP-HC decided not to tag the 2010 survival study fish with CWTs because they would already be PIT tagged for the survival study. The primary difference between then and now was that in 2010, the entire study fish group was in addition to the hatchery production numbers. In 2020, the study fish (110,000 fish) would be taken from the total yearling summer Chinook hatchery production of 320,000 fish. The study fish would receive PIT tags and would be adipose fin-clipped (ad-clip). The remaining 210,000 production fish would receive CWTs and would be ad-clipped. The HCP Coordinating Committee asked whether there would be any adverse effect on the monitoring and evaluation activities and *US v. Oregon* agreements due to not tagging 110,000 fish with CWTs. The HCP Coordinating Committee was interested in getting input from the HCP-HC on this issue.

Kahler said CWTs are used by Douglas PUD for determining age structure, harvest, and stray-rates. An assumed mark-retention rate is applied to the numbers. One challenge would be calculating a different mark-retention rate for 2020 because there would be a different mark rate.

Mike Tonseth said ocean harvest cannot be calculated without CWTs. Tonseth said the concern is whether PIT tags would suffice as a surrogate for CWTs. The upper Columbia is the only place where PIT tags are interrogated in the recreational fishery.

Kirk Truscott said the Wells Hatchery stock is the indicator stock for harvest on upper Columbia summer Chinook salmon, including in the Alaskan and Canadian fisheries. In approximately 2005, the HCP-HCs determined that 100% tagging is needed to provide sufficient rigor to estimate ocean harvest.

Bill Gale said fish frequently dip into numerous different tributaries. The problem with PIT tags is that you don't know if they stay. Gale asked why Douglas PUD is using production fish for the survival study and not additional fish as in 2010. Kahler said the Coordinating Committee decided this in February 2019.

Tonseth said the consultation with NMFS is moving forward without the additional fish. He said that in the *US v Oregon* tables, the survival study fish were removed.

Kahler said that of the 110,000 survival study fish, 50% will be released downstream from Wells Dam from a barge (the release methodology used in the survival studies to ensure similar fish handling and release protocols for all release groups, above and below the dam), 25% will be released at the mouth of the Methow River, and 25% will be released at the mouth of the Okanogan River (approximately 50,000 fish released upstream from Wells Dam).

It was asked if the HCP-HC is subordinate to the HCP-Coordinating Committee. Truscott said in the case of planning the survival studies they are.

Tonseth said that not tagging production fish with CWTs would deviate from *US v. Oregon*. This would require a revision to the *US v. Oregon* tables, then revising them back in the future. Gale said that *US v. Oregon* also stipulates fish be released on station.

Keely Murdoch said there is a need to CWT 100% of the fish to achieve adequate sample sizes to determine ocean harvest rates. Gale said there are two problems. One is the deviation from *US v. Oregon*, and the second is the deviation from the preferred tagging method determined by the HCP-HC.

Kahler said a decision on double-tagging has not been made; it is up to the HCP-HC to provide that determination.

Tonseth said it would be prudent for the survival study fish to have a unique CWT code. Tonseth said in looking ahead to 2030 to track spring Chinook salmon survival, PIT tagging production fish may be necessary, but they should have similar performance as non-PIT tagged fish. A unique CWT number would allow for estimating differential survival of PIT-tagged fish.

Kahler asked whether the Comparative Survival Study found differential survival of PIT-tagged fish (reported in the 2018 annual report). Kahler said the HCP Coordinating Committee did agree that spring Chinook salmon should be the study fish in 2030.

AGREEMENT: The direction from the HCP Hatchery Committee to the HCP Coordinating Committee is to tag all 2020 survival study fish with CWTs that have a unique group code in addition to tagging with PIT tags and ad-clipping.

Kahler will report the agreement back to the HCP Coordinating Committee.

Peter Graf asked if using a unique CWT code for a smaller number of fish still meets the need of an adequate sample size for estimating harvest. Tonseth said harvest requires a smaller number; estimating SARs requires a larger number.

B. Request for Broodstock to Expand Wells Hatchery Subyearling Production

In an email on July 15, 2019, Mike Tonseth outlined a request to the Wells HCP-HC to support the collection and spawning of an additional 350 adult hatchery summer Chinook salmon from the Wells volunteer channel to support an additional production of 500,000 subyearlings in brood year 2019 for the benefit of Southern Resident Killer Whales.

Tonseth said the decision being requested does not pertain to how to allocate surplus fish, but rather asks the Wells HCP-HC to approve that there is capacity at the Wells Fish Hatchery to accommodate rearing of the additional subyearling summer Chinook salmon.

Keely Murdoch said there are three issues with the request:

1. This should be a Joint Fisheries Parties (JFP) discussion.
2. The YN feels that existing programs such as the Yakima Basin summer Chinook salmon program should be filled prior to meeting new program needs. Earlier this year, the HC declined a request to send surplus summer Chinook salmon to the Yakima Basin program that perhaps should have been discussed not in the HC but in the JFP. The YN feels allocation of additional fish to the Yakima Basin is a better use for meeting the need of providing prey to Southern Resident Killer Whales.
3. The management considerations of additional fish returning to the upper Columbia Basin have not been considered, which is also a JFP issue.

Tracy Hillman asked if this is still an HC issue or should it be discussed and resolved by the JFP. Murdoch said there is inconsistency about how allocating surplus is handled in the HC and that is creating a conflict. Greg Mackey said the HC is responsible for approving documents and making decisions related to the PUDs' HCP programs. In the case of the Yakima Reintroduction program for instance, it is not an HCP-HCs or PRCC HSC program and allocation to the program should not be decided within the Committees setting. Tonseth said with regard to the HCs the nexus is that the fish would be reared at Wells Fish Hatchery. The allocation of surplus adult returns should be decided outside the HCP process.

Murdoch said that last week there was a discussion over email about planning for the approved uses of surplus fish from Wells Fish Hatchery, and now there is a sudden higher need outside of the approved surplus fish uses. Tonseth said this is not a higher need but an additional need that is a new legislative mandate. Murdoch said the intent of the mandates should be met, and can be met by allocating fish to the Yakima Basin, which has been permitted for this action. Wells Fish Hatchery has not been permitted for this action.

Bill Gale said the issue is about hatchery production at Wells Fish Hatchery. Gale said a concern is that there were proposals developed for rearing fish at Wells Hatchery without involvement of the HC. The proposals that were developed by Douglas PUD and WDFW should have gone through the HC prior to the time of broodstock collection. Proposals need to be discussed in Committee prior to planning.

Tonseth disagreed. Tonseth said WDFW reached out to multiple facilities to identify places where additional capacity would be available for rearing the fish. Tonseth said WDFW does not need approval to implement the program. Gale said they do if it involves Wells Fish Hatchery. Murdoch said only the element of whether there is capacity requires HC approval. Gale said it's not just about rearing capacity, it's also about whether this proposed program impacts the existing HCP programs.

Gale said a proposal should be created with more consideration than the existing email request.

Murdoch said there has to be concurrence by the JFP that the new proposed use of the surplus fish is the most beneficial use for the program.

Gale asked about bull trout permit compliance. Tonseth said that would be part of the permitting process. Gale asked if this is going to be proposed as a new program under *US v. Oregon*. Tonseth said no, because there is only funding for two years, so it is not WDFW's intent to include this program under *US v. Oregon*. Hillman asked if Brett Farman had a comment. Farman declined to comment on the issue of use of surplus fish. Murdoch said NMFS has been engaged regarding obtaining permits. Kirk Truscott asked what would happen if permits are not approved and there is a surplus at the juvenile stage. Tonseth said juveniles would be out-planted to non-anadromous waters.

Truscott said allocation of surplus adults to the tribes and collection of broodstock for this new proposal can be done concurrently. Tonseth agreed there appears to be enough surplus for all programs this year.

Catherine Willard asked whether the 500,000 juveniles needed is for one year or two years. Tonseth said the funding is for $175,000 per year, which roughly equates to rearing 500,000 subyearlings annually.

Truscott said last week over email he asked the HC to concur that there is now a surplus at Wells Fish Hatchery to allow for fairness in allocation to the programs receiving surplus.

Hillman said the issue is that there is no proposal for the HCP-HC to evaluate whether there is an effect on HCP production programs. Murdoch said the issue is that a proposal was developed but wasn't brought forward formally to the Wells HC. Hillman asked how quickly this needs to be resolved. Tonseth said the critical piece is having adults on hand and suggested having a brief discussion after the HCP HC meeting among WDFW, Douglas PUD, CCT, and YN members to establish a temporary path forward to ensure broodstock are not lost during a period in which WDFW develops a more formal proposal.

Murdoch said at Wells Hatchery there hasn't been space in the past and a formal resolution to that problem hasn't been provided. Tom Kahler noted that the hatchery has been under construction for approximately 5 years, and has limited space.

Todd Pearsons asked how this would affect downstream programs. For instance, how this would affect recalculation. Tonseth said smolts produced for the orca program should not be added into the mitigation obligation for operating the hydro-projects. Recalculation looks at SARs and total adult returns. Returns from the orca program would need to be subtracted from the number used for calculating SARs, otherwise they would count against survival through the projects.

Truscott said he has confidence that Douglas PUD has done a complete evaluation about rearing space; however, he hasn't heard whether this proposal would require removing a certain number of potential adult returns. The expectation is that it would, but this calculation hasn't been formalized.

WDFW, Douglas PUD, YN, and CCT convened during the lunch break to establish a short-term path forward for retaining broodstock.

Tonseth said WDFW will prepare a 1-page proposal for the Wells HC to outline the impacts of the additional subyearling production, which are expected to be negligible. Hillman said the Wells HC will then evaluate the proposal to ensure the proposal does not adversely affect the HCP production programs. Once there is agreement to the proposal, the JFP will determine the allocation of surplus summer Chinook salmon broodstock.

Truscott said CCT will expect advance notification from WDFW if a surplussing day will occur. Tonseth agreed that coordination will occur.

IV. Rock Island/Rocky Reach HC

A. Relative Reproductive Success Study Extension Memo Update

Catherine Willard said that in 2014, WDFW asked the Rocky Island HC to extend the scope of the Relative Reproductive Success (RRS) Study to include brood years 2014 through 2018. Mike Tonseth clarified that DNA sampling of adults would be required through 2023 for NOR fish; the juvenile DNA sampling would be terminated after 2019.

Bill Gale asked if the intent would be to sample 100% of the adults passing over Tumwater Dam. Willard said trapping at Tumwater would be consistent with the approved trapping operation plan at Tumwater Dam. Tonseth said this is mostly done during broodstock collection and adult management. Tonseth said fish are sampled for DNA, are PIT tagged, and then passed above the dam. Tonseth said although the Operating Plan allows for trapping 24 hours a day, trapping is not actually carried out 24 hours a day; there would still be some passage at night. Tonseth said this year's activities would be indicative of what will be done through 2023 for the RRS study. (*Note: On August 21, 2019, McLain Johnson [WDFW] confirmed via email to Catherine Willard and Mike Tonseth that the Tumwater Dam trap is currently being operated 24 hours a day)*.

Todd Pearsons asked how many NOR fish would be sampled. Tonseth said he didn't know. The intent is to sample as many as possible within the operating constraints. Pearsons said the issue is to ensure there is representative sampling.

Gale asked if the activities are contingent on funding. Tonseth said no, it is fully funded through 2023.

Peter Graf asked if juvenile sampling is continuing at the Wenatchee River screw trap. Tonseth said yes, sampling would occur through 2020 to capture the outmigrants.

The current RRS study extension memo requests the HCP-HC to approve the revised memo. Tonseth said there are additional clarifications needed in the memo. He will retract the memo, revise it, and resend it for review and approval during the August meeting.

V. PRCC HSC

A. Approve the May 15, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the May 15, 2019 meeting minutes as revised.

B. White River Memorandum Progress Update

Tracy Hillman reminded the PRCC HSC that he asked Denny Rohr for specific direction from the PRCC on the intent of the White River memorandum. Hillman has not yet received direction from the PRCC.

Keely Murdoch said the issue has been discussed in the PRCC but there remains some confusion over the original intent of the PRCC request to the HSC.

Scott Carlon (NMFS representative to the PRCC) invited Jeff Jorgensen (NMFS life-cycle modeler) to the PRCC meeting to discuss data needs for life-cycle modeling; however, Jorgensen is unavailable until September so the issue will be delayed until the September PRCC meeting. Murdoch suggested that members of the HSC attend to view Jorgensen's presentation and ask questions of him.

Bill Gale asked if anyone has heard from Craig Busack regarding his ability to re-engage with the group on this topic. Brett Farman will follow up with Busack.

Todd Pearsons asked if the HSC should develop some questions for Jorgensen for a more productive discussion. For instance, asking what data needs there are, to understand why certain existing data are insufficient.

Murdoch and Graf will make a request to the PRCC that HSC members participate in the September meeting for Jorgensen's presentation and that they are able to identify specific questions for Jorgensen prior to the meeting. Hillman will compile the questions to be sent to Jorgensen.

C. Finalize the Grant PUD 2020 M&E Implementation Plan for Wenatchee and Methow Basins

Todd Pearsons reviewed minor changes made to the draft "*Grant County PUD Hatchery Monitoring and Evaluation Implementation Plan for Spring and Summer Chinook in the Wenatchee Basin and Summer Chinook in the Methow Basin 2020*."

Pearsons identified one substantive change. Pearsons said forced releases limit their ability to use PIT tags to monitor releases at Carlton Pond and Nason Acclimation Facility. Kirk Truscott asked if there are predation problems that affect calculation of survival of the fish reared at Carlton Pond. Pearsons said no.

Mike Tonseth asked to review a passage on residualism. Pearsons updated a section of estimating residualism by monitoring PIT-tag detections post-release. Tonseth said there should be language consistent with draft permits for pre-release sampling; an edit may not be needed in this document as long as there is an understanding that what was written in the permits will be implemented.

Tracy Hillman asked the PRCC HSC to vote on the Priest Rapids M&E plan; all parties approved.

VI. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are August 21, 2019, September 18, 2019, and October 16, 2019, at Grant PUD in Wenatchee, Washington.

Bill Gale asked if there are agenda items for the PRCC HSC meeting in August such as broodstock protocol issues. Mike Tonseth said there was not a proposal for real-time otolith reading to be discussed, and there is now an alternative strategy in use so PRCC HSC broodstock protocols will not be modified.

CONTROL OF *SAPROLEGNIA* SP. GROWTH ON SUMMER CHINOOK (*ONCORHYNCHUS TSHAWYTSCHA*) EGGS

EXPERIMENTAL PROTOCOL – PILOT STUDY

WELLS HYDROELECTRIC PROJECT

FERC NO. 2149

May 21, 2019

Prepared by:
Dr. Betsy Bamberger
DCPUD Fish Health and Evaluation Specialist

Public Utility District No. 1 of Douglas County
East Wenatchee, Washington 98802

ABSTRACT

Summer Chinook (*Oncorhynchus tshawytscha*) eggs were treated with hydrogen peroxide, sodium chloride (salt), formalin, and ambient water for the prophylactic management of Saprolegniasis (water mold infestation) at Methow Fish Hatchery (MFH) in Winthrop, Washington. This pilot study detected no difference in apparent effect on viability or survivability of eggs and alevins among the treatments described. However, the relatively few number of water mold-infected eggs in the treatment groups suggests *Saprolegnia* sp. was present in the water supply in insufficient amounts to cause substantial infection, pathology, and/or loss. This result questions the historic and future need for preventative measures to be implemented for "fungus" control during egg incubation at MFH.

1.0 INTRODUCTION

Water mold (*Saprolegnia* sp.) is a common pathogen of salmonid eggs in fish hatcheries. Traditionally, hatcheries have used formalin for prophylactic management of *Saprolegnia* sp. infection in incubating eggs. However, formalin has long been associated with worker safety and environmental hazards, and is expected to be met with increasing scrutiny by regulatory agencies in the immediate future. In this study, we investigate the efficacy of purported alternatives to formalin that can be used as safe therapeutic substitutes. These alternatives include hydrogen peroxide (H_2O_2) and salt (NaCl), as well as no treatment (i.e., ambient water only), in controlling water mold infestations during salmonid egg incubation under typical hatchery conditions at the Methow Fish Hatchery (MFH) (located in Winthrop, Washington). The study described here is a pilot study to develop and evaluate the mechanics of delivering treatment and to gain preliminary results to guide future work. We tested the null hypothesis that there will be no difference found among test treatment groups (hydrogen peroxide, sodium chloride, no treatment [water]) and the formalin group, using egg mortality caused by Saprolegniasis as the basis for the analysis.

2.0 METHODS

Twenty-four (24) females and fourteen (14) males of Wells Hatchery-origin (hatchery) summer Chinook were collected at Wells Fish Hatchery (WFH) in mid to-late July, 2018. Once sexually mature, the adult fish were stripped of eggs and milt at WFH on October 16, 2018. All gametes were harvested on the same day to eliminate temporal bias. Once all were harvested, green eggs and ovarian fluid from spawned females were collected directly into a communal, approximately 65 L plastic tub, and gently mixed to control for potential maternal effects across the treatments. Eggs were then divided into twenty-four approximately equal portions (each deposited into a separate, numbered large Ziploc® bag) and placed in an ice-filled cooler lined with burlap. Milt from each male was collected in separate, small Ziploc® bags and stored in the same chilled cooler. Later that same day, all gametes were transported to MFH, approximately a one hour drive away. Upon arrival at MFH, the unfertilized eggs were split into two sets of twelve (each bag of eggs deposited into a separate plastic bucket) to accommodate the hatchery staff's preferred work methods. The eggs were combined with the milt from an individual male, used for primary fertilization, and then milt from a second male used as backup several minutes after initial fertilization by the primary male. Each male served as a primary male for at least one female and a backup male for one or more females, thus providing greater probability of successful fertilization and allowing identification of an individual male with reduced viability or non-viable gametes. All eggs were mixed prior to fertilization so detection of an individual female with reduced viability or non-viable eggs was not possible.

Eggs and milt were stirred together, gently rinsed with water, and then placed in a designated individual Heath vertical incubator tray and within a stack assigned to one of four treatment groups (formalin, salt, hydrogen peroxide, and water [no treatment]).

Eight incubation stacks were used, two for each of the four treatment groups. The topmost tray of each stack was kept empty to allow for ease of chemical introduction; three staggered trays below were reserved for eggs (see treatment-specific information and schematic representation of experimental set-up in Figure 1, below). The formalin stacks were located in a separate incubation room to avoid potential adverse chemical reactions between formalin and hydrogen peroxide, but otherwise the stacks and trays were identical to the other treatments. Each tray was numbered in advance to identify treatment type and tray position in the stacks. Egg clutches were placed within trays in sequential order until all trays were occupied. For all treatments, the fertilized eggs in the trays within the stacks were water-hardened and disinfected in a 100 ppm buffered iodophor (Ovadine®) solution (static bath) for 60 minutes. Following water hardening and surface disinfection, fresh well water (averaging 8°C, [47°F]) was introduced into the stacks, effectively draining away the used iodophor solution from each tray. Flow was set at 3 gallons per minute (gpm) except in the salt treatment stacks, where it was set at 3.2 gpm to accommodate the added volume of saline solution to be introduced into the system.

Formalin, salt, and hydrogen peroxide were added to the topmost (empty) tray of the incubation stacks and delivered via a metered peristaltic pump (INTLLAB™ or MasterFlex easy-load® II). Dosages of hydrogen peroxide, formalin, and salt were calculated to consider flow rate, treatment time, final desired concentration of chemical treatment, and chemical strength. As such, treatments were consistent with FDA-label instructions or previously published data (see Figure 1). Salt was pre-dissolved before administration; salinity was monitored during treatment with an Apera 5052 saltwater salinity tester with the probe placed in the topmost empty tray and recorded at multiple time points during administration (0, 5, 10, 15, and 20 minutes).

Daily 15-minute flow-through treatments with hydrogen peroxide, well water, and salt were initiated on the day following fertilization (October 17, 2018). Treatments continued on alternate days until November 22, 2018, providing 19 days of treatment, and ceased just prior to the initiation of hatching. Formalin treatments were administered on the second day following fertilization (October 18, 2018) to avoid undesirable exposure to other oxidizing compounds used in this study, and continued on alternate days until November 23, 2018, providing 19 days of treatment.

A total of 975 mL of hydrogen peroxide and 1,539 mL of formalin were used for each treatment day (volume accounts for both treated stacks). Salt concentrations varied during treatments before stabilizing but reached above 30 ppt on Oct 17th, Oct. 19th, Oct. 27th, Oct 29th, Nov 6th, and Nov 18th for 5-10 minutes.

On November 24, 2018, the incubator trays in the hydrogen peroxide, well water, and salt stacks were opened and eggs photographed; the eggs were shocked by mechanical agitation within the trays and then dead eggs were removed and counted before trays were returned to the stacks. The same occurred on November 25, 2018 for the formalin group (photographed on November 26, 2018). On November 27, 2018, five live eggs from each treatment group (trays 1-4) were fixed in 10% neutral buffered formalin and sent to the Washington Animal Disease Diagnostic Laboratory (WADDL) for histological analysis.

On December 1, 2018, the trays for all groups were again opened and any dead and *Saprolegnia*-infected eggs were removed by hand and counted. An average individual egg weight was estimated from a 100 egg sample of the remaining live eggs in each tray that were carefully dried (via Wypall shop towels) and weighed. This total dried egg weight from each female was divided by the average egg weight to estimate the number of live eggs for each tray (note: total weights were reduced by 3% to approximate the weight of residual water). All trays were disinfected with Ovadine® for 10 minutes at 100 ppm before being placed back in the stacks.

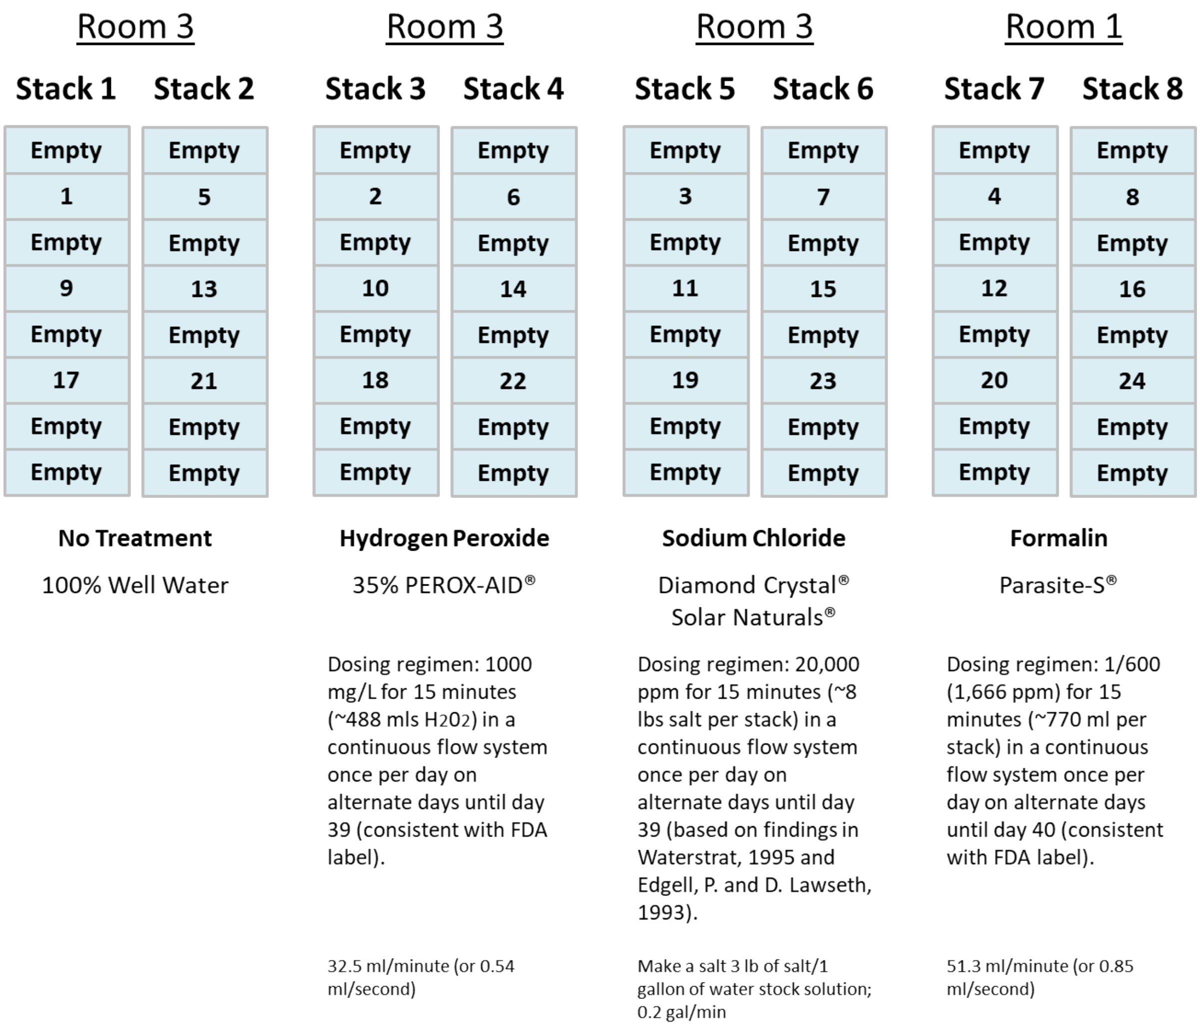

Figure 1: **Schematic representation of incubation room, stack and tray assignment, and dosing regimen per treatment group.**

Fifty (50) eggs from each tray were combined into one tray for each treatment group (5th tray from the top in stack 7, and 7th tray from the top in stacks 1, 3, and 5) on December 8, 2018 and incubated until the alevin stage (50 eggs x 6 trays per treatment group = 300 per group x 4 groups = 1200 eggs total). All other remaining eggs were destroyed, per the study design.

Mortality from eyed egg to unfed fry for each treatment was assessed when the unfed fry were determined to be near ponding readiness on January 22, 2019. Staff checked for discernable morphological differences in unfed fry from each group to determine if histological analysis was warranted.

All alevins were destroyed before the first feeding, per the study design.

The criteria used to evaluate the efficacy of each compound was mortality from fertilization through eyed egg (which includes both water mold-infected eggs and dead uninfected eggs throughout the 40 day incubation period and after shocking) and eyed egg to unfed fry survivability. In addition, the extent of water mold infection was qualitatively (via photography) and quantitatively (via the number of eggs that appear infected) estimated and enumerated, respectively.

3.0 STATISTICAL ANALYSIS

One-way ANOVA was used to examine similarities or differences between treatment groups. We verified that the assumptions (equal sample sizes, independence, etc.) were maintained in order to justify the application of the ANOVA. Further, in order to verify that tray position had little or no influence on experimental results, we compared mean egg survival to the eyed egg stage (%) against tray position number within each stack using a one-way ANOVA. Further, to insure there was no interaction between tray position and treatment, we ran a 2-WAY ANOVA using these predictors and percent egg loss as the response variable. P-values were assessed at $\alpha = 0.05$. Had the response variable not satisfied the assumption of homogeneous variance, an alternative analysis such as beta regression would have been used. All statistical analysis was conducted in JMP (8.0.2 SAS Institute Inc.).

4.0 RESULTS

All treatments had high average egg survival in excess of 92.9%, suggesting that there was little difference among the treatments (Figures 2-8 and Table 1). The vast majority of egg mortality occurred between fertilization and the eyed egg stage, accounting for approximately 95% of total egg loss. Conversely, less than 5% of all egg loss occurred between the eyed egg stage and emersion from the egg (first and second picks).x Similarly, the survival of alevins revealed no difference among treatments (Table 2). Notably, the no treatment (water only) group was not statistically different from the other treatment groups during the egg or the alevin stages of the study.

Upon opening the trays to assess mortality and perform the first pick, a scant amount of grey flocculent material (*Saprolegnia* sp. mycelia) was found surrounding white-to-tan (nonviable) individual eggs in trays 1 (two eggs), 9 (two eggs), 17 (four eggs), and 21 (four eggs) of the no treatment group; 10 (three eggs), 18 (three eggs), and 22 (one egg) of the hydrogen peroxide group; and 19 (one egg) and 23 (one egg) of the salt group (see Figure 6). These eggs were readily apparent at first glance and situated on top of the egg pile; the trays were not mixed or otherwise disturbed to ascertain if any affected eggs were hidden. No eggs were observed to be infected in the formalin group.

Total mortality per sample (tray) ranged from 4.22-9.28% regardless of treatment. One-way ANOVA verified that there were no significant differences between treatment groups when we examined average percent loss in each treatment ($p = 0.66$, $df = 3$, $f\ ratio = 0.55$; Figure 2).

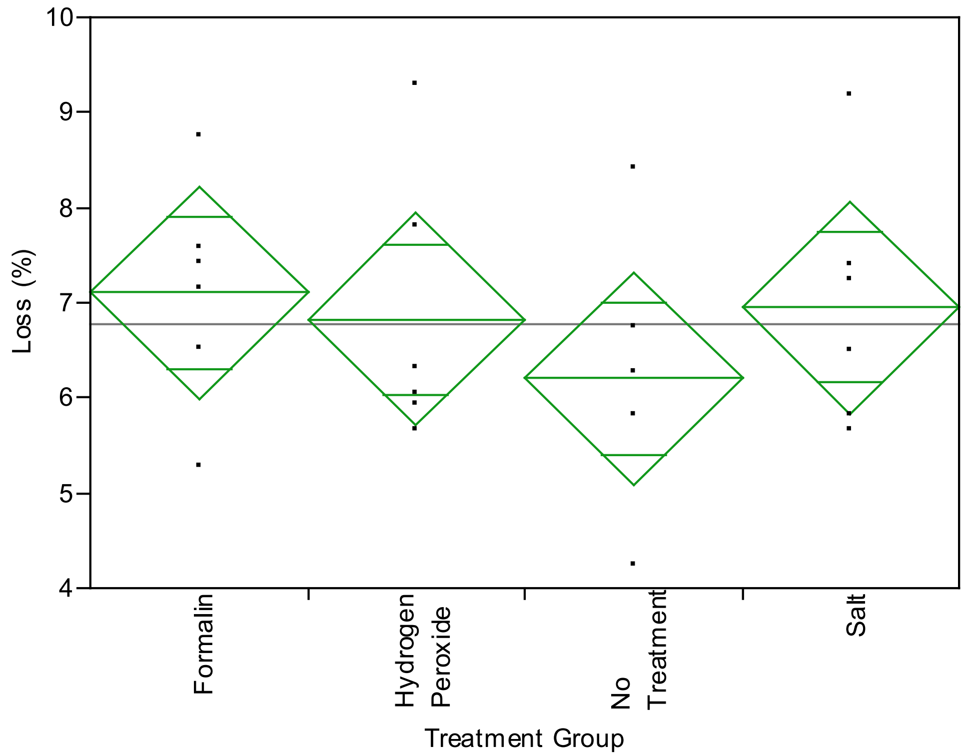

Figure 2. **One-way ANOVA comparing total egg loss as a percentage of available eggs (y-axis) for each treatment group (x-axis). Green triangles represent 95% confidence intervals, the middle green line represents the group mean, and the gray horizontal line represents the mean of all replicates regardless of treatment. Results were somewhat variable within each treatment group and, as such, no significant differences were observed. (*p* = 0.66, *df* = 3, *f ratio* = 0.55).**

To test that our handling procedures, or in this case the order of tray placement, did not influence egg survival, we examined tray location category with average egg loss at those positions (%). This ANOVA yielded no relationship ($p = 0.59$, $df = 2$, $f\ ratio = 0.55$, $\eta^2 = 0.082$; Figure 3), giving us confidence that tray position was unimportant in predicting egg loss and our husbandry of trays was appropriate. Finally, our 2-way ANOVA that used tray position and treatment as predictor variables that may interact with each other to have an effect on percent egg survival yielded no interaction ($p = 0.48$, $df = 6$, $f\ ratio = 0.96$, $\eta^2 = 0.75$).

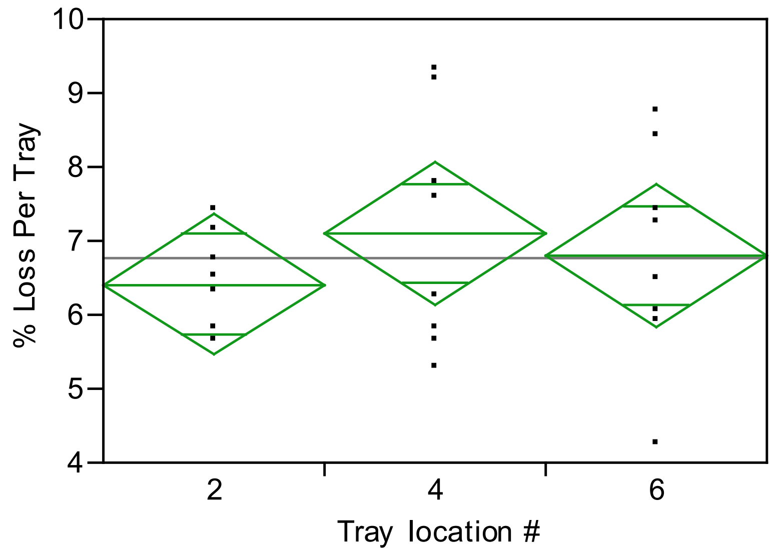

Figure 3. **One-way ANOVA comparing average total egg loss as a percentage of available eggs (y-axis) relative to tray location (x-axis). Green triangles represent 95% confidence interval, the middle green line represents the group mean, and the gray horizontal line represents the mean of all replicates regardless of treatment. Results suggest tray location did not influence egg loss (p = 0.59, *df* = 2, *f ratio* = 0.55, η^2 = 0.052).**

Hydrogen Peroxide	22-Jan	3	6
Salt	22-Jan	2	4
Formalin	22-Jan	1	2

5.0 DISCUSSION

There was no significant difference in survival among treatment groups to the eyed egg or the alevin stages. The spatial pattern of loss within trays, as evidenced by the photos taken after shocking, was more or less consistent between trays. Most often, nonviable eggs were evenly distributed throughout the tray, indicating that mortality was ostensibly sporadic and not necessarily associated with pathogen epicenters or water flow irregularities. The two exceptions were trays 10 (hydrogen peroxide–treated group) and 20 (formalin-treated group) with dead eggs clumped in the center of the trays. The phenomenon may have been coincidental. The egg/alevin losses were almost negligible and consistently low among all groups. The relatively few numbers of water mold-infected eggs suggests *Saprolegnia* sp. was present in the water supply in insufficient amounts to cause substantial infection, pathology, and/or loss. This result questions the historic and future need for preventative measures to be implemented for "fungus" control during egg incubation at MFH.

In 2015, the percent survival of unfertilized egg-eyed was 96.1 and 98.8 for the Methow Composite spring Chinook and Twisp spring Chinook, respectively, while in the Wells summer Chinook yearling program (reared at WFH and the source of the eggs used in this study) the percent survival of unfertilized egg-eyed was 90.0. The mean percent survival of brood years 1999 through 2015 was 95.0 and 94.2 for the Methow Composite spring Chinook and Twisp spring Chinook, respectively. The egg survival percentage in this study (on average equal to or in excess of 92.9% for all treatments) is comparable to those historically recorded at Methow, if slightly lower. This disparity may be attributable to the difference in stock (summer versus spring-run Chinook), incubation vessel (trays versus the standard isolation buckets used at the hatchery), or quality of eggs (study eggs were attained near the tail-end of the spawning season at Wells Hatchery and underwent additional handling during transport to Methow Hatchery). Compared to the egg mortality rates at Wells, the eggs in this study had slightly higher survival, but it is difficult and perhaps unproductive to compare losses across facilities with different water sources, set-ups, and other variables.

The chemicals themselves appear to have made little impact on the eggs in terms of survivability. Indeed, the eggs collected and submitted on November 27, 2019 for histological analysis were found to have no differences in cellular structure (see Attachment 1 for the report from the Washington Animal Disease Diagnostic Laboratory). Hatchery staff did notice that the formalin-treated eggs felt the "hardest" (re: most rigid) among all groups and that the salt-treated eggs were perceived to be the tackiest. Additionally, when trays were tapped (presumably to better sift through and inspect the eggs within), the eggs in the hydrogen peroxide, salt, and no treatment groups did not move within the trays as effortlessly as was thought to be normal for formalin-treated eggs. The hatchery staff also noted that the eggs in the salt treatment group hatched a day or two early; it is theorized that the saline mixture dissolved in hot water the day before may have warmed the ambient well water in the salt-treated stacks and influenced the rate of development in treated eggs. This seems unlikely but no other explanation to account for this observation is readily apparent.

6.0 CONCLUSION

There was no appreciable difference in egg mortality or hatch-out viability between treatment groups. There was no apparent effect on viability or survivability of eggs and alevins associated with the treatments described. Notably, the use of ambient water (i.e., no treatment) was as effective as treating with any of the three chemicals tested, suggesting that in some situations chemically treating eggs may not be necessary to achieve high survival during egg incubation at MFH. However, it is unclear if the treatments attempted in this pilot would control *Saprolegnia* sp. infestations if tried in a system with infectious levels of pathogen present.

Future work should include conducting a similar study in a facility with a greater likelihood of high levels of *Saprolegnia* sp. A follow-up pilot study is planned for the fall of 2019 at MFH. Untreated spring or summer Chinook eggs (if available) will be incubated in isolation buckets and compared to formalin-treated eggs of the same run reared in similar containers. Based on the findings found here, it is hypothesized that there will be no difference in egg mortality and hatch-out survivability between the two groups. These findings could help inform future egg management strategies and reduce chemical use at MFH.

Another follow-up study will be attempted on summer Chinook in the fall of 2019 at WFH, where levels of *Saprolegnia* sp. may be higher. The study protocol will greatly resemble this one with provisions and accommodations appropriate for that facility.

7.0 ACKNOWLEDGEMENTS

Special thanks to the Methow Fish Hatchery staff (Brandon Kilmer, Dave Dinsmore, Matt Moore, and Emily Vinge); Greg Mackey and Andrew Gingerich for their help in completing this pilot study; and review by Tracy Hillman.

Histopathology Report

Embryonated summer chinook salmon eggs from 4 treatment groups are received fixed in formalin. Eggs are bisected and processed into 4 slides for histologic examination as follows:

- Slide 1. Hydrogen peroxide
- Slide 2. No treatment
- Slide 3. Formalin
- Slide 4. Salt

All eggs are histologically similar and unremarkable.

HISTOLOGIC DIAGNOSIS:

1. Histologically normal embryonated eggs (see comments)

COMMENTS: There was no discernable difference between the treatment groups on histologic examination. However, the lack of histologic changes does not necessarily rule out functional or physiological differences or viability between groups. Chemical changes (e.g. on yolk proteins and lipid) associated with different treatments may not result in a corresponding histologically appreciable change.

Re: Final Minutes of the August 21, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

---

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, August 21, 2019, from 9:00 a.m. to 1:15 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*
- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*
- Tracy Hillman and Larissa Rohrbach will add review of the Broodstock Collection Protocols (BCPs) to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item II-F). *(Note: this item is ongoing.)*
- Greg Mackey will distribute a white paper reviewing broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A). *(Note: this item is ongoing.)*

Re: Final Minutes of the August 21, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, August 21, 2019, from 9:00 a.m. to 1:15 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*
- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*
- Tracy Hillman and Larissa Rohrbach will add review of the Broodstock Collection Protocols (BCPs) to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item II-F). *(Note: this item is ongoing.)*
- Greg Mackey will distribute a white paper reviewing broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A). *(Note: this item is ongoing.)*

- Larissa Rohrbach will add HCP Policy Committee guidance on policy-level issues to the HCP-HC Meeting Protocols (version dated May 15, 2019; Item I-A).
- Catherine Willard will update the genetics section of the *Monitoring and Evaluation Plan for PUD Hatchery Programs (Update to the 2017 Plan)* to reflect revisions that were suggested in the August 21, 2019 meeting (Item II-D).

PRCC Hatchery Subcommittee

- HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item I-A). (*Note: This item is ongoing.*)
- Brett Farman will ask Craig Busack (National Marine Fisheries Service [NMFS]) to participate in the Wenatchee Basin life-cycle modeling discussion at the PRCC meeting on September 25, 2019, at Wanapum Dam, Washington (Item V-B).

Decision Summary

- Larissa Rohrbach sent an email to the Wells HC on September 11, 2019, noting that all parties voted by email in concurrence that there is sufficient capacity at Wells Fish Hatchery for WDFW’s additional production of subyearling Chinook salmon for southern resident orca prey, without compromising the existing, on-station HCP programs (Item III-A).

Agreements

- There were no agreements made in today’s meeting.

Review Items

- Larissa Rohrbach sent an email to the Rock Island and Rocky Reach HCP-HCs on August 21, 2019, notifying them that WDFW’s revised *Relative Reproductive Success Study Extension Memorandum* (RRS memorandum) is available for review and approval in the September 18, 2019 meeting (Item II-A).
- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on August 19, 2019, notifying them that Douglas PUD’s *2019 Egg Treatment Study Plan* is available for review and approval in the September 18, 2019 meeting (Item II-B).
- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on August 21, 2019, notifying them that the revised *Broodstock Collection Protocols Development Timeline Statement of Agreement* (SOA) is available for review, with edits due to Mike Tonseth by September 6, 2019 (Item II-F).

- Larissa Rohrbach sent an email to the Rock Island and Rocky Reach HCP-HCs on August 21, 2019, notifying them that *Chelan PUD's 2020 Draft Monitoring and Evaluation Implementation Plan* is available for review, with edits due to Catherine Willard by Friday August 30, 2019 (Item IV-A).

Finalized Documents

- There were no documents finalized in today's meeting.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the July 17, 2019 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and asked for any additions or changes to the agenda. Greg Mackey asked to remove Item II-D, "Alternative broodstock composition and mating strategies," to prepare for more discussion in a future meeting. Bill Gale asked to add a fish health update for Leavenworth National Fish Hatchery (LNFH) to the Joint HCP-HCs and PRCC HSC topics (new Item II-C). The HCP-HCs and PRCC HSC members approved the agenda as revised.

The HCP-HCs and PRCC HSC representatives reviewed the revised July 17, 2019 meeting minutes. Larissa Rohrbach said there were some revisions that the representatives then reviewed. Additional revisions were made in the meeting. The HCP-HCs and PRCC HSC members approved the July 17, 2019 meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on July 17, 2019, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on July 17, 2019)*:

Joint HCP-HCs and PRCC HSC

- *Tracy Hillman will review aspects of the Independent Scientific Advisory Board's Review of Spring Chinook Salmon in the Upper Columbia River under HCP-HCs' purview (Item I-A).*
  Hillman said this item is ongoing. Hillman said his contract is set up to prepare the 10-year Comprehensive Reports and then move on to updating the PUDs' Monitoring and Evaluation Plan (M&E Plan; Update to the 2017 Plan) per the Independent Scientific Advisory Board's guidance. Hillman requested that this action item be set aside until he re-initiates work to update the M&E Plan. Greg Mackey said the M&E Plan must be updated every 5 years and updates should be brought to the HCP-HCs for consideration at that time. This item will be removed from the action items list.

- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A).*
  Tonseth said this item is ongoing, pending additional information from Jeff Jorgensen (NMFS).
- *Catherine Willard will update the genetics section of the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (Update to the 2017 Plan) based on the genetics panel recommendations and will append the recommendations from the panel to the plan (Item I-A).*
  The 2017 PUDs' M&E Plan was updated by Willard and distributed by Sarah Montgomery via email on August 9, 2019. This item will be discussed in today's meeting. This item is complete.
- *Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A).*
  Truscott said this item is ongoing.
- *Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A).*
  Farman said this item is ongoing. In the July HCP-HCs meeting Farman noted NMFS's approval for use of the iterative approach of estimating PNI for annual M&E reporting; however, the use of the multi-population model has not been discussed with his NMFS colleagues.
- *Mike Tonseth will revise the* Relative Reproductive Success (RRS) Study extension agreement memorandum *for clarity (Item II-A).*
  Tonseth said this item will be discussed in today's meeting. This item is complete. *(Note: the revised memorandum was distributed immediately following the meeting for review.)*
- *Larissa Rohrbach will add sizing of upper Columbia River conservation programs as a periodic agenda item (Item I-A).*
  Rohrbach said this item is complete. Rohrbach said a schedule for the next discussion of this topic will be determined in today's meeting (Item I-F).
- *Tracy Hillman and Larissa Rohrbach will maintain a list of outstanding topics, as follows, for consideration in HCP-HCs and PRCC HSC meetings prior to development of the 2020 Broodstock Collection Protocols (Item II-F). (Note: this item is ongoing.)*
  - *Use of age-3 males in broodstock*
  - *Use of alternative mating strategies*
  - *Establishing ranges around broodstock collection targets*
  - *Source for Chiwawa spring Chinook salmon broodstock*

Rohrbach said this item is complete. Rohrbach said a schedule for the next discussion of this topic will be determined in today's meeting.

- *Tracy Hillman and Larissa Rohrbach will add review of the Broodstock Collection Protocols to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item I-A).*
  Rohrbach said this item is ongoing.
- *Mike Tonseth will revise and redistribute the HCP-HCs Annual Broodstock Collection Protocols development timeline Statement of Agreement (SOA; Item II-F).*
  Tonseth said this item will be discussed in today's meeting. *(Note: the revised SOA was distributed immediately following the meeting for review.)*
- *Mike Tonseth will ask Michael Humling (U.S. Fish and Wildlife Service [USFWS]) and Charlie Snow (WDFW) to estimate the number of Methow returns that are likely to return to Winthrop National Fish Hatchery to inform a translocation discussion in a future HCP-HCs meeting (Item I-A).*
  Tonseth said this item is ongoing. Larissa Rohrbach said a schedule for the next discussion of this topic will be determined in today's meeting (Item II-F). This item will be removed from the action item list.
- *Mike Tonseth will revise and redistribute the 2017 Out-planting Surplus Methow Composite Spring Chinook Salmon Adults memorandum (Item I-A).*
  Tonseth said this item is ongoing. Larissa Rohrbach said a schedule for the next discussion of this topic will be determined in today's meeting (Item II-F). This item will be removed from the action item list.
- *Larissa Rohrbach will add HCP Policy Committee guidance on policy-level issues to the HCP-HC Meeting Protocols (version dated May 15, 2019; Item I-A).*
  Tracy Hillman said this item is ongoing, pending finalization of the July 23, 2019 HCP-Coordinating Committee meeting minutes.
- *Betsy Bamberger and Greg Mackey will distribute a draft 2020 study plan for The Control of Saprolegnia Sp. Growth on Summer Chinook (Oncorhynchus tshawytscha) Eggs (Item II-B).*
  Bamberger and Mackey distributed the draft 2020 study plan, as distributed by Larissa Rohrbach via email on August 19, 2019. This item is complete.
- *Greg Mackey will distribute a white paper reviewing broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A).*
  Mackey said he prepared a draft white paper that he recently edited and sent to a few HC members for review. He will prepare a presentation and distribute a revised version of the white paper for a future HCP-HCs meeting.

Wells HC

- *Mike Tonseth will prepare a proposal for the Wells HCP-HC on the use of surplus summer Chinook collected from the Wells Volunteer Trap for the production of subyearling smolts to support the Southern Resident Killer Whale population (Item III-A).*
  Tracy Hillman said Tonseth sent this updated proposal and a request for the Wells HC to vote in concurrence that sufficient capacity exists at Wells Fish Hatchery via email to Larissa Rohrbach and Hillman on August 20, 2019. This topic will be discussed in today's meeting. *(Note: the proposal and request for vote via email was distributed by Rohrbach immediately following the meeting.)*

PRCC Hatchery Subcommittee

- *HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item V-A).*
  Hillman said he has not received any responses from PRCC HSC members yet.
- *Keely Murdoch and Peter Graf will ask the PRCC whether members of the HSC can participate in the PRCC meeting when Jeff Jorgensen (National Marine Fisheries Service [NMFS]) discusses the Wenatchee life-cycle model and data needs (Item V-A).*
  Graf said the PRCC agrees the HSC members can attend the discussion with Jorgensen during the next PRCC meeting on September 25, 2019, at Wanapum Dam. This item is complete.
- *Tracy Hillman will compile questions from the PRCC HSC for Jeff Jorgensen during the August 21, 2019 PRCC HSC meeting (Item V-B).*
  Hillman said this item will be addressed in today's meeting. Hillman asked if Craig Busack is still interested in engaging with the HSC regarding the White River program. Brett Farman said he will ask Busack. Hillman suggested inviting Busack to participate in the conversation with Jorgensen in the September 25, 2019 PRCC meeting at Wanapum Dam.

II. Joint HCP-HCs and PRCC HSC

A. *Relative Reproductive Success Study Extension Memorandum* Update

Mike Tonseth provided the revised RRS memorandum via email and Tracy Hillman projected it for review during the meeting. Tonseth said the revisions included updating dates and updating language about the need for approval. The most important update is to note the last year of juvenile sampling is 2020 and the last year of adult sampling is 2023. Hillman asked if revisions to this memorandum need to be approved today. Tonseth said the memorandum states that WDFW requests approval from the Rock Island HCP HC for the clarifications in scope. Larissa Rohrbach will distribute the revised memorandum following the meeting for review. Bill Gale asked if discussion and the vote whether to approve the revisions could be delayed to the September HCP-HCs meeting. Tonseth said yes, the activities were already implemented in 2019, so approval of revisions would pertain to activities in 2020 and beyond. Tonseth said the memorandum was directed at the Rock Island committee because the Rock Island HCP utilizes Tumwater Dam's fishway and trapping facilities. Catherine Willard said both the Rock Island and Rocky Reach HCPs utilize Tumwater Dam's fishway and trapping facilities.

B. *2019 Egg Treatment Study Plan*

Betsy Bamberger said in last month's meeting the 2018 Egg Treatment Study results were reviewed. The proposed 2019 study at Wells Hatchery is very similar to what was done at Methow Fish Hatchery last year with minor changes. One new treatment group was added: placing copper-covered pot scrubbers in the egg trays. The proposed list of treatment groups are as follows:

- Elemental copper
- Formalin
- Hydrogen peroxide
- 2% salt
- Ambient water (control)

The same dosages as were used last year at Methow Fish Hatchery would be used in 2019. There would be 5 egg stacks (1 stack per treatment) holding eggs from 7 females per stack. The eggs from a total of 35 females would be required and likely to require milt from 35 males with a 1:1 mating.

Bamberger said copper pot scrubbers are laid in the topmost egg tray of the treated stack. Over time the elemental copper leaches out of the pot scrubber and has an antimicrobial effect similar to other copper-based treatments like copper sulfate.

Bill Gale asked if the leaching of the copper depends on water quality. Bamberger said it is very dependent on water quality and she theorizes the effect may depend on the location of the hatchery relative to its water supply or that the effect will change over time.

Gale asked, at the production scale, what the effluent quality or National Pollutant Discharge Elimination regulation concerns are related to discharging copper into the Columbia River. Bamberger said they have discussed concerns with the Washington State Department of Ecology (Ecology) and they did not know of any restrictions on copper in effluent. Bamberger said in Idaho where Idaho Fish and Game hatcheries are implementing production-scale use of the copper pads, the discharge of copper in effluent was well below limits. Bamberger said Ecology does not necessarily have a method for categorizing this type of effluent.

Greg Mackey said this approach cannot be used to treat alevins due to its toxicity to fish after they have hatched.

Kirk Truscott said one concern is whether the copper may be toxic to the eggs as well, and if this treatment is scaled up, toxicity to eggs should be considered. Truscott said another concern is the potential effect of copper on homing. He said some heavy metals can interfere with homing fidelity. Bamberger agreed these are valid concerns. She said in Idaho the copper pads were used on resident trout [not on anadromous species that home to a natal stream]. She said the first step would be to test the method to find out if it even works. She said Idaho Fish and Game did some work to look at whether the copper is absorbed by the egg [embryo] and found it is only absorbed into the chorion. Gale asked if anyone has tested the copper mats with anadromous species. Bamberger said she is only familiar with its use with resident trout.

Gale asked how many eggs would be used. Bamberger said all the eggs from 35 females would be used regardless of the exact number. Truscott asked if all eggs would be destroyed except for those treated with formalin. Mackey said the hatchery-production fish would be used as the formalin-treated group because formalin treatment is the typical treatment at this time and the other groups would be housed separately and destroyed at the end of the experiment. Bamberger said the eggs treated with copper should be destroyed because of FDA regulations.

Tracy Hillman asked if Douglas PUD would like approval of the study plan from the Wells HCP-HC. Mackey said it would be acceptable to ask for approval in the September meeting.

C. Leavenworth National Fish Hatchery Fish Health Update

Bill Gale asked to provide a fish health update about Leavenworth National Fish Hatchery. Gale said the hatchery is experiencing a columnaris disease outbreak in its spring Chinook salmon broodstock. He is not sure of exact numbers of fish affected but 27 adults died yesterday; fewer died today. He said these were fish that were not actively spawning yet. He said many fish have been spawned that would have died [if they were not taken for spawning]. Gale said USFWS is asking if any HCP-HC and PRCC HSC members have experience treating columnaris. Kirk Truscott asked how USFWS is currently treating the fish. Gale said the disease is affecting predominantly the males. He said the water temperatures can only be brought as low as 54°F. Catherine Willard said one fish that was collected for the Chelan Falls summer Chinook program exhibited signs of columnaris. She said it was returned to the river and was not brought to Eastbank Hatchery. However, Eastbank Hatchery is treating the fish prophylactically with Diquat as a preventative measure. Gale said USFWS was surprised because they haven’t seen it in a long time and haven’t had to treat it at LNFH. Betsy Bamberger said the well-water at Wells Fish Hatchery is also 54°F and she was also surprised to see the disease at this low temperature.

Bamberger suggested using chloramine-T and oxytetracycline as early treatments. Bamberger said once the disease is expressed, the disease may be beyond the phase when these treatments are effective. Bamberger said she prefers using Diquat to treat columnaris to minimize handling. Bamberger said that Douglas PUD has treated their summer Chinook salmon with Diquat.

D. Genetics Updates to the Monitoring and Evaluation Plan for PUD Hatchery Programs

Tracy Hillman reminded the committees that Catherine Willard took on the task of incorporating feedback from the invited panel of geneticists (provided in a memorandum dated December 13, 2018) into the genetic monitoring objective in the PUDs' M&E Plan (Update to the 2017 Plan).

Willard said the three PUDs are planning to conduct the genetic analyses for the 10-year Comprehensive Report. She said not all of the objectives in the genetics section of the M&E Plan were relevant to the current conservation programs and the objectives did not address the potential for changes in genetic diversity in natural populations as a result of a hatchery program. Willard worked with Todd Seamons (WDFW geneticist) to ensure her revisions were accurate.

Willard said the major changes were as follows:

1. An evaluation of linkage disequilibrium was added.
2. Beginning with brood years 2017 and 2018, testing of statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) will be conducted with natural-origin baseline samples (the earliest genetic samples available for each program) and natural-origin contemporary samples. Testing will be repeated every ten years (approximately two generations). If significant differences between baseline samples and contemporary samples are found, contemporary hatchery-origin samples will be analyzed to evaluate if the difference can be attributed to the hatchery programs.

Seamons proposed the stepwise approach for analyzing hatchery-origin samples only if there is a deviation observed between the contemporary natural-origin fish and baseline natural-origin fish.

Kirk Truscott asked if DNA samples would be archived for every brood year. He said a concern might be that if this analysis is carried out only every 10 years, a major change could be observed that could have been headed-off earlier with a change in operations. He suggested there may be incremental changes in allele frequencies that could be observed with more frequent analysis. Willard said the original question was whether hatchery programs are affecting the natural population. She said Truscott's question may be an additional question. Truscott said this may be a different question of minimizing risk of hatchery operations to the natural populations. Truscott said perhaps over several decades a deviation from the natural population could be prevented. Willard asked what the contemporary hatchery samples would be compared against. Truscott suggested comparing the contemporary hatchery-origin fish against the contemporary natural-origin fish and to the natural-origin baseline.

Peter Graf said in most cases the natural-origin fish would be tested anyway for the conservation programs. Truscott said any hatchery-origin fish should be tested because hatchery-origin fish are on the spawning grounds and some gene flow would occur every year. Bill Gale agreed, if hatchery-origin fish are being used for brood. Gale asked if it would be necessary to test the hatchery-origin fish in the conservation programs and safety net programs to identify divergence. Gale said the additional effort may be reasonable with newer genetic analysis techniques. Graf said that may triple the number of samples if we test natural-origin conservation program fish, hatchery-origin conservation program fish, and hatchery-origin safety-net program fish.

Hillman said the revisions could be made in the hypotheses in Section 7.1.1. of the M&E Plan. Hillman also suggested rephrasing the hypotheses in terms of bioequivalence testing. This requires the Committees to identify a biologically meaningful effect size.

Greg Mackey said Douglas PUD also talked with Seamons. Mackey said that neutral markers are used to look for genetic drift; these genes should not be related to selective traits. Mackey said that Seamons said geneticists really want to understand what the markers of selective traits are. Mackey said that especially for small hatchery programs such as the Twisp component of the Methow spring Chinook salmon population that uses a broodstock of 30 fish, the reproductive success is variable and the returns from that small population are likely to be different from the larger population, making genetic monitoring results hard to interpret. In this case, Seamons suggested monitoring only the wild population to ensure its genetic baseline is stable in time. The point is that a lot of samples could be analyzed, and the results may still not provide information that can be used to inform management decisions.

Graf said if the hatchery fish are not a separate population, there should not be divergence from the wild population because of genetic mixing within the broodstock and on the spawning grounds. He said the difference year-over-year depends on which part (e.g., subsample) of the population is taken for broodstock. Truscott said yes, that may be true if the proportion of natural-origin brood is 1 every year. Gale agreed but said the degree that the populations are mixed is different every year.

Gale asked if it would help if the hypotheses were rephrased to look for a genetic difference, then ask the geneticists to review the hypotheses again to determine what difference is meaningful. Willard suggested asking the geneticists to provide an effect size. Gale and Mackey said they interpreted that the genetics panel would indicate that it depends upon things like population size. Truscott said he would expect more deviation to occur with a small population.

Hillman said in terms of bioequivalence testing, the hypotheses statements would be reversed from the current version and refined with an effect size. Willard said it is not likely that the committees could agree to a level of biological significance in genetic divergence for making management decisions. Gale suggested establishing a threshold for re-evaluating whether there is a biologically relevant difference. Hillman said a similar situation occurred in observed differences between adult hatchery-origin and natural-origin sizes and the Committees determined the observed difference was not biologically significant.

Willard said she would ask Seamons, and Gale said he would ask Christian Smith (USFWS geneticist) for their opinions on an effect size.

Mackey said the intent of the report is to provide information that can be used by managers for making decisions. Mackey said the results need to be put into context with the significance of the results.

Hillman asked Truscott if the change [to compare genetics of contemporary hatchery-origin fish to contemporary natural-origin fish and the natural-origin fish baseline] should be made to several of the genetic analysis approaches in the M&E Plan. Truscott said yes, this would be a recommended revision.

Hillman revised a hypothesis to compare contemporary hatchery-origin fish to the natural-origin contemporary broodstock and baseline. Willard said she would take this hypothesis and discussion regarding bioequivalence back to Todd Seamons and would provide an update at the next meeting.

E. 2019 Broodstock Collection Updates

Bill Gale said Entiat National Fish Hatchery has a few summer Chinook salmon coming in and expects a bigger pulse.

Greg Mackey said Wells Fish Hatchery had collected most of the summer Chinook salmon broodstock to support production for the orca program and surplused a lot of fish for tribal consumption. Mackey said some fish were also held for transport above Grand Coulee Dam. Gale asked about the Yakima Basin summer Chinook salmon program. Mackey said the Yakama Nation (YN) has taken fish for food but have not taken adults for broodstock. Gale said he thought adults could not be transferred from the Columbia River to the Yakima Basin for fish health reasons; this is the reason the YN has historically taken eggs.

F. Broodstock Collection Topics: Discussion Plan

Tracy Hillman asked Mike Tonseth to identify the draft timeline for BCP production described in the existing SOA. Tonseth said that unlike the previous SOA that was specific to HCP programs, this version would include the PRCC HSC programs as well. Tonseth said parts of the SOA were brought into the bulleted timeline and it reflects when discussions of major topics should occur and when deliverables should be available for review to ensure that work on any major issues starts in September, well in advance of the draft BCP review. This would also be the time that individuals would be tasked with leading discussions. That is, assignments would be made in November. Discussions and agreements would be finalized in December. The draft document would be finished by January 10 for internal permit holder review. By February, the draft would be available for all committee members. The March and April dates are the standard schedule used in past years for delivery to NMFS and USFWS. Tonseth said the previous SOA only identified NMFS as the recipient; he included USFWS because of their role in permit review.

Peter Graf noted that the issues for early discussion would be related to programmatic changes that are not dependent upon run-size projections, which are rarely available until spring. Graf suggested adding placeholders to the BCPs for content that depends on run-size projections. Tonseth said it is correct that the *US v. Oregon* Technical Advisory Committee (TAC) forecast is typically available in December for fall Chinook salmon, sockeye salmon, and steelhead, and a more localized approach is being used for spring Chinook salmon because the TAC projection is not very accurate for spring Chinook salmon at the local level. Topics like marking plans and trapping locations, operations, and methods can be resolved earlier. Tonseth said this should not preclude having some discussions later in the timeline as opinions can change.

Bill Gale asked when Tonseth would like information submitted from HCP parties. Tonseth requested that information be received by mid-November and noted it could be brought forth sooner but receiving it by mid-November allows for the document to be developed in a timely manner.

Gale suggested adding language to re-valuate the timeline after the first year of implementation.

Deanne Pavlik-Kunkel said that a separate SOA may be required for the different committees. Tonseth said that’s acceptable but suggested starting with one document and replicating them later for the separate PUDs, and Pavlik-Kunkel agreed.

Graf said one consideration is that broodstock collection for fall Chinook salmon programs occurs much later in the year than other species, so discussions could occur later than for other programs. Tonseth agreed and said the content is mostly consistent from one year to the next, but the BSPs are a living document that can be modified within the year as an adaptive management tool.

Hillman projected and read through the list of topics that would require early discussions to support BCP revisions (Attachment B). Committee members were identified to lead discussions of individual topics. Gale suggested identifying items that require deliberation and decision in the Committees but are not necessary for development of the BSPs, such as conservation program sizing, source for

Chiwawa spring Chinook salmon broodstock, and out-planting Methow spring Chinook salmon spawners. Graf asked if it is possible to identify the timing for the discussions that may affect program sizing. Tonseth said for some topics, dates must remain flexible because the programs are waiting for information (e.g., to resolve program sizing based on the results of Wenatchee Basin life-cycle modeling or spring Chinook salmon pre-spawn mortality estimates) and some of that information will become available with development of the 10-year Comprehensive Report in 2020.

Hillman assigned meeting dates to topics that could be addressed for the next annual BCP and noted topics where decisions are pending additional information.

Tonseth said per the conversations on conservation program resizing that have been ongoing in the HCP-HC meetings, the first program for consideration is Nason Creek. Methow programs may be discussed later.

Kirk Truscott said for identification of natural-origin Okanogan spring Chinook salmon to distinguish them from natural-origin Methow spring Chinook during trapping at Wells Dam, the method would need to be determined for 2021. Truscott said there may be a desire to carry out some work to start establishing the baseline this year.

Greg Mackey suggested adding a line for identifying requests for adults for research or non-routine use of fish. Tonseth said needs can be identified in the BCP for programs that want to lock in their requirements, but these non-routine requests could also be considered later in the year. Requests may require a Joint Fisheries Parties (JFP) discussion first to determine whether there is an effect on HCP programs, then incorporation into the BCPs, if possible. Gale asked if the need for JFP discussion would pertain to additional requests for adults that are surplus to production. Tonseth said the JFP discussion is to determine the use of adults that are surplus to the production to meet requests prior to distribution for consumption. Tonseth said one consideration which may involve HC discussion is whether a surplus request (once surplus is identified) for a study or evaluation that benefits an HCP program would have priority before other considerations. Mackey said the intent of his suggestion was simply to make sure these requests are considered ahead of time.

Tonseth suggested sending the SOA to the HCP-HCs and PRCC HSC for review and final approval in the October 16, 2019 meeting. *(Note: Rohrbach distributed the* Broodstock Collection Protocols Development Timeline Statement of Agreement *following the meeting, requesting that edits be returned to Mike Tonseth by September 6, 2019.)*

G. National Marine Fisheries Service Consultation Update

Brett Farman said Emi (Kondo) Melton has sent the Chinook salmon and steelhead permit bundle for internal signature, and then it will be sent out for countersignature by the program managers.

Greg Mackey said he received a note that there could be a request for signatures from NMFS within two weeks.

III. Wells HC

A. Wells Hatchery Subyearling Production Expansion

Mike Tonseth said last month a discussion was initiated in which WDFW asked for concurrence from the Wells HC that the existence of a 500,000 subyearling summer Chinook salmon program reared at Wells Fish Hatchery for orca prey would not compromise the existing, on-station HCP programs. He said the discussion was initiated to demonstrate what capacity exists at Wells Fish Hatchery and what additional capacity would be needed. Tonseth sent an email on August 20, 2019, to Tracy Hillman and Larissa Rohrbach that breaks those requests out. *(Note: Tonseth's email was distributed by Rohrbach to the Wells HC following the meeting.)* The original proposal was for 1 million smolts per year to be reared at a cost of $350,000. The Washington State legislature responded to the proposal with funding for $350,000 for the biennium, allowing for only half the number of smolts, but ultimately WDFW would like to achieve the production of 1 million smolts from the Upper Columbia River. Tonseth calculated the needs for both the 500,000 and 1 million-smolt production size. His conclusion was that even with an addition of 1 million subyearlings, only about 85% of the capacity of Wells Fish Hatchery would be in use. He said the limitations pertained to the adult holding capacity rather than juvenile rearing capacity.

Hillman asked Tonseth if the conclusion was that this production would not adversely affect the Wells Fish Hatchery production. Tonseth said yes, even if this program were held in common rearing vessels, densities would be well below the management protocols of 0.06 lbs/ft^3/inch. Hillman asked if these fish would be reared separately. Tonseth said no, these would be reared in common in the same dirt ponds, allowing the program to use the coded wire tag data associated with the Wells production fish to track success of the 500,000-smolt orca prey program.

Tonseth said the additional production may result in an increase of surplus adult returns of up to 1,500 fish. Tonseth said funding will be requested for additional years but at this time there is only funding for 2 years.

Kirk Truscott asked if there is any concern about chilled water availability. Greg Mackey said there is plenty of chilled water incubation space available, beyond what is commonly used.

Tonseth requested that the Wells HC vote on the additional subyearling production via email within 10 days from today, by September 4, 2019. Truscott said CCT is prepared to vote now in the affirmative.

(Note: Bill Gale responded to the Wells HC via email on September 3, 2019, stating USFWS's vote in concurrence is based on the following understanding,

> *"Our understanding is that [brood year] BY 19 production can move forward because surplus adults are available and that there was consensus among the fishery co-managers about distribution of surplus for this portion (i.e. this productions (sic) is sourced through WDFW's share of surplus). However, production in [brood year] BY 20 will depend on 1) the designation of surplus brood being available, and 2) the distribution of that surplus in a manner that has the approval and consensus of the fishery co-managers.")*

(Note: Additional information on Wells Hatchery rearing capacity was provided by Greg Mackey, and distributed by Larissa Rohrbach, to the Wells HCP-HC on September 9, 2019, included as Attachment C to these minutes.)

IV. Rock Island/Rocky Reach HC

A. 2020 Draft Monitoring and Evaluation Implementation Plan

Catherine Willard said there were no major changes regarding activities to be implemented in 2020 compared to 2019. Willard said changes including improving wording, permit number updates, and updates to Table 1 to show who is doing what activities.

Willard said methods used to estimate brood year 2020 steelhead spawner abundance by tagging at the Off-Ladder Adult Fish Trap that had been historically done by WDFW would be carried out by Chelan PUD. Greg Mackey asked whether there would be any spawner surveys at all. Willard said they will still do spawner surveys in the lower Wenatchee River. She said Chelan PUD is looking at are other methods that could be used to estimate spawner abundance without spawning surveys in future years.

Kirk Truscott said Objective 7 for collecting genetic samples does not appear in the summary tables. Willard said she would revise the tables to add that objective. Truscott said there was a reference to methods consistent with the 2018 steelhead release plan and said that release plan should be appended to the document. Willard agreed to append the steelhead release plan.

The draft 2020 Chelan PUD M&E Implementation Plan was revised by Willard and distributed by Larissa Rohrbach on August 21, 2019, to the HCP-HCs via email for review through August 30, 2019.

V. PRCC HSC

A. Approve the July 17, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the July 17, 2019 meeting minutes as revised.

Bill Gale asked if there were any updates to the ongoing broodstock collection activities. Deanne Pavlik-Kunkel said no, everything is following the typical routine and plans. Pavlik-Kunkel said there is a new plan for surplusing fish. Gale asked if the surplussing plan has been shared with other parties. Mike Tonseth said it has not been shared outside of the requestors for surplus. Pavlik-Kunkel said it had not been shared more broadly because it was about logistics, schedule, and where and when surplus fish would be distributed.

B. Wenatchee Spring Chinook Salmon Life-Cycle Model: Data and Questions

Tracy Hillman projected a draft list of questions for Jeff Jorgensen in preparation for Jorgensen's presentation in the September 25, 2019 PRCC meeting. Hillman added to and revised the questions during the discussion.

Bill Gale asked if the focus would be on modeling the effect of re-implementation rather than the effect of the previous program implementation. Peter Graf responded that the intent was to identify questions that would prepare Jorgensen for the discussion in the next PRCC meeting such as how well the model reflects reality based on modeling of the Nason and Chiwawa rivers and how the model could be applied to the question of restarting a hatchery program.

Gale asked what Jorgensen has been asked to talk about specifically. Hillman said the model was designed to evaluate the effects of different factors, including hatchery programs, on the survival of the Wenatchee spring Chinook salmon population.

Kirk Truscott reiterated the question of what data would be required to develop a model for a White River component of the spring Chinook salmon population in general; for instance, what level of predation occurs in the lake, where in the lake does it occur, what are the major predators, etc. Truscott said there is a decision pending in 2026 whether to implement the program or not. Truscott said he does not believe it is acceptable to walk away from implementing a White River hatchery program if NMFS advocates that the program is important for recovery of the Wenatchee population. Truscott said there could be other management actions, such as predator reduction, as an alternative to hatchery production.

Graf said the difficulty in moving the issue forward in the PRCC and the PRCC HSC has been determining what the targets for mitigation should be. Graf said, of course, any information on factors like predation would benefit the model but pursuing that information may not help lead to a decision related to hatchery mitigation.

Gale said he supports implementing the model, but to answer the question of whether to start a hatchery, as a collective group, the PRCC HSC would want to be in the position of determining what Grant PUD's mitigation obligations are. A perfect model of the life cycle is not the only solution to answering those hard questions. Graf agreed and said the model will inform all the programs, but it won't answer the main questions of whether to construct a hatchery in the White River, what the broodstock would be, whether to composite the broodstock, etc.

Truscott said if you could quantify predation by bull trout, for example, the likelihood of reducing or eliminating bull trout predation is low, and the model will inform you that no matter how many fish are produced in a hatchery, survival would be low. Graf said that a model of the White River may not necessarily be needed to inform the outcome of a potential hatchery program because information on Nason and Chiwawa survival exists, and Lake Wenatchee survival estimates exist.

Hillman said Jorgensen's life-cycle model isn't built to estimate predation in the lake. To do so, it would need estimates of predator abundance, prey abundance, consumption rates, digestion rates, temperatures, etc. Graf said the model downstream of Lake Wenatchee is the same for the Nason and Chiwawa populations. Truscott said that further work to characterize predation was proposed but not approved by consensus in the PRCC. Truscott said if the predator is pikeminnow, for instance, the problem could be managed and a hatchery program may be viable. Gale said it is more complex than that. For example, bull trout may increase predation on smolts if the number of competing pikeminnow is reduced. Gale said his view is that the White River population may be unique because it has co-evolved with other species in Lake Wenatchee. Gale said he would hesitate to recommend knocking down predator abundance in this ecosystem. Graf said identifying the source of predation in the lake is a food-web study, which would be a different study than a survival study to support Jorgensen's model. Truscott said his concern is arriving at 2026 without data supporting a decision on how to recover the White River spawning aggregate.

Gale said he would like to hear more about why the White River spawning aggregate is so important to the recovery of the species. Graf said a status review will occur soon that may inform that question. Truscott said diversity is one reason. Hillman said the importance of White River spring Chinook salmon goes back to the Quantitative Analysis Report and the development of the HCPs. At that time, the National Oceanic and Atmospheric Administration (NOAA) and others struggled with determining the importance of the White River group. Because of its genetic divergence from the Wenatchee population, some thought it should be identified as an independent population (separate from the Wenatchee population). It was decided, however, that White River spring Chinook salmon should be designated as an important aggregate of the Wenatchee population. In the recovery plan, White River spring Chinook salmon were designated as a separate spawning aggregate, which is needed to maintain diversity and allow local adaptation. Recently, Craig Busack has said they (NOAA) need to evaluate the importance of White River spring Chinook salmon for recovery. Truscott said White River natural-origin spawners are still the most divergent of all the spawning aggregates in the basin. If there was no survival benefit of having White River genes, wouldn't they have the same genetic profile as the Chiwawa fish? Chiwawa fish have been spawning in the White River as long as the program has existed and for some reason they are not as successful as the White River fish. There's still enough genetic differentiation that they can be identified during broodstock collection to differentiate from Chiwawa and Nason fish. Gale said he'd like to know if the genetic differentiation has already been lost due to over-escapement of Chiwawa fish into the Nason and White rivers and he would like to see a comparison using modern genetic analyses to past analyses. Graf said genetics work to be completed in 2019 and 2020 will answer some of those questions. Gale asked if White River fish will be sampled on the spawning grounds. Graf said yes, carcasses in the White River will be sampled. Hillman said there have been about 25 years of genetic influence of the Chiwawa program on the White River aggregate.

Hillman said Jorgensen's model evaluates the effects of hatchery production on survival using proportion of hatchery origin spawners (pHOS) in the Wenatchee Basin. Graf said the model worked by discounting the spawning success of that natural population based on the influence of hatchery fish. Truscott recalled that Jorgensen was adamant that food-web information in the lake would be necessary to model the population survival. Graf agreed if you want that level of information. However, if you want a simple survival number, it's not necessary.

Gale said the best thing managers could do would be to prevent Chiwawa fish from over-escaping into the White River. Truscott said changes have been made in that direction by carrying out adult management at Tumwater Dam and reducing jack rates because jacks stray more than older fish.

Hillman asked Brett Farman if he had any questions for Jorgensen. Farman said that he did not. Tom Scribner said he would like to ask NOAA (Busack) how important the White River is to recovery, if in fact modeling shows that the impacts in Lake Wenatchee are insurmountable for sustaining a hatchery population. Hillman suggested Busack participate in the September PRCC meeting so he can address some of those questions. Farman said he will invite Busack.

Graf said Grant PUD would send more questions to Hillman for Jorgensen before the end of the month. Hillman requested that members provide any additional questions for Jorgensen by August 30, 2019. Hillman will then forward questions to Jorgensen.

VI. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are September 18, 2019, October 16, 2019, and November 20, 2019, at Grant PUD in Wenatchee, Washington.

Attachment B
Broodstock Collection Protocols Discussion Topics for 2020

Topic	Discussion Lead	Meeting Date for Discussion
Review of the Broodstock Collection Protocols to identify major revisions needed and assign co-authors	Tracy Hillman	September
Elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs	Kirk Truscott	
Sizing of upper Columbia River conservation programs**	All	TBD—Based on prespawn survival (currently working on Nason Spring Ch)
Use of age-3 males in broodstock Use of alternative mating strategies	Greg Mackey	Sept
Establishing ranges around broodstock collection targets	Greg	Sept-Oct
Source for Chiwawa spring Chinook salmon broodstock	Catherine	Oct
Outplanting surplus Methow Composite Spring Chinook Salmon Adults**	Mike	Sept-Oct
Request for HCP surplus adults for research or other requests	All	Sept-Feb
Revised Broodstock Collection Protocols Development Timeline SOA	Mike Tonseth	

**Programs in part independent of BSP.

Attachment C
Information for the Wells Orca Production Discussion and Vote Request

Wells Hatchery Capacity
September 9, 2019

The following provides information on incubation and rearing space allocation and chilled water supply. This demonstrates that Wells Hatchery has sufficient capacity to incubate and rear the Orca summer chinook program in addition to programs already in production. The Dirt Pond 3 "sink hole" that developed in 2017 was likely caused by a leak in the old liner at a location where an old buried (previously unknown) concrete structure existed. We believe, after excavating this area, that the concrete structure exacerbated the erosion. Dirt Pond 1 has been relined and is currently in service. By September 26, 2019 Dirt Ponds 3 and 4 will be lined with a new heavy duty Coletanche liner. Dirt Pond 2 is not currently in active use but is still operational if needed. All other incubation and rearing facilities are 100% operational.

1. Trout:
    a. Incubation in old building September – March. Shallow Troughs. No chilling required.
    b. Early Rearing in old building.
    c. Grow Out: Bureau Ponds, Above Ground Ponds, Dirt Pond 3B. Final Grow Out in Dirt Pond 3B.
2. Sturgeon:
    a. Early rearing in Sturgeon Room circulars. No chilling.
    b. Grow Out in Sturgeon Room circulars.
3. Summer Chinook Yearlings:
    a. Incubation in one large Incubation Room. Chilled for ~240 days to slow down growth (October – May).
    b. Early Rearing in Production Room spring.
    c. Transitional rearing in Above Ground Ponds or Bureau Ponds
    d. Grow Out in Dirt Pond 1 September – April.
4. Summer Chinook Subyearlings:
    a. Incubation in one large Incubation Room. Chilled briefly to synch up egg take dates (October-November).
    b. Early Rearing in Production Room late winter.
    c. Transitional rearing in Above Ground Ponds or Bureau Ponds
    d. Final Grow Out in Dirt Pond 1 April - May.
5. Steelhead Columbia Safety New and Methow Safety Net:
    a. Incubation in one small incubation room April-June. Chilling as needed to synch up egg take dates.
    b. Early Rearing in Production Room in summer.
    c. Transitional rearing in Circular Ponds
    d. Final Grow Out in Dirt Ponds 4A and 4B.
6. Okanogan Steelhead:
    a. Incubation in one small incubation room April-June. Chilling as needed to synch up egg take dates.
    b. Early Rearing in Production Room in summer.
    c. Transitional rearing in Circular Ponds
    d. Final Grow Out in Circular Ponds.

Attachment C
Information for the Wells Orca Production Discussion and Vote Request

7. Twisp/Methow Conservation Steelhead:
    a. Early incubation at WNFH – eyed eggs to Wells Hatchery in summer – one small room.
    b. Early Rearing in Production Room in summer.
    c. Rearing in Circular Ponds
    d. Final Grow Out in Circular Ponds.
8. Coho:
    a. Early incubation at WNFH – eyed eggs to Wells Hatchery in December – one small room. Chilling December – April.
    b. Early Rearing in Production Room in summer.
    c. Transitional rearing in Circular Ponds
    d. Final Grow Out in Dirt Pond 3A.
9. Summer Chinook Subyearlings Orca Program:
    a. Incubation in one large Incubation Room with HCP Subyearlings. Chilled briefly to synch up egg take dates (October-November).
    b. Early Rearing in Production Room late winter.
    c. Transitional rearing in Above Ground Ponds or Bureau Ponds
    d. Final Grow Out in Dirt Pond 1 April - May.

Incubation: Wells Hatchery has 7 new incubation rooms. Chilling capacity is 250 gpm to 38 F from a pair of new Daiken chillers. Wells Hatchery also has an additional incubation facility in the old building with 672 trays and a separate chiller that supplies 40 gpm of 38 F water (This is the chiller that was sufficient to produce the entire Wells Hatchery Summer Chinook production prior to the modernization project. We service and operate this chiller annually to keep it in full operational condition). The maximum incubation chiller demand is 190 gpm when Subyearling Chinook (HCP and Orca), Yearling Chinook, and Coho all use chilled water (Subyearlings and Coho may not overlap), resulting in at least 60 gpm of surplus chilled water capacity in the new building and 40 gpm in the old building summing to 100 gpm total. Regarding the 7 incubation rooms in the new building: During the October – May incubation period all summer Chinook production may use up to the 2 large rooms, Coho 1 small room, steelhead 2 small rooms (in spring). There will be at least 2, and normally 4 empty rooms at any one time. Thus, there is plenty of capacity to meet incubation needs.

Rearing : Dirt Ponds 3, and 4 are in the process of being re-lined and will be complete by September 26, 2019. Dirt Pond 1 is already complete and is in use. Dirt Ponds 3 and 4 have each been split into two sections (3A, 3B, 4A, 4B) with separate release structures for each. The ponds are being re-lined with a heavy duty Coletanche liner. Dirt Pond 2 is not required for production but is available and supplies a massive amount of rearing space. Rearing in all of the Dirt Ponds is at very low fish densities.

All other rearing vessels (Bureau Ponds, Above Ground Ponds, Adult Ponds, Circular Tanks, Production Room, old Production Room, Sturgeon Room) are in 100% operational capacity.

Contingency Plan: As illustrated above, Wells Hatchery has sufficient and redundant capacity to meet the fish rearing needs. Should a portion of the facility become unusable, the unused capacity of the facility will be used to compensate. The new Hatchery Building has extra incubation space if needed. Production Room space typically is open expect for fairly short periods when Chinook are present, and we added 4 new large start tanks in 2019 to increase capacity and flexibility. Another 4

Attachment C
Information for the Wells Orca Production Discussion and Vote Request

will be installed in 2020. The old Hatchery Building has enough incubation and early production space to compensate for an event in the new building. The facility has multiple rearing options, and fish can be moved around as needed. For large groups fish can be moved to Dirt Pond 2. Dirt pond 2 has been surveyed using geologic electro-resistivity techniques and no voids were detected. In the case of a loss of water supply due to an electrical or pump outage, we have a detailed Emergency Action Plan for hatchery staff to follow to quickly restore the water supply, and contingency actions to take with aerators and oxygen, as needed.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: October 16, 2019

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the September 18, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, September 18, 2019, from 9:00 a.m. to 2:30 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is going.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*
- Brett Farman will discuss with Charlene Hurst (NMFS) and Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will distribute a white paper reviewing broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A). *(Note: this item is ongoing.)*
- Larissa Rohrbach will add HCP Policy Committee guidance on policy-level issues to the HCP-HC Meeting Protocols (version dated May 15, 2019; Item I-A).
- Tonseth will distribute a suggested drafting plan for the Broodstock Collection Protocols (BCPs) assigning specific members to address topics for discussion; Tracy Hillman will determine

whether there is a need for an additional conference call in early October to discuss research needs to address given topics (Item II-B).
- Catherine Willard will coordinate with other HCP-HC and PRCC HSC members to draft separate sets of genetic monitoring hypotheses that are specific for the individual hatchery programs to monitor for changes in population genetics over time (Item II-C).

PRCC Hatchery Subcommittee

- PRCC HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item I-A). *(Note: This item is ongoing.)*
- Brett Farman will ask Craig Busack (National Marine Fisheries Service [NMFS]) to participate in PRCC HSC process for identifying data needs and making a decision on the White River spring Chinook salmon hatchery program (Item I-A).

Decision Summary

- The Wells HCP-HC voted to concur that there is sufficient capacity at Wells Fish Hatchery for WDFW's additional production of subyearling Chinook salmon for southern resident orca prey, without compromising the existing, on-station HCP programs, confirmed via an email by Larissa Rohrbach on September 11, 2019 (Item I-A).
- The Rock Island and Rocky Reach HCP-HCs voted to approve the *Relative Reproductive Success Study Extension SOA Memorandum* in today's meeting (Item II-A).
- The HCP-HCs and PRCC HSC voted to approve the *Broodstock Collection Protocols Development Timeline Statement of Agreement* in today's meeting (Item II-B).
- The Wells HCP-HC voted to approve Douglas PUD's 2019 Egg Treatment Study Plan in today's meeting (Item III-A).
- The Rock Island and Rocky Reach HCP-HCs voted to approve Chelan PUD's 2020 Draft Monitoring and Evaluation Implementation Plan in today's meeting (Item IV-A).

Agreements

- The HCP-HCs and PRCC HSC agreed to describe the alternative method of equivalence testing in the narrative in the genetic monitoring objectives of the PUDs' Monitoring and Evaluation Plan (M&E Plan).

Review Items

- Larissa Rohrbach sent an email to the Wells HCP-HC on September 16, 2019, notifying them that Douglas PUD's draft 2018 Monitoring and Evaluation Report for the Wells and Methow programs is available for 60-day review with edits due by Friday November 15, 2019 (Item I-A).

- Rohrbach sent an email to the Wells HCP-HC on September 20, 2019, requesting a vote by email to indicate agreement with Douglas PUD that releasing surplus fish from the Methow Safety-Net and Columbia Safety-Net Programs into a non-anadromous lake will not prevent the HCP steelhead programs from meeting the target production.

Finalized Documents

- The Monitoring and Evaluation of the Chelan and Grant County PUDs Hatchery Programs 2018 Annual Report was distributed via email by Larissa Rohrbach on September 16, 2019.
- The Rock Island and Rocky Reach HCP-HCs-approved *Relative Reproductive Success Study Extension SOA Memorandum* was distributed via email by Rohrbach on September 23, 2019 (Item II-A).
- The Rock Island and Rocky Reach HCP-HCs-approved *Broodstock Collection Protocols Development Timeline Statement of Agreement* was distributed via email by Rohrbach on September 23, 2019 (Item II-B).
- The Wells HCP-HC-approved *Broodstock Collection Protocols Development Timeline Statement of Agreement* was distributed via email by Rohrbach on September 23, 2019 (Item II-B).
- The Wells HCP-HC-approved *2019 Egg Treatment Study Plan* was distributed via email by Rohrbach on September 23, 2019 (Item III-A).

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the August 21, 2019 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC and reviewed safety procedures on safe egress and first aid, should an emergency occur during the meeting.

Hillman asked for any additions or changes to the revised agenda (distributed via email by Larissa Rohrbach on September 17, 2019). The HCP-HCs and PRCC HSC members voted to approve the revised agenda.

The HCP-HCs and PRCC HSC representatives reviewed the revised meeting minutes. Rohrbach said there were some revisions that the representatives then reviewed. Additional revisions were made in the meeting. The HCP-HCs and PRCC HSC members approved the meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on August 21, 2019, were reviewed, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on August 21, 2019)*:

Joint HCP-HCs and PRCC HSC

- Mike Tonseth will coordinate with Andrew Murdoch (WDFW) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A).
  Tonseth said this item is ongoing. Tonseth said pre-spawn mortality has been estimated for females but not yet for males. Todd Pearsons asked if this topic is going to be discussed by Jeff Jorgensen in the September 25, 2019 PRCC meeting. Keely Murdoch said Jorgensen gave a presentation to the Regional Technical Team (RTT) last week that will probably be similar to what will be presented to the PRCC. Tracy *Hillman said that in the RTT meeting, Jorgensen did note that model results were sensitive to pre-spawn mortality. Murdoch said Jorgensen compared the Wenatchee populations with others, particularly Willamette River spring Chinook, and he said the pre-spawn mortality observed in the Wenatchee River is not atypical compared to other basins. Pearsons asked if pre-spawn mortality estimates are needed for the long-term need to discuss changes to conservation program sizing. Murdoch said yes, pre-spawn mortality is needed for the crude back-casting she has done to work on conservation program sizing. It was suggested that the life-cycle model could be used to inform a new model to forecast sizing of the conservation programs. Murdoch said she believed that early estimates of pre-spawn mortality included in program-size back-casting are too low; the data that were used were from the original Wenatchee spring Chinook management plan that was written early in the process of collecting pre-spawn mortality data. Tonseth said he did not know if pre-spawn mortality information would be passed to Jorgensen for inclusion in the Wenatchee life-cycle model.*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A).
  Truscott said this item is ongoing.
- Brett Farman will discuss with Charlene Hurst and Tonseth the potential use of a multi-population model for estimating PNI for the Nason and Chiwawa spring Chinook salmon programs (Item I-A).
  Farman said this item is ongoing.
- Hillman and Larissa Rohrbach will add review of the BCPs to the September meeting agenda to help the HCP-HCs and PRCC HSC identify co-authors and opportunities to discuss major revisions in advance of 2020 deadlines (Item II-F). *This item will be discussed in today's meeting. This item is complete.*
- Greg Mackey will distribute a white paper reviewing broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A).

Mackey said this item is ongoing. Mackey said the paper is complete and will be distributed after the meeting. He will give a presentation on this topic in today's meeting.

- Rohrbach will add HCP Policy Committee guidance on policy-level issues to the HCP-HC Meeting Protocols (version dated May 15, 2019; Item I-A).
  Hillman said this item is ongoing, pending finalization of the HCP Policy Committee meeting minutes. He said the draft meeting minutes were distributed a few days ago asking for a couple of weeks for meeting attendees to review.
- Catherine Willard will update the genetics section of the *Monitoring and Evaluation Plan for PUD Hatchery Programs (Update to the 2017 Plan)* to reflect revisions that were suggested in the August 21, 2019 meeting (Item II-D).
  Willard sent an updated version to the HCP-HCs and PRCC HSC as distributed by Rohrbach on September 17, 2019. This topic will be discussed in today's meeting. This item is complete.

PRCC Hatchery Subcommittee

- HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item I-A).
  Hillman said this item is ongoing.
- Brett Farman will ask Craig Busack (NMFS) to participate in the Wenatchee Basin life-cycle modeling discussion at the PRCC meeting on September 25, 2019, at Wanapum Dam, Washington (Item V-B).
  Farman said neither he nor Busack will be able to participate in the September 25, 2019 PRCC meeting due to an internal conflicting meeting. Hillman asked if Busack will be able to re-engage with the HSC. Farman said he will discuss this with Busack on Friday. This item is complete.

II. Joint HCP-HCs and PRCC HSC

A. DECISION: Relative Reproductive Success Study Extension SOA Memorandum Update

Mike Tonseth said Catherine Willard provided suggested edits to the section on ESA Take and Permitting via email between meetings. Tonseth said Willard's changes were incorporated for clarity but no substantive changes were made to the plan from the previous version.

Todd Pearsons said it seems like there was concern about the adult sampling rate at Tumwater Dam and how that sampling rate may affect the PUD programs. Pearsons said for example the Relative Reproductive Success (RRS) Study Plan is written for a 100% sample rate of returning natural-origin adults, and the PUDs don't need a 100% sample rate and may only need to sample 3 to 4 days per week, which could be a source of conflict. Tonseth said the permit allows a 100% sample rate.

Tonseth said he does not see the connection to the PUD programs. Pearsons asked whether this SOA summarizes what is ongoing in the RRS Study. Pearsons said he thought the sampling rate was intended to collect a representative subsample versus a 100% sample, at least during the main portion of the adult spring Chinook sample run.

Tonseth said the goal of the study has always been to sample up to 100% of the natural-origin adults based on the assumption that a larger sample size would provide better data. Tonseth said they recognize that sampling all adults is not always possible. For instance, achieving an 80% sample rate is acceptable. Tonseth said the focus of the RRS Study extension memorandum is natural-origin adults; the hatchery-origin adults are not part of this memorandum.

Pearsons asked whether it is necessary to have 80% to 100% of the offspring of the RRS Study fish genetically typed back to the parents. Pearsons said he thought this would be analogous to sampling the smolts at the smolt trap; to capture a subsample of the total population. Tonseth said it is correct that the intent is to collect an adequate number of genetic samples from the progeny of the parents who are the focus of the RRS Study analysis. Tonseth said the smolt trap is only capable of sampling a portion of the river and smolts at one time, whereas at Tumwater Dam they have the ability to sample nearly all fish.

To clarify, Willard asked whether the original RRS study plan did state the goal was to sample 100% and the reason for this revised SOA was to extend the duration of the study? Tonseth said yes, and to ensure the focus of the study was on natural-origin adults.

Hillman asked Pearsons whether his question was to clarify management goals or to determine potential effects of RRS Study sampling on PUD programs? Pearsons said clarity should be provided in the SOA revisions that the goal is to sample 80% to 100% or a representative sample of the natural-origin returns. Pearsons said when a study requires 100% sampling or a relative subsample, it has been communicated in committee in the past.

Hillman suggested adding a sentence to the Proposed Action stating the permit allows for sampling up to 100% of adults. Pearsons suggested adding a sentence about the intent, not just what is allowed. Tonseth said the intent is to sample 100% of the population, if possible. Bill Gale suggested adding a sentence that reads, for example, "the goal of the study is to sample the maximum amount of the natural-origin population as possible, up to 100% of adult fish passing over Tumwater Dam."

Hillman called for a vote of the Rock Island and Rocky Reach HCP-HCs and PRCC HSC to approve the revised *RSS Extension SOA Memorandum*, including the revisions suggested in today's meeting. All members of the Rock Island and Rocky Reach HCP-HCs and PRCC HSC voted to approve the memorandum.

Tonseth said he will finalize the *RRS* Study *Extension SOA Memorandum* by including today's revisions and distribute it to the HCP-HCs and PRCC HSC (Attachment B).

B. DECISION: Broodstock Collection Protocols Development

Broodstock Collection Protocols Timeline SOA

Mike Tonseth said there are no major revisions to the Annual BCP timeline SOA compared to the version distributed last month.

Bill Gale suggested adding some language that the committees will re-evaluate the effectiveness of the new timeline on a given date and determine if changes are necessary. Tonseth said he did not include specific dates in this SOA because he was trying to avoid having to develop multiple SOAs over several years. Greg Mackey asked Gale what direction he thinks the schedule could shift? Gale said given how complicated developing the BCPs has become over the past years, he is suggesting adding flexibility in the future and a point for deciding that changes to a given topic may not be made in time for that year's BCP. Gale and Mackey agreed one check-in date should be stated in the SOA and the BSP schedule would be evaluated on an as needed basis only, after the first year.. Tracy Hillman added language to the draft SOA in the meeting to allow for the schedule to be re-evaluated in August 2020.

Tonseth said there is a need to develop several versions of this SOA for each of the HCP-HCs and the PRCC HSC. Hillman will send the revisions made to the BSP timeline SOA in today's meeting to Tonseth. Tonseth will then develop three SOAs, one for each committee (Attachment C).

The HCP-HCs and PRCC HSC voted to approve the generic version with the knowledge that it will be used as a template for developing three separate SOAs for the different committees.

Tasks and Co-Authors

Tracy Hillman asked for a review of the BCP drafting plan to assign people to lead discussions and to draft revisions on specific topics. Mike Tonseth said he will distribute a suggested BCP topics assignment list next week for all to consider. Bill Gale asked if a conference call should be scheduled to review the list between meetings. Todd Pearsons suggested discussing the list in the October meeting. Hillman said he will determine whether there is a need for an additional conference call after Tonseth sends the draft list.

Greg Mackey said he is prepared to give a presentation on establishing ranges around broodstock collection targets in October.

Gale said Michael Humling (USFWS) is available to help Tonseth develop the content on out-planting surplus Methow spring Chinook. Mackey said Douglas PUD would be happy to help with that topic.

Catherine Willard said she is waiting for data to be able to discuss the sources for Chiwawa spring Chinook topic. Discussion of this topic will be moved to the November meeting.

Hillman said Kirk Truscott's task on elemental signature analysis to differentiate Okanogan spring Chinook from other stocks is not relevant to this year's BCP but progress should be made this year to prepare for collecting samples in subsequent years.

Keely Murdoch said the Yakama Nation typically provides the Coho broodstock collection plan as an appendix.

C. Genetics Updates to the Monitoring and Evaluation Plan for PUD Hatchery Programs

Catherine Willard said two additions were made to the PUDs' Monitoring and Evaluation Plan (M&E Plan) based on feedback from geneticists and discussions in last month's meeting. [1) adding hypotheses for tests of equivalence and 2) analyzing hatchery-origin fish in addition to natural-origin fish.]

Equivalence Testing

Catherine Willard said hypotheses were added based on an equivalence testing approach. These hypotheses are in addition to the standard null-hypothesis testing approaches. Equivalence testing was recommended by the Independent Scientific Advisory Board and the writers of the original M&E Plan. Changes were made to the M&E Plan by Willard and Tracy Hillman.

Willard said she discussed the M&E updates with Todd Seamons, WDFW geneticist, and Christian Smith, USFWS geneticist, to receive the geneticists' perspective on determining important effect sizes. Willard read from an email response provided by Seamons. Seamons wrote that to his knowledge there is no existing deterministic biological meaning for effect sizes for these genetic metrics; there is solid evidence for increasing genetic diversity but no evidence for determining the importance of the size of the difference between stocks or populations. Seamons wrote that knowledge of genomes is insufficient to determine the importance of the genetic differences.
Bill Gale said Christian Smith's response was very similar. Hillman said the topic of how much genetic difference between hatchery and natural-origin fish is significant in terms of the recovery of the stocks has been discussed for many years. Gale said, simplistically, the M&E Plan will have to determine a value for deciding what is significant. Hillman said at this time, the M&E Plan allows simple statistics to determine if there is a difference between hatchery and natural-origin fish, noting that statistical significance may have nothing to do with biological or management importance. He indicated the Committees should try to determine a difference that is biologically important. Hillman said, however, it is difficult for managers to make a decision on effect size if geneticists can't decide what is a significant genetic difference.

Greg Mackey said when geneticists make a phylogenetic tree, they use a clustering algorithm. The main clustering algorithm is a bootstrap support tool to estimate the of the phylogenetic groups in the tree and also the [genetic] distance between clusters, which gives information on the confidence of how far apart different groups are [similar to effect size and statistical support]. Mackey said the post-hoc interpretation of these results is analogous to what managers have to use to identify what difference is important to the fish and program goals.

Kirk Truscott said re-occurring assessments should show the trend in assessments to look for greater and greater divergence over time. Truscott said managers also need to know the effective population size for interpretation, to decide whether effects are from hatchery influence, or are natural.

Hillman asked if a departure from the genetic baseline is observed, whether that is really a bad thing. He said it is possible that the baseline is not the ideal state because of past hatchery effects on the population. Hillman said the equivalence-test hypotheses were included in the M&E Plan for use in the future, when we have information on biological significance.

Mackey said for some metrics, we know what is a good or bad direction, e.g., it is always negative for a population when effective population size goes down. Mackey said causes for linkage disequilibrium or allele frequency shifts may be variable and not necessarily a negative impact of the hatchery population. Todd Pearsons said losing alleles is a bad thing generally. Mackey said, yes, generally an overall loss of allelic diversity would be bad, but if some alleles are lost and some are gained over time, it's hard to say whether it's bad for the program or not. Gale asked if low allelic diversity is necessarily a bad thing? Hillman said no, in his recollection of discussions with geneticists during the writing of the recovery plans, some loss of alleles happens when a population becomes locally adapted. Gale said perhaps at the scale of evolutionarily significant unit (ESU), there should be greater allelic diversity but at the local population scale, specialization would be better.

Tom Kahler asked if there is a different metric that should be used [besides allelic diversity]. Truscott said the ultimate goal is to evaluate whether the hatchery program is having a good or bad effect on the natural population. Truscott said the Committees should consider multiple aspects of a program (e.g., genetics, stray rate, productivity) to answer this question. Mackey said analyses should look for evidence for retention of genetic diversity, but also for evidence of homogenization across subpopulations from genes introduced by another subpopulation. Pearsons said there has now been a lot of review [of genetic monitoring objectives in the M&E Plan] and still there is a lot of uncertainty around the utility of the sampling and data. Pearsons agrees that it's hard to interpret the genetics data by itself, for instance (an extreme example), a population may have a very high proportion of hatchery origin spawners (pHOS) present on spawning grounds, but if the fish are not effective spawners there may be no genetic impact. You would not know this unless you looked at all the data together. Willard said once this document is updated, it can be reviewed in the future to add new metrics. Pearsons suggested adding some details to note whether it's possible to establish a prescriptive effect size. Hillman said the standard statistical effect sizes can be included, but they may not be biologically relevant; he suggested including these but adding information that the biological relevance should be reviewed in the future. Pearsons said he is fine with editing the document either way. Willard noted that in Seamons' email, he said he would not be comfortable prescribing an effect size unless it was in a publication and peer reviewed.

All agreed decisions would not be made based on one metric. Hillman said the M&E Plan was written with this in mind. Pearsons said the problem may be that the HCP-HC and PRCC HSC programs are pushing the envelope on using data from long-term genetic monitoring.

Hillman said the monitoring questions are written such that we need to demonstrate no difference between hatchery and natural-origin fish. Equivalence testing is set up to evaluate these kinds of questions. Currently, however, the hypotheses are written to demonstrate differences. We can never prove the null hypotheses to be true. Therefore, we added additional hypotheses that allow equivalence testing even though we have not yet identified important biological differences.

Hillman asked if the Committees want to retain the edits, keeping in mind the plan will change after the completion of the Comprehensive Report and the Before-After-Control-Impact analyses. Pearsons asked if we could resolve the equivalency testing issue with a note stating there is no pre-determined effect size or take these equivalency hypotheses out completely. Hillman said the original M&E Plan included this language and we can add it back into the M&E Plan.

Gale said he sees value in leaving the equivalency hypotheses in the report, using the standard statistical approaches for testing but noting that it is unknown whether statistical differences are biologically meaningful. Gale said doing the analysis may provide information that could be used in the future. Hillman said standard thresholds identified in statistical text books could be used; for instance, the probability of a small difference could be 5%, a medium difference could be 10%, and a large difference could be 20%. Pearsons suggested performing a power analysis, given the data and the amount of variability, to identify the percent difference that can be detected without using predetermined thresholds of importance. Mackey agreed and said that a power analysis answers whether the test is able to detect a difference that could be large enough to be biologically meaningful (e.g., 10%).

All Members agreed to leave the alternative method of equivalence testing in the genetic monitoring objectives of the M&E Plan. Mackey said he would like the explanation [of effect size] in the main body of the text instead of just a footnote. Hillman said he would add text in the introductory sections pointing the reader to the nature of the interpretation.

Hillman said adding hypotheses to support equivalency tests makes sense for several other objectives of the M&E Plan that do not have specific targets (in addition to the genetic monitoring objectives). Pearsons said this may be a larger process for generating biologically significant effect sizes for other metrics and he needs more time to think about including effect size for all the objectives in the entire M&E Plan. Hillman suggested writing the hypotheses generically, since an equivalence test would not be appropriate for all metrics. Hillman said this was done originally but was later eliminated. Pearsons said general hypotheses make the decision-making of biological significance more difficult because more interpretation is needed. Pearsons said relevant effects sizes for objectives could also be informed by the comprehensive report after the end of next year.

Inclusion of Hatchery-Origin Fish in Genetic Monitoring

Tracy Hillman said the second question is about allelic frequency and whether it is appropriate to test hatchery-origin fish in addition to natural-origin fish. Todd Pearsons presented slides prepared by Grant PUD to expand on the discussion (Attachment D).

Slide 2: Pearsons said the focus is on integrated programs with a conservation component and a safety-net component. Integrated programs attempt to facilitate gene flow between natural-origin and hatchery-origin fish. Safety-net programs are one-generation removed from conservation programs and [ideally] don't spawn in nature; safety-net program fish are kept separate from the conservation program fish unless a population bottleneck occurs. Pearsons said this is because programs are willing to take more genetic risk if population abundance falls below a certain level. It's highly unlikely that there are any true wild fish over time.

Slide 3: A diagram shows the likelihood of having completely wild fish by descent (i.e., no hatchery ancestry) over seven generations of conducting an integrated hatchery program. The diagram showed Wild, Hatchery, and Safety-net fish. Safety-net fish are a "dead end" and not used in the integrated program typically. The Chiwawa spring Chinook program is on approximately the fifth generation. The intent of the figure is to show that when there is a high degree of mixing between natural-origin and hatchery-origin fish, it is difficult to discern genetic differences between the two groups. Pearsons said recent events [low natural-origin returns requiring the use of safety-net fish in broodstock] suggest the use of the safety-net fish may be different in the future. Keely Murdoch said this figure doesn't show what proportion of the natural-origin fish are going into the hatchery broodstock, which in some years is a lot lower than targets. Pearsons said yes, the diagram assumes equal reproductive success of hatchery and wild fish. Kirk Truscott said this also assumes the hatchery-origin and natural-origin fish occupy the same habitat and we know that's not true. Truscott said the level of mixing can be variable. For instance, a high proportion of hatchery-origin fish spawn next to the hatchery or acclimation facility. Murdoch asked if a different approach would be taken for integrated and segregated programs. Pearsons said yes, the sampling could be different for integrated and segregated programs.

Greg Mackey said that in programs using all wild fish in broodstock, there is no hatchery lineage to test in that population. Mackey said the genetic samples would come from wild fish that could be the offspring of hatchery fish, except they would be influenced by only one generation of hatchery effects; there's no long-term hatchery lineage. Pearsons agreed and said that is at the heart of the discussion. If you were to compare hatchery and natural-origin fish, you are only comparing the effect of one generation, not six or seven generations of hatchery rearing. Tom Kahler said when it comes time to sample, one would ask "what are the hatchery fish?"

Slide 4: Pearsons said natural-origin fish are a good integrator of previous spawnings between hatchery- and natural-origin fish and reproductive success resulting from processes in nature. Pearsons said, for instance, in the Chiwawa many of those fish are not passing on genes to the next generation due to environmental conditions. He said integration of datasets on productivity with genetic analysis would inform decisions about the health of the natural-origin population. The Independent Scientific Advisory Board identified that the hypotheses were not necessarily structured to focus on the natural-origin population and so were inconsistent with the goal stated in the text.

Slide 5: Pearsons said programs are actively trying to minimize genetic differences between natural-origin and hatchery-origin fish (see Slide 5 of Attachment B for specific methods). Pearsons said early identification of divergence between hatchery-origin and natural-origin fish is addressed by monitoring PNI, stray rates, and other phenotypic measures. He asked, even if differences were detected, would it matter if it wasn't reflected in the population at large? For example, one may detect a genetic difference between hatchery-origin and natural-origin fish that are one generation removed, but all other metrics indicate the population is healthy and the natural-origin population sample does not indicate a problem. Truscott agreed these are good questions. The original perspective on genetic analysis of hatchery-origin fish was on how to sample, which analyses maximize the ability to assess a change caused by hatchery effects on the natural population, and to provide management options though we don't know what those management options would be. Truscott said a difference in genetics of hatchery and natural-origin fish may be an early indicator of a potential issue later. If the samples are not collected until decades later, the opportunity to make management changes [to limit or prevent adverse effects on natural-origin fish] may be lost. Truscott said the effort needed to collect additional hatchery-origin samples is relatively small and could be done as a preventative measure. Truscott said, for instance, proportion of natural origin fish in the broodstock (pNOB) is below the program targets and we don't know whether this is posing a demographic risk. Bill Gale said there is a limited ability to control safety-net fish spawning. For instance, in the Methow River, there is not a good barrier (like Tumwater Dam) to control their passage. Pearsons suggested running the samples from the natural-origin baseline and contemporary natural-origin fish, and if no difference is detected then do not analyze the hatchery-origin fish. On the other hand, if a difference is detected it would be important to know if the difference was due to the hatchery. Pearsons said he supports a stepwise approach that may tell you the effect of the hatchery. Pearsons said the change may also be due to some other impact like a founder effect [in the broodstock for a given year].

Catherine Willard asked how big the difference would need to be between the natural-origin baseline and contemporary natural-origin fish. Pearsons said at this time the intent would be to test the null hypothesis and see if there is a difference. Truscott said it would still be a retrospective analysis on causation every 10 years to provide the confidence that there is no difference between the conservation programs or, alternatively, trigger an analysis of the program practices.

Slide 6: Pearsons said the alternative perspective is to ask whether it is worth investing in something that has limited utility on making management decisions for the program. Pearsons said if there are two completely separate lineages as in other programs, divergence in the genetic identities could be determined to be a result of gene flow over multiple generations.

Slide 7: Pearsons said in the outcomes of the last genetic assessment when hatchery and natural-origin samples were collected, there were no significant differences between hatchery and natural-origin fish. Pearsons said analyzing the hatchery-origin samples didn't add a lot to the discussion or work as an early warning system. Truscott said if there was no difference between hatchery and natural-origin fish, managers would be satisfied with the outcome of the hatchery programs from the genetic perspective. Willard said the previous sampling was a mixture of hatchery and natural-origin fish that may not be representative of the ideal statistical comparison. Hillman said the results from past genetic analyses are in the back of the annual report, which was finalized last week.

Slide 8, Conclusions: The first conclusion states, "*Unless significant differences are detected between baseline and contemporary natural-origin samples, there may be little benefit of running hatchery-origin genetic samples to address genetic M&E objectives*." Pearsons said Grant PUD supports a proposal to follow a stepwise approach. The second conclusion states, "*In cases where differences [between baseline and contemporary natural-origin samples] exist, then it may be worthwhile to run hatchery samples to help evaluate the mechanism of change*." Pearsons said segregated hatchery programs will be monitored differently.

Gale asked whether these samples have already been collected and analyzed for Parentage-Based Tagging (PBT) by CRITFC. Gale said the genotypes have been run and SNP data are available for these programs, perhaps it's just a matter of performing the analyses. Willard said yes, for some but not all populations. Pearsons said natural-origin samples are available for Upper Columbia fall

Chinook, if the Committees chose to run hatchery-origin samples, the samples are probably available.

Kahler said for Methow spring Chinook it would not be obvious what the hatchery-origin fish would be. Would they be hatchery-origin fish sampled on the spawning grounds? Hatchery-origin fish that return to the hatchery? Hatchery-origin fish used in broodstock? Gale said it would include all of those.

It was agreed that sampling of upper Columbia programs for PBT analysis is somewhat comprehensive already for the Chinook and steelhead programs. In the past there has been open sharing of data between CRITFC and USFWS geneticists, and there may be opportunities to analyze data that are already available. Hillman suggested coordinating with geneticists to determine whether samples are available. Pearsons suggested making a decision now about the genetic analysis approach and then determining whether samples are already available. Gale said it will save time to identify where sampling has already been done.

Hillman asked members for their individual perspectives on the need to analyze hatchery-origin fish genetically. Gale said the question of which fish to test as hatchery-origin fish is a major one but tends to agree that that the analysis of hatchery-origin fish should go forward. Murdoch said she supports analyzing hatchery-origin fish when it informs the programs. Mike Tonseth supported analysis of hatchery-origin fish for some programs, but not all. For instance, it may not be necessary for segregated programs, nor non-conservation programs. Tonseth said the Wenatchee steelhead program should be analyzed to determine if there has been an influence because of the inclusion out of basin (Wells stock) fish in the broodstock historically. Brett Farman agreed that collecting more information from hatchery-origin fish in the near-term may prevent long-term genetic impacts. Mackey said he does not see the value of including hatchery-origin fish that are only one generation separated from the natural-origin parents and said it’s complicated because the different programs have different bounds around including natural-origin fish in the broodstock. Mackey said we already have a better dataset on Methow steelhead for a long-term trend analysis using the Twisp RRS study data with 10 years of detailed data available, and there is a valuable long-term data set for analysis of spring Chinook in Methow using microsatellites. Willard said she understands the problems at hand regarding genetic distance resulting from only one generation of hatchery rearing and discerning which fish to test; however, if SNPs are already available, she agreed the samples could be analyzed.

Gale asked if the timing is aligned for analysis of the Methow and the Wenatchee fish? Mackey and Willard said yes, the timing of this analysis is now aligned. Gale said USFWS would like to do similar analyses and follow the same timeline so the outcomes and reporting are aligned for the entire Upper Columbia. He requested to be kept informed on the timeline for analysis.

Hillman summarized that there is a need to discern which programs should be analyzed, what would be compared for each type of program, and whether samples already exist.. Willard said for next year's HCP-HCs Comprehensive Report, collecting new samples is not possible, as that would have to occur now.

Pearsons asked Tonseth whether he was suggesting analyzing listed programs and not analyzing the unlisted programs. Tonseth said yes. Gale said for segregated programs, if the question is whether hatchery-origin fish differ from the natural-origin fish, the answer is yes. Willard said the question is different for segregated programs. Pearsons said the most relevant question is whether or how the hatchery-origin fish are affecting the natural-origin fish. Mackey said there can be multiple causes for differences in the genetics and it's difficult to identify those causes after the fact in order to make management decisions.

Hillman asked if the plan is to analyze the samples that have already been collected and use those to determine genetic differences over time? Truscott said yes, the original intent of genetic analyses was to track changes over time. Truscott said monitoring PNI using the multi-population model was undertaken because it was suspected there were differences between the hatchery-origin and natural-origin fish.

Mackey said the difference is that genetic monitoring evaluates neutral markers and doesn't inform the phenotypic changes between groups that are the result of selection. For instance, traits under selection can change while neutral markers show no change. Conversely, neutral markers may show a shift while traits under selection have remained stable. Truscott asked if this analysis would help us make a different decision about pNOB or pHOS or stray rate targets? Mackey said no, because the PNI concept is concerned with fitness traits that are under selection, but if there were major shifts in neutral allele frequency observed between groups you might be concerned that selective traits were also changing. Or, the neutral marker frequencies may shift while the trait under selection has not changed. The PNI concept is not (directly) concerned with neutral markers. It is focused on traits that are under selection.

Pearsons proposed incorporating the samples that were already analyzed by CRITFC. Willard agreed that this could be done for the Chiwawa spring Chinook program. Pearsons proposed keeping the hypotheses in the M&E Plan focused on natural-origin fish; however, the narrative could report on comparisons to hatchery-origin fish.

Tonseth said there is one disclaimer. DNA is collected on all broodstock except for summer Chinook (Methow and Wenatchee). There is no hatchery-origin lineage for those programs because they are achieving their pNOB targets of 1 and no samples are taken on hatchery-origin fish. Tonseth said natural-origin fish are identified as unclipped without wire tags and origin is confirmed by scale analysis. Gale asked whether hatchery fish returning to Wells Dam for instance, are being bio-sampled. Tonseth said yes, samples are taken to confirm run composition, but the only biological samples taken are scales. Gale said for fish returning to USFWS facilities, they are collecting biological samples.

Hillman suggested following Pearsons' suggestion to delete the hypotheses on sampling hatchery-origin fish for programs in which genetics of hatchery-origin fish is not needed. Thus, the evaluation of hatchery-origin fish would be program specific. Hillman pointed out the section of the M&E Plan, which indicates that hatchery and natural-origin fish from "all programs" will be evaluated for genetics. Gale suggested editing it to say, "all integrated programs." Truscott asked what the nexus would be for genetic sampling if not included in this plan? Truscott asked if the comparison to hatchery-origin fish could begin with the 2017/2018 brood. Willard said yes. Truscott said there were samples collected for the Chief Joseph Hatchery Program that could be included with the Methow summer Chinook analysis. Pearsons agreed there is a need for coordinating the inclusion of all samples. Gale said if only natural-origin fish are included, USFWS would only contribute the samples from steelhead captured in winter and spring for broodstock; if hatchery-origin fish are included, it expands the scope to other programs.

Hillman recorded a placeholder in the target species or populations section of the M&E Plan to focus the hatchery-origin analysis on specific program types. Mackey said he needs time to map out what the relevant programs are and what samples are available. Pearsons asked how the Committees could complete this in time to discern what samples need to be sent for analysis. Hillman said the discussion so far indicates that segregated and unlisted programs would be excluded. Gale said he still questions whether segregated programs should be excluded. He said it may be useful to track whether the contemporary segregated broodstock is similar to or different from the natural-origin baseline and whether the population genetics are shifting over time. Willard said she agrees with Gale and there is a whole set of other questions for segregated programs. Gale said he would rather get this correct rather than rush these revisions and have a report that does not answer the questions at hand.

Pearsons asked whether there is support for moving the completion date for the genetics portion of the comprehensive plan? Kahler said the programs are ready to get started with analyses and it may not require a lot of time to determine which samples are analyzed.

Hillman said this may require identifying and categorizing the different hatchery programs within the M&E Plan and then writing specific hypotheses for each program category. Hillman suggested members craft specific hypotheses for each program category. Willard volunteered to coordinate with other members to develop a draft set of hypotheses for the various programs.

D. Alternative Broodstock Composition and Mating Strategies

Greg Mackey gave a presentation entitled, "*Review of Hatchery Broodstock and Mating Practices for Conservation Programs.*"

Mackey said in previous years a problem originated when encountering limitations on broodstock availability and asking whether jacks should be included in the broodstock. He said the answer to this question became a more comprehensive review of advancements in thinking about broodstock selection and mating strategies.

Slide 2: Mackey reviewed the purpose of conservation programs, which are the following:

- Conserve and rebuild populations
- Minimize negative ecological impacts
- Conserve diversity
- Minimize negative genetic impacts

Slide 3: Mackey said problems have been encountered if the ideal conditions are not met and problems must be worked around; artificial selection is inevitable when fish are propagated in hatcheries.

Slide 4, 5: Mackey identified key factors that contribute to artificial selection in broodstock collection and interaction with fisheries.

Slide 6: Mackey presented data showing the proportion of PIT-tagged Methow spring Chinook lost between Bonneville and McNary dams. Mackey said the data show larger (older) fish are being removed by the fishery, potentially changing the age structure of the populations. Bill Gale asked if jacks are being lost to fisheries, noting that the gill-net fishery is selecting older fish but are jacks kept in the recreational fishery? Mackey said these are spring chinook and there is not a recreational fishery on them that might remove jacks.

Slide 7: Mackey showed that Wells summer Chinook fecundity is on a downward trend in both the wild and hatchery fish and suggested it may be an effect of hatcheries, fisheries, or both. Mackey said he and Mike Tonseth have discussed whether this could be a factor of reduction in size or age at return.

Slide 8: Mackey reviewed published literature on jack contributions to a spawning population. Gale said information from a study by NMFS with steelhead using the Winthrop spawning channel could inform this work. Results are in a Bonneville Power Administration report. Tonseth said the Wenatchee RRS Study data could be leveraged. Mackey agreed getting the best available data to make decisions on incorporation of jacks into the broodstock would be good.

Slides 9 & 10: Mackey provided an example of the potential method for prescribing the contribution by jacks in a broodstock by multiplying jack rate by the typical rate of offspring produced by jacks in the natural environment.

Slide 11: Mackey presented a figure showing the complexities of steelhead mating systems in nature.

Slide 12: Mackey said genetic analysis done to determine if fish deformities observed in Twisp River spring Chinook were isolated to a small number of parents, suggesting a genetic family effect. He said the results showed there did not appear to be a tight connection to a genetic issue. However, in an extension of the original study, Sewell Young (WDFW) found that the Twisp River, a tiny population and a tiny program, has lower rates of homozygosity compared to all Snake River subpopulations. Mackey said small programs are often assumed to carry more genetic risk than large programs, but the population status may not be as bad as is often assumed.

Slide 13: Mackey summarized a large body of literature on strategies for broodstock management.

Slide 14: Mackey said the first general strategy, which he calls the genetically benign approach, seeks to use sufficient numbers of fish to minimize genetic drift and domestication, wild fish in the broodstock (though not necessarily a pNOB of 1), and randomized broodstock selection and spawning to minimize artificial selection.

Slide 15: Mackey said the second general strategy, which he calls emulating natural processes approach, seeks to actively counter artificial selection in hatcheries and fisheries for younger age at maturity, and to emulate mate choice in nature.

Slides 16–19: Mackey presented several other aspects of broodstock management including reviews of the following:

- Typical hatchery mating processes versus typical wild mate choices
- Production of early maturing males increases with use of wild broodstock
- Minimizing kinship
- Equalizing family sizes
- Various potential mating schemes
- Studies showing that humans do not do a great job of "randomly" selecting broodstock

Slides 20: Mackey described the current broodstock collection methods at Methow Hatchery:

- Broodstock collection is (somewhat) random
- Mating follows a 2x2 matrix with males used as backup reciprocally
- Culling only done to control bacterial kidney disease; not to control family size

Tonseth said jacks are not targeted because a size cutoff is used to differentiate age 3 and age 4 males, though some are inadvertently included in the broodstock at rates that could be similar to background levels. Mackey said he and Charlie Snow (WDFW) looked at the Methow spring Chinook data and did not think this was happening. Tonseth said it may be more common in the summer Chinook.

Slide 21: Mackey presented a possible path forward for the Methow Hatchery spring Chinook program, specifically, with several suggestions for consideration:

- Continue to collect brood at random to the best of our abilities
- Continue to use factorial mating protocols with backup males
- Include jacks at a rate they occur in the wild and fertilize eggs from one female at a percent observed in the wild (e.g. 20% of one female's eggs). Todd Pearsons said in some places the practitioners would add milt from one male (jack) in a small area of the mixing container [representative of the typical contribution from jacks on the spawning ground], allow it to fertilize, then mix in milt from full-size males to the rest of the container.
- Ensure time intervals between primary and back-up fertilization to minimize sperm competition
- Follow the model developed by Hankin to preferentially mate females with males that are larger to drive the population toward older age at maturity and larger individuals; however, its unknown the extent to which this can be applied in smaller programs because some fish ripen on different days resulting a numerous smaller spawns than fewer larger ones.
- Use genotypes to avoid close relatedness in matings

Gale said experience suggests that hatchery managers may resist changes because they tend to follow the protocols that provide them the best eye-up rates. Mackey said he talked to Brandon Kilmer (Douglas PUD Methow Hatchery Supervisor) and would work closely with hatchery staff. Mackey said staff at the Methow Hatchery are open to ways to improve.

Pearsons asked how the effects could be measured, for instance, could you select for some trait other than size like the Hankin model? Mackey said they were unaware of any other way to spawn fish together by a phenotype. Pearsons said there are some other patterns informed by the RRS Study work. Mackey said yes, the risk is it would cause really uneven family sizes, magnified by the hatchery process, and potentially exacerbate a Raiman-Laikre effect. Mackey said he would like to try a lot of different things but a constant challenge is balancing the need to stabilize spawning practices while trying to implement something new.

Gale asked if anyone has studied the difference in progeny produced in a spawning channel versus typical controlled hatchery spawning. Mackey said he is not familiar with any such study. Gale said the Winthrop spawning channel produced a significant number of offspring in one study, more than he expected from a relatively small area.

Mackey suggested they would be trying some of this novel approach in the Methow Hatchery program. Gale said there has been a swing toward asking if the genetically benign approach recommended by the Hatchery Scientific Review Group (HSRG) is still the best path forward.

Hillman suggested Committees members share Mackey's review with hatchery managers to start informing them of a desire to improve broodstock selection and mating processes, and to bring them along in the discussion.

Mackey will send the literature review to Larissa Rohrbach for distribution.

E. National Marine Fisheries Service Consultation Update

Brett Farman provided one update. Farman said the permits that Emi (Kondo) Melton (NMFS) had reviewed (the unlisted summer and fall Chinook bundle and steelhead) were sent out for countersignature by WDFW and the PUDs.

III. Wells HC

F. DECISION: 2019 Egg Treatment Study Plan

Greg Mackey reminded the Wells Committee of the components of the draft 2019 Egg Treatment Study that were reviewed in the August 21, 2019 meeting. Mackey said he addressed comments provided by Mike Tonseth regarding oversights or areas that were not written clearly. He said the main goals are to reduce *Saprolegnia* infection and to reduce formalin use at the hatchery. The test carried out at Methow Hatchery in 2018 showed that plain water worked as well as other treatments; however, the eggs may not have been exposed to *Saprolegnia* fungus in the water supply at levels that cause infection. He reminded the Committee that the 2019 study includes a new treatment introduced using elemental copper ions that has worked in other trout hatcheries.

Mackey said he added a table that helped define the treatment groups and their ultimate fate. Mackey said they will try to reduce family effects on the study results by pooling eggs and dividing them into separate groups. He also clarified that 50 eggs from each treatment group tray will be retained and grown to the fry stage to observe latent effects of the treatments.

Study eggs could be surplus to the Wells Hatchery program and made available for other programs, or could be included in the Wells Hatchery production if needed to meet program targets. Fish treated with elemental copper cannot be released due to FDA regulations. Betsy Bamberger inquired with Ecology and FDA to determine rules for releasing fish from copper treated eggs but it was decided that the fish grown from copper treated eggs would not be released. Mackey said he added a column titled "Available for Transfer" to Table 1 that indicates whether eyed eggs at that stage should be available for transfer to other programs or used in the Wells Hatchery program if treated with formalin, water or salt. Keely Murdoch asked if the copper-treated eggs are the only fish that could not be transferred. Mackey said yes, that was their determination at this time.

The Wells HC voted to approve Douglas PUD's draft *Control of* Saprolegnia sp. *Growth on Summer Chinook (*Oncorhynchus tshawytscha*) Eggs, Experimental Protocol – Pilot Study* as final.

IV. Rock Island/Rocky Reach HCs

A. Draft 2020 Monitoring and Evaluation Implementation Plan

Catherine Willard said no additional feedback on Chelan PUD's *Draft 2020 Monitoring and Evaluation Implementation Plan* was received after last month's meeting. Willard added Objective 7 to Table 5 as recommended in the last meeting. Hillman asked if there were any additional edits or comments; there were none.

The Rock Island and Rocky Reach HCs voted to approve Chelan PUD's *Draft 2020 Monitoring and Evaluation Implementation Plan* as final.

V. PRCC HSC

A. Approve the August 21, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the August 21, 2019 meeting minutes as revised.

Tracy Hillman reminded the committees that they are invited to attend the PRCC meeting on September 25, 2019, when Jeff Jorgensen will present aspects of his Wenatchee spring Chinook life-cycle model and respond to questions from the PRCC and PRCC HSC. Keely Murdoch confirmed the meeting is scheduled for 10 a.m. at Wanapum Dam and usually outside presenters are scheduled for the beginning of the day. Hillman said he has requested that a call-in number be provided as well.

Hillman asked whether discussion of any other administrative business was necessary.

Todd Pearsons said the King of the Reach fishing derby will occur on October 25 through 27 [for the collection of Priest Rapids Hatchery Fall Chinook Salmon]. Pearsons said Grant PUD limited entries to 100 boats and the limit was reached in the first week after registration was open.

Tonseth said he has identified an additional topic for the PRCC HSC that should be considered during development of the BCPs. Tonseth said WDFW is still interested in reducing the reliance on the Priest Rapids Dam Off-Ladder Adult Fish Trap for collecting broodstock for the Priest Rapids

Hatchery Fall Chinook Program. Tonseth said WDFW is working toward determining whether enough broodstock could be collected by other means, such as in the King of the Reach derby.

No other business was discussed. Hillman adjourned the meeting.

VI. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are October 16, 2019, November 20, 2019, and December 18, 2019, at Grant PUD in Wenatchee, Washington.

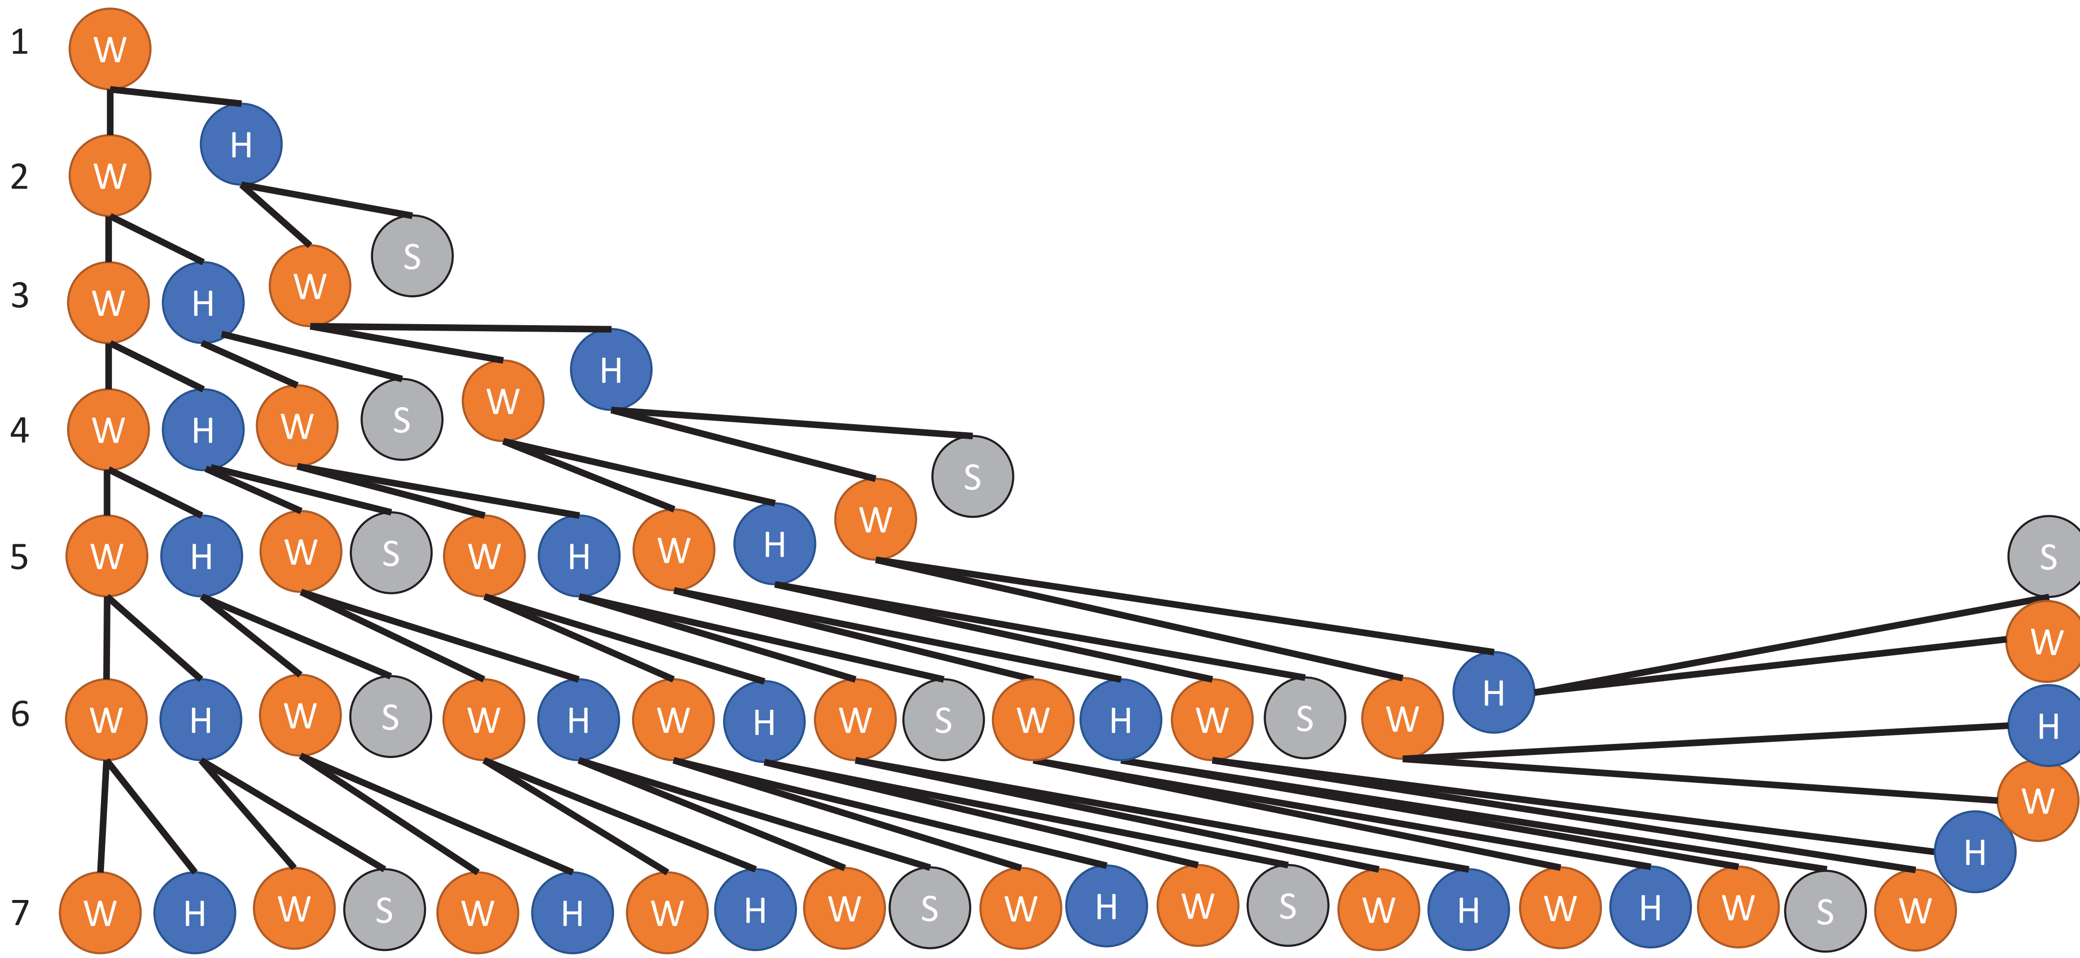
Rationale for using natural origin fish for genetics monitoring in hatchery conservation programs

HC/HSC Meeting, 9/18/2019

Integrated hatchery program definition

- In an integrated hatchery program the hatchery and natural spawning population are part of the same population (they are mixed)
- We attempt to monitor the effects of gene flow from hatchery and natural origin matings
- Our safety net programs are one generation removed from an integrated program and generally don't spawn in nature
- It is highly unlikely that "wild" fish still exist because of all of the mixed matings with different origins

Attachment B



Why natural origin fish?

- The natural origin fish are a good integrator of previous H and N spawnings and they also integrate differences in reproductive success that might occur
- They are the focus of the M&E plan

Genetic risk containment practices reduce the potential for H vs N differences

- Use of natural origin fish as first priority and 1st generation hatchery as second priority for broodstock - Integrated
- Prioritize adult management of returning safety net fish
- Domestication – PNI
- Factorial mating – effective size
- Complex marking and tagging to allow discrimination of different aggregates and conservation/safety net
- Genetic sampling of some broodstock to eliminate strays
- Other

Would sampling of hatchery origin fish give an early warning of differences?

- Unlikely for reasons discussed
- Also, even if differences were detected, how much would it matter if it wasn't reflected in the population at large?
- If differences were detected between H and N, what management actions could be taken?
- Phenotypic measures and genetic indices (PNI, straying) provide early warnings and are estimated annually
- Other

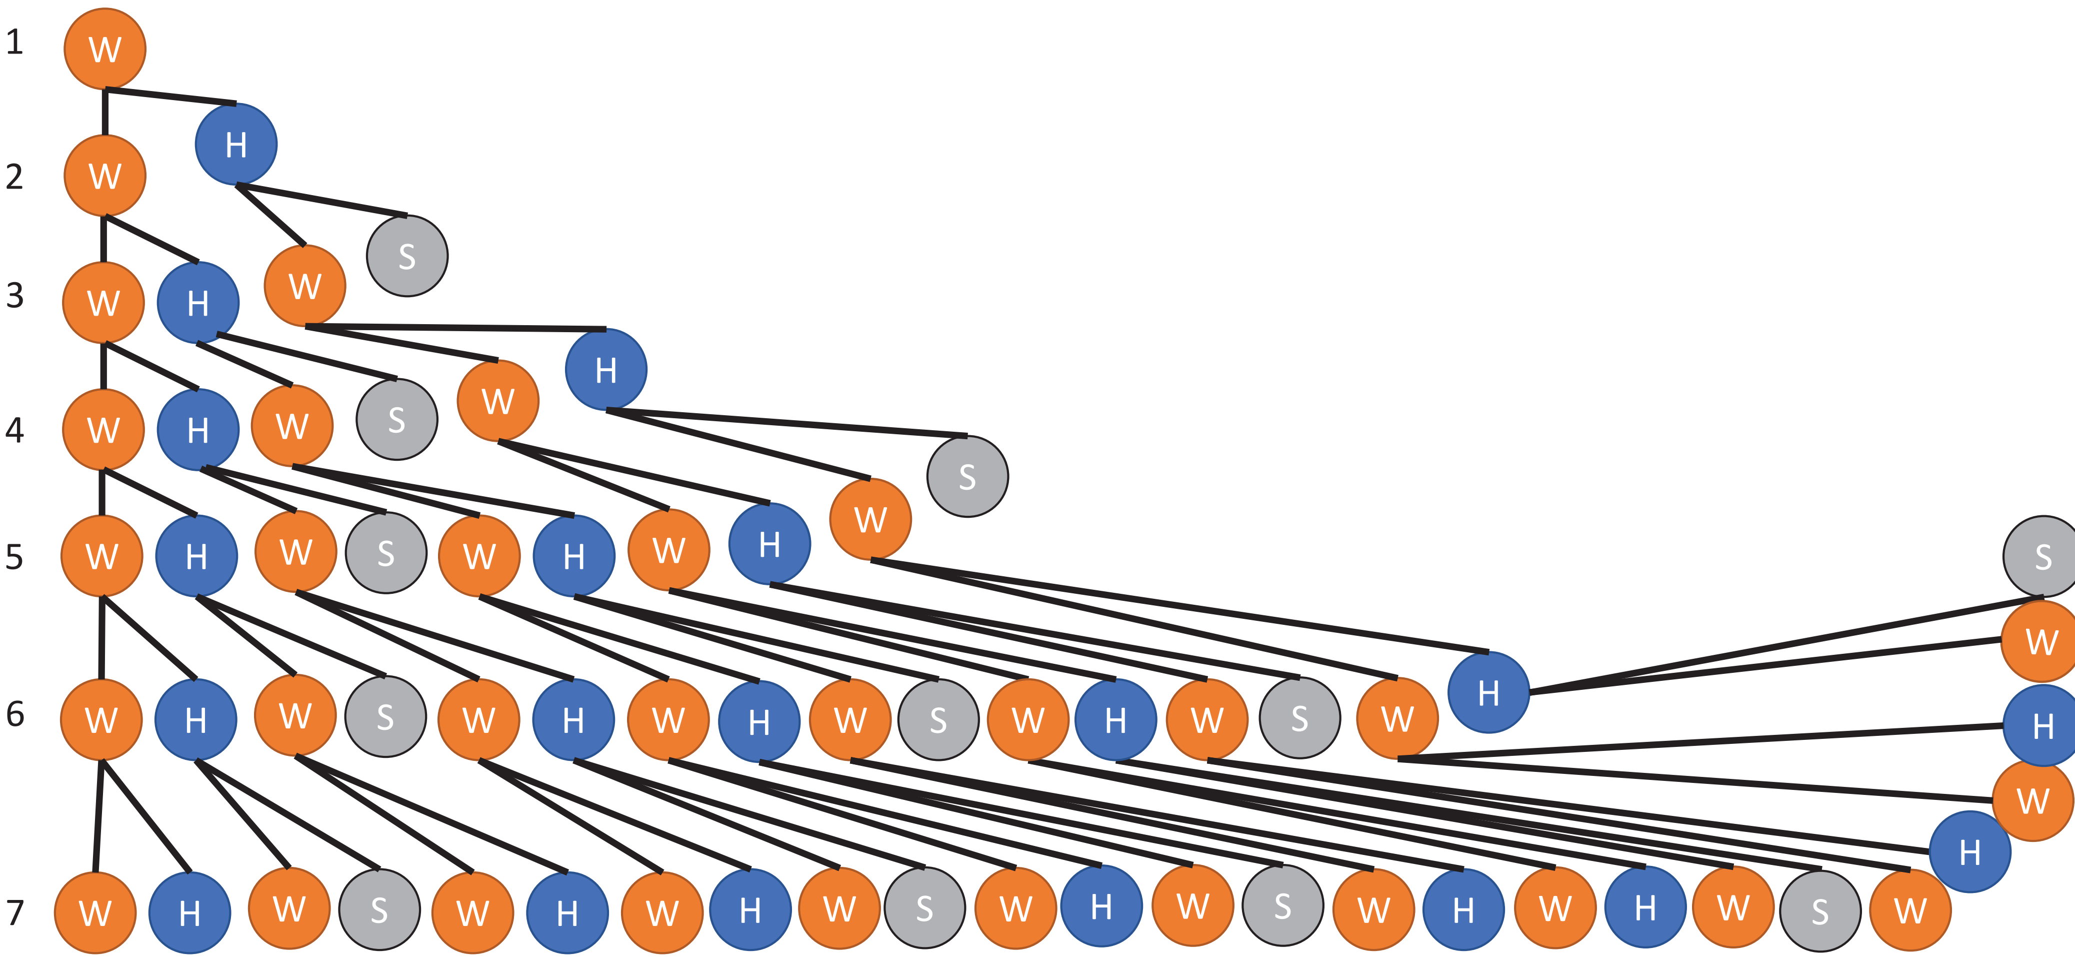
Lessons from last genetic analysis

- Did the presence of H samples in the last genetic analysis increase our understanding of the effects on natural origin fish?
- Did it result in an early warning of problems?
- Did it result in changes in management?

Conclusion

- Unless significant differences are detected between baseline and contemporary natural origin samples, there may be little benefit of running hatchery origin genetic samples to address genetic M&E objectives
- In cases where differences exist, then it may be worthwhile to run hatchery samples to help evaluate the mechanism of change (phased approach)
- Segregated hatchery programs will be monitored differently

Attachment B



Review of Hatchery Broodstock and Mating Practices for Conservation Programs

Greg Mackey
Douglas PUD

September 18, 2019

Conservation Programs

- Conserve and rebuild populations
- Minimize negative ecological impacts
- Conserve diversity
- Minimize negative genetic impacts

Minimize Negative Genetic Impacts

- Artificial selection is inevitable in hatcheries
- How to counter?

Key Factors

- Broodstock Collection
  - Run timing
  - Selection for size, age, sex, appearance, etc.

Key Factors

- Fisheries and Hatcheries
  - Select for younger age at maturity
  - Synergistic because hatcheries allow greater exploitation of mixed stocks which can increase selection on size and age of fish

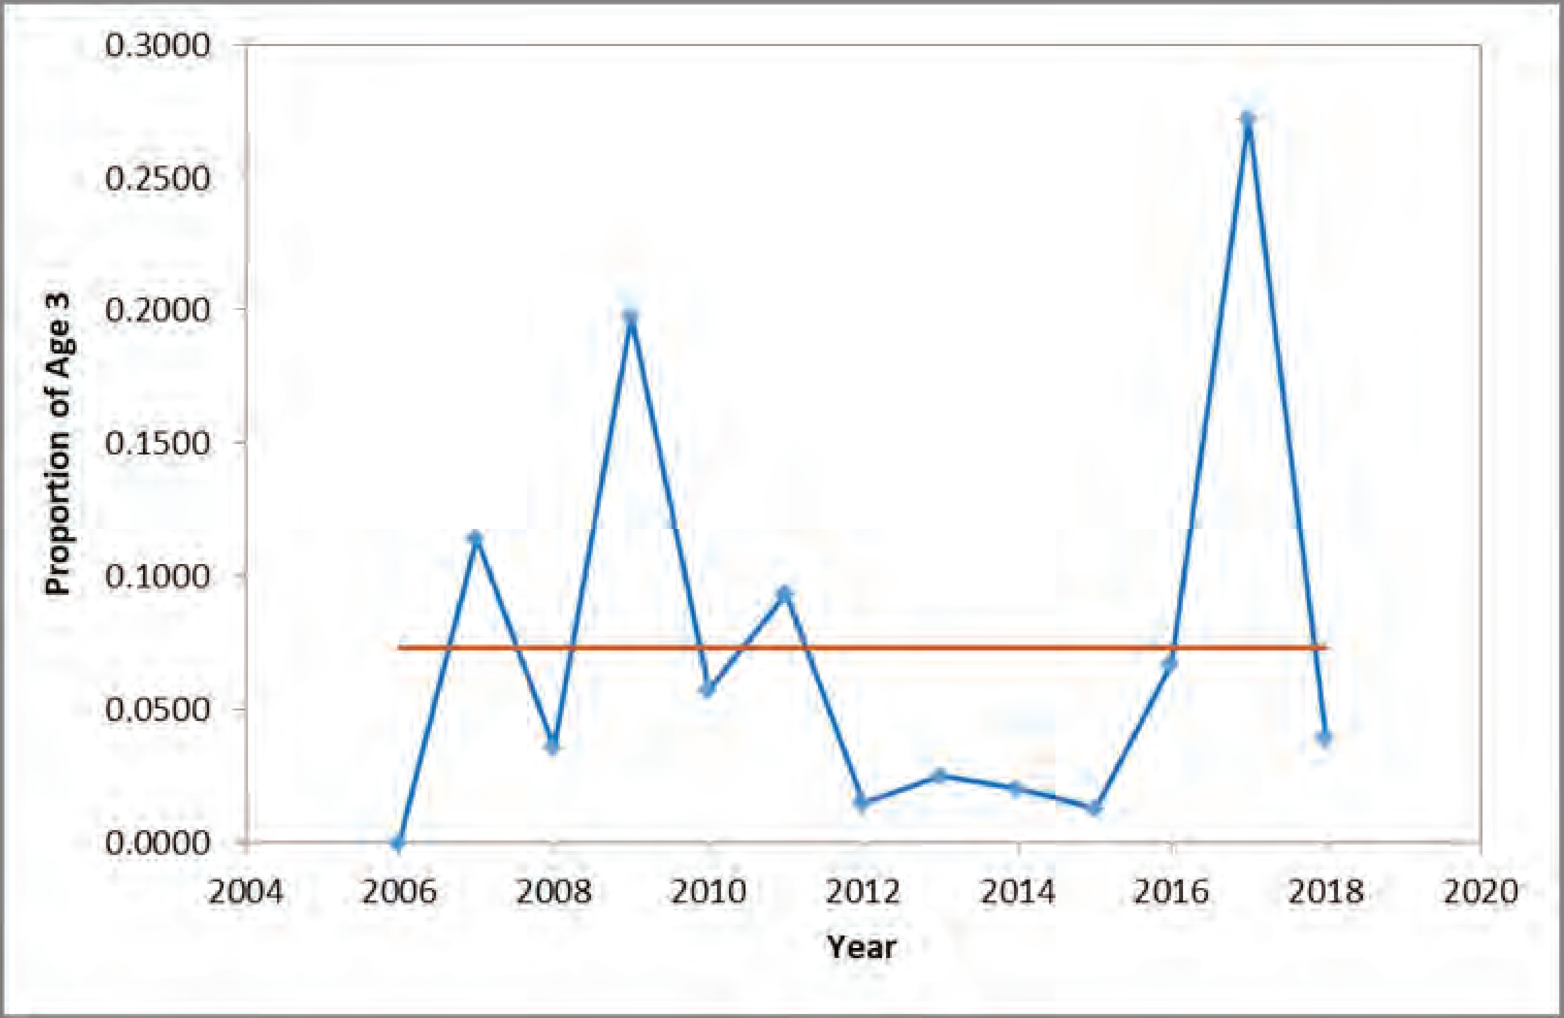
Stating the Obvious – Question of Jacks in Broodstock

- Methow Basin wild jack rate = 7%
- Reproductive success compared to multi-sea winter males:
  - Berejekian et al. (2010) = 20%
  - Schroder et al. (2012) = 3%

Wild Jacks at Wells Dam



Example: Jacks in Broodstock

- 7% * 20% = 1.4% contribution
- 7% * 3% = 0.2% contribution

Strategies for Broodstock Management

- Two overall Strategies:
  - Genetically Benign Approach
    - Campton 2004; HSRG 2004
  - Emulate Natural Processes Approach
    - Hankin 2009; Quinn 2005

Genetically Benign Approach

- Sufficient broodstock population to overcome drift, domestication.
  - Wild fish used to prevent divergence
- Random broodstock collection without regard for phenotype
    - Run-timing, size, age, etc.
- Minimize artificial selection in hatchery
- Mating Scheme
  - Spawn fish randomly: without regard to age, size, etc.

Emulate Natural Processes Approach

- Counter artificial selection in hatchery for younger age at maturity
- Counter fisheries effect for younger age at maturity
- Emulate mate choice structure found in wild
  - Spawn females with larger males to drive population towards older age at maturity

Other Aspects of Broodstock Management

- Key processes in hatcheries (Quinn 2005):
  - Broodstock collection
  - Mate choice and gamete collection
- Larsen et al. (2019)
  - wild broodstock produced early maturing males at higher rate than broodstock with as little as one generation of hatchery ancestry
- Minimize kinship
  - Best way to maintain genetic diversity in captive programs (Ivy and Lacy, 2012)
- Equalize family sizes

Other Aspects of Broodstock Management

Mating Schemes

a. Random Pairwise 1:1
   i. All adults have equal opportunity to reproduce
b. Overlap Pairwise
   i. Backup male used
   ii. Sperm competition can still occur even 45 s after first fertilization.
c. Pooled
   i. Sperm competition
   ii. Loss of control over mating scheme – not recommended by anyone.

Other Aspects of Broodstock Management

d. Pooled Matrix
   i. Multiple females' eggs mixed and separate into aliquots. Separate males fertilize each aliquot.
   ii. Greater potential for disease transmission
   iii. Cannot track family groups for disease management or performance analysis

e. Nested
   i. For skewed sex ratio 1:2 or more
   ii. Recommendation is to collect more fish so the less abundant sex meets minimum broodstock needs and excess of the abundant sex are discarded.

f. Factorial (Matrix) (Busack and Knudsen, 2007)
   i. 2x2, 3x3, 4x4 etc.
   ii. Maximizes number of family groups and genotypic diversity
   iii. Maximizes effective number of breeders in the hatchery

Other Aspects of Broodstock Management

Random Selection

- Likely during mating, brood are not randomly chosen in terms of phenotypic traits (Mclean et al. 2005).

"Despite efforts by the staff to not spawn selectively, data on steelhead spawned over 7 years revealed selection for large adult body size and early reproductive timing and a tendency for size-assortative mating (i.e., large with large). Selection on size was related to selection on reproductive timing because early returning fish tended to be larger than those returning later."

Current Conditions – Methow Hatchery

1. Broodstock collection is (somewhat) random
   a. Attempt to collect brood across the entire run timing, but the realities of trapping a small population and to minimize the number of fish trapped and handled tend to front load the trapping to ensure enough brood are captured.
   b. Injured or sick fish may not be retained
   c. Jacks are not retained (except in 2019 the Broodstock Protocols)
2. Mating follows a 2x2 matrix with males used as backup reciprocally.
   a. Small program limits the range of possibilities for matrix spawning.
   b. Fish to be mated are chosen at random by staff, but it is likely they are not randomly chosen in terms of phenotypic traits (Mclean et al. 2005).
3. Culling
   a. Families are not culled to equalize family size.
   b. Culling may be performed to control BKD

Possible Path Forward – Methow Hatchery Programs:

1. Broodstock collection
   a. Brood collection to be random (to the best of our abilities).
   b. Jacks included in collection at a pre-determined rate; (e.g., up to 7%; see below).
2. Mating
   a. Continue to use factorial mating protocol with backup male
      i. Ensure enough time has passed between primary and backup fertilization to prevent sperm competition (>>45s).
      ii. Jacks to fertilize only a partial aliquot of each female mate's eggs (e.g., 7% of the females will have up to 20% of their eggs fertilized by jacks [results in about 1.4% of all eggs being fertilized by jacks])
   f. To the extent possible, follow the protocol in Hankin et al. (2009) where larger males are preferentially mated with smaller females to select for older age at maturity to counteract effects of hatchery propagation and fisheries.
3. Use genotypes to avoid close relatedness in matings.

Subject: Clarification of Extension of the Wenatchee spring Chinook RRS Study

Adult management activities at Tumwater Dam began in 2014. As a result, the abundance and proportion of hatchery spawners has and is expected to differ from what has been included in the study thus far (Table 1). For example, the abundance of naturally produced fish has never exceeded that of hatchery fish. In addition, the parental origin of hatchery spawners will also be changing such that only hatchery fish produced by natural origin parents could be allowed upstream to spawn. Furthermore, the sex and age of hatchery fish allowed to spawn naturally may also differ annually if jacks and adult male hatchery fish are disproportionately removed at Tumwater Dam. These significant hatchery reform actions are the reasons we (WDFW and NOAA) proposed extending the duration of study to BPA. These reform actions will be empirically evaluated as these additional brood years are included in the study. WDFW and NOAA is asking for approval from the Rock Island HCP Hatchery Committee for the clarification in change in scope/duration.

Table 1. Summary of the number and percentage of hatchery and naturally produced fish allowed to spawn upstream of Tumwater Dam, 2004 – 2013. Asterisk denotes preliminary numbers that may change after scales are read.

Year	Hatchery		Naturally produced	
	Number	%	Number	%
2004	1,327	0.60	898	0.40
2005	3,217	0.84	594	0.16
2006	1,600	0.74	573	0.26
2007	3,259	0.91	324	0.09
2008	5,338	0.89	631	0.11
2009	4,270	0.85	777	0.15
2010	4,453	0.83	880	0.17
2011	4,792	0.80	1,224	0.20
2012	4,010	0.75	1,370	0.25
2013*	3,274	0.75	1,144	0.25
Mean	3,554	0.79	842	0.21
CV	36	12	39	45

Proposed Action (as clarified)

Extend the scope/duration of the study to include brood years 2014 through 2018. However, comparisons of relative reproductive success will only be made at the smolt stage via DNA sampling of natural origin smolts collected at smolt traps through 2020 and DNA sampling of natural origin adults at Tumwater Dam through 2023 (i.e., 2018 brood). The goal is to sample 100% of the natural origin smolts encountered at smolt traps and as many natural origin adults as possible up to 100% of the return during this period. A comparison of the original proposal and proposed extension is provided in Table 2.

Table 2. A summary of additional impacts directly attributable to the study as a result of the proposal.

Question	Original Project	Proposal
Last brood year in study?	2013	2018
Last year of DNA sampling potential hatchery spawners?[1]	2013	2018
Last year of DNA sampling wild returning adults?[1]	2018	2023
Last year of juvenile DNA sampling?	2015	2020
Last year of intensive spawning ground surveys?	2013	2013

[1] Denotes last year of adult trapping specific to the RRS Study but does change trapping activities that may be associated with adult management, broodstocking, and/or other M&E related activities.

ESA Take and Permitting

Section 10 permit #18121 provides all of the necessary take associated with the extension. Furthermore, because the removal of excess hatchery fish at Tumwater Dam and the collection of DNA from naturally produced fish (i.e., original RRS study) will also require trapping effort (and scheduling) similar to past years efforts under the RRS, the trapping effort for adult management and DNA collection under the original RRS scope of work will be sufficient to conduct the study. The change in scope will result in the additional sampling (i.e., biological data, PIT tag, and DNA) of natural origin adults through 2023 and the DNA sampling of naturally produced juveniles collected at smolt traps that otherwise would already be sampled and PIT tagged through 2020.

Other Logistical Considerations

Results of the study thus far have suggested that spawning location accounts for a significant proportion of variation in reproductive success. Chelan County PUD currently conducts spring Chinook spawning ground surveys in the Wenatchee Basin. As such, WDFW will work closely with PUD staff and supply the equipment and supplies necessary to ensure the any additional data critical to the study (i.e., spawning location of all carcasses not just females and DNA from untagged fish) is collected consistent with past protocols.

Approval of this extension has already been approved by BPA. At this time we are formally seeking approval from the Rock Island HCP Hatchery Committee for the clarification in scope to include natural origin adult DNA sampling at Tumwater Dam through 2023 (2018 brood). If there are any potential questions or issues with the clarification of the study extension/duration please feel free to contact me at your convenience.

Rock Island and Rocky Reach HCP Hatchery Committees
Final Statement of Agreement
Annual Broodstock Collection Protocols

Approved as follows: Chelan PUD, WDFW, USFWS, NMFS, YN and CCT approved on September 18, 2019

In fulfillment of requirements of existing and forthcoming Endangered Species Act permits for the Rock Island and Rocky Reach Habitat Conservation Plan (HCP) Hatchery Programs, the Rock Island and Rocky Reach HCP Hatchery Committees (HCP-HCs) agree to develop and submit to the National Marine Fisheries Service (NMFS) annual Broodstock Collection Protocols each year by April 15. The purpose of this agreement is to provide an annual schedule that allows for adequate discussion and review of plans prior to approval of the protocols.

Process and Schedule: The Permit Holders will prepare a draft Broodstock Collection Protocol for review by the Rock Island and Rocky Reach HCP-HCs no later than 10 days prior to their respective February meetings. Following Committees review and revision, a final Broodstock Collection Protocols will be subject to approval at the March HCP-HCs meetings and submitted to NMFS by April 15. The HCP-HCs will reevaluate this schedule in August 2020 and determine if changes are necessary.

Timeline:

- September HCP-HC meetings: Initial flagging/introduction of major changes/deviations/issues to existing programs/methods/schedules/etc. to the respective committee(s). Individual assignments outlined.
- No later than November 15: Individual BSP assignments due.
- December HCP-HC meetings: Finalization of discussions/agreements relating to major changes proposed in September by the respective committee(s).
- No later than January 10: Internal permit holders draft circulation for review
- No later than 10 days prior to the respective committee(s) February meetings: First draft circulation of Broodstock Collection Protocols for committee representative review/commenting.
- March Rock Island and Rocky Reach HCP-HC committee meetings: Approval of final annual Broodstock Collection Protocols
- No later than April 15: Submission of final approved annual Broodstock Collection Protocols to NMFS and USFWS.

NMFS/USFWS Approval: Participation in the development, submission, and approval of the annual Broodstock Collection Protocols within the Committees by the NMFS/USFWS HCP-HC representatives will constitute NMFS/USFWS acceptance and approval of the annual Broodstock Collection Protocols.

SOA 2019-01

Priest Rapids Coordinating Committee's Hatchery Subcommittee
Final Statement of Agreement
Annual Broodstock Collection Protocols

Submitted to PRCC Hatchery Subcommittee: 8/21/2019
Approved by PRCC Hatchery Subcommittee: 9/18/2019

In fulfillment of requirements of existing and forthcoming Endangered Species Act permits for the Priest Rapids Project Salmon and Steelhead Settlement Agreement (SSA) and National Marine Fisheries Service (NMFS) Biological Opinion, the Priest Rapids Coordinating Committee's Hatchery Subcommittee (PRCC-HSC) agrees to develop and submit to NMFS annual Broodstock Collection Protocols each year by April 15. The purpose of this agreement is to provide an annual schedule that allows for adequate discussion and review of plans prior to approval of the protocols.

Process and Schedule: The Permit Holders will prepare a draft Broodstock Collection Protocol for review by the PRCC-HSC no later than 10 days prior to the February meeting. Following Committee review and revision, a final Broodstock Collection Protocols will be subject to approval at the March PRCC-HSC meeting and submitted to NMFS by April 15. The PRCC-HSC will reevaluate this schedule in August 2020 and determine if changes are necessary.

Timeline:

- September PRCC-HSC meeting: Initial flagging/introduction of major changes/deviations/issues to existing programs/methods/schedules/etc. to the respective committee(s). Individual assignments outlined.
- No later than November 15: Individual Broodstock Collection Protocols assignments due.
- December PRCC-HSC meeting: Finalization of discussions/agreements relating to major changes proposed in September by the respective committee(s).
- No later than January 10: Internal permit holders draft circulation for review
- No later than 10 days prior to the respective committee(s) February meetings: First draft circulation of Broodstock Collection Protocols for committee representative review/commenting.
- March PRCC-HSC committee meeting: Approval of final annual Broodstock Collection Protocols
- No later than April 15: Submission of final approved annual Broodstock Collection Protocols to NMFS and USFWS.

NMFS/USFWS Approval: Participation in the development, submission, and approval of the annual Broodstock Collection Protocols within the Committees by the NMFS/USFWS PRCC-

HSC representatives will constitute NMFS/USFWS acceptance and approval of the annual Broodstock Collection Protocols.

Wells HCP Hatchery Committee
Final Statement of Agreement
Annual Broodstock Collection Protocols
September 18, 2019 meeting

In fulfillment of requirements of existing and forthcoming Endangered Species Act permits for the Wells Habitat Conservation Plan (HCP) Hatchery Programs, the Wells HCP Hatchery Committee (HCP-HC) agrees to develop and submit to the National Marine Fisheries Service (NMFS) annual Broodstock Collection Protocols each year by April 15. The purpose of this agreement is to provide an annual schedule that allows for adequate discussion and review of plans prior to approval of the protocols.

Process and Schedule: The Permit Holders will prepare a draft Broodstock Collection Protocol for review by the Wells HCP-HC no later than 10 days prior to the February meeting. Following Committee review and revision, a final Broodstock Collection Protocols will be subject to approval at the March HCP-HC and HCP-Coordinating Committee[1] (HCP-CC) meetings and submitted to NMFS by April 15. The HCP-HC will reevaluate this schedule in August 2020 and determine if changes are necessary.

Timeline:

- September HCP-HC meeting: Initial flagging/introduction of major changes/deviations/issues to existing programs/methods/schedules/etc. to the respective committee(s). Individual assignments outlined.
- No later than November 15: Individual BSP assignments due.
- December HCP-HC meeting: Finalization of discussions/agreements relating to major changes proposed in September by the respective committee(s).
- No later than January 10: Internal permit holders draft circulation for review
- No later than 10 days prior to the respective committee(s) February meetings: First draft circulation of Broodstock Collection Protocols for committee representative review/commenting.
- March Wells HCP-HC and HCP-CC committee meetings: Approval of final annual Broodstock Collection Protocols
- No later than April 15: Submission of final approved annual Broodstock Collection Protocols to NMFS and USFWS.

NMFS/USFWS Approval: Participation in the development, submission, and approval of the annual Broodstock Collection Protocols within the Committees by the NMFS/USFWS HCP-HC and HCP-CC[1] representatives will constitute NMFS/USFWS acceptance and approval of the annual Broodstock Collection Protocols.

[1] HCP-CC approval meets the Wells HCP requirement for approval of broodstock collection and monitoring and evaluation activities involving the Wells Project facilities.

Control of *Saprolegnia* sp. Growth on Summer Chinook (*Oncorhynchus tshawytscha*) Eggs

Experimental Protocol – Pilot Study

Written by Dr. Betsy Bamberger, DCPUD Fish Health and Evaluation Specialist

Abstract: To be completed at the conclusion of the study.

Introduction: Water mold (*Saprolegnia* sp.) is a common pathogen of salmonid eggs in fish hatcheries. Traditionally, hatcheries have used formalin for prophylactic management of *Saprolegnia* sp. infection in incubating eggs. However, formalin has long been associated with worker safety and environmental hazards, and may be met with increasing scrutiny by regulatory agencies in the immediate future. In 2018 we conducted a similar study at the Methow Hatchery and found no differences among treatments. However, it is likely that *Saprolegnia* sp. load was low, limiting the inference that study could provide. We propose a similar study at Wells Hatchery, where it is thought the risk of *Saprolegnia* sp. infection will be higher than at Methow Hatchery, potentially providing more contrast in the results. In this study, we investigate the efficacy of purported alternatives to formalin that can be used as safe therapeutic substitutes. These alternatives include hydrogen peroxide (H_2O_2), salt (NaCl), and slow-release elemental copper (Dr. Nicole Walrath, personal communication, July 11, 2019), as well as no treatment (i.e., chilled or ambient water only), and will be tested for control of water mold infestations during salmonid egg incubation under hatchery conditions at Wells Fish Hatchery (WFH). The study described here is a pilot study. The null hypothesis is there will be no difference found between test treatment groups (hydrogen peroxide, sodium chloride, elemental copper, and no treatment [water]), and the formalin group, using egg mortality caused by Saprolegniasis as the basis for the analysis.

Methods: Thirty-five females and thirty-five males of Wells Hatchery-origin (hatchery) summer Chinook will be collected at Wells Fish Hatchery (WFH) in 2019 and progeny will be incubated as per the Wells hatchery subyearling program. The fish are in addition to the Wells Hatchery subyearling program. Once sexually mature, the adult fish will be stripped of eggs and milt in mid-October 2019. All gametes will be harvested on the same day to eliminate temporal bias. Eggs from each female will be collected in a Ziploc® bag and weighed; these weights will later be added to determine a total egg weight. Once all are harvested, green eggs and ovarian fluid from spawned females will be combined into a shallow communal tub (a 45 in diameter plastic kiddie pool) and gently mixed. Eggs will then be divided into thirty-five approximately equal portions by weight, resulting in each aliquot being similar to typical fecundity of an individual female (each deposited into a separate, numbered large Ziploc® bag) and placed in an ice-filled cooler lined with burlap. Milt from each male will be collected in separate Whirl-Pak® bags and stored in the same chilled cooler. Each bag of eggs will be infused with milt from an individual male, used for primary fertilization, and then milt from a second male used as backup several minutes after initial fertilization by the primary male. Each male will serve as a primary male for at least one female and a backup male for one or more females, thus providing greater probability of successful fertilization and minimizing the effect of an individual with reduced viability or non-viable gametes.

Eggs and milt will be mixed within each bag, placed in a designated individual Heath vertical incubator tray, and then gently rinsed with water, consistent with general hatchery practice for production programs where one female's eggs are loaded per tray Trays will be placed within a stack assigned to one of five treatment groups (formalin, salt, hydrogen peroxide, elemental copper, and ambient water [no treatment]).

The total number of eggs in the formalin, salt, hydrogen peroxide, elemental copper, and no treatment (water) groups is 140,000 eggs (35 * 4,000 average fecundity = 140,000). Of these, 28,000 eggs will be incubated with the subyearling production program and will serves as the formalin treatment, and the remaining 112,000 eggs will serve as the salt, hydrogen peroxide, elemental copper, and no treatment (water) groups (see Table 1).

Table 1. Schedule of summer Chinook broodstock needs, eggs, unfed fry, transfers, euthanization.

Treatment Group	Number of Broodstock Pairs	Number of Eggs	Number Retained to Unfed Fry	Available for Transfer	Number to Transfer (up to)	Number to Euthanize
No Treatment	7	28,000	50	Yes	27,950	50 fry
Formalin	7	28,000	50	Yes	27,950	50 fry
Salt	7	28,000	50	Yes	27,950	50 fry
Hydrogen Peroxide	7	28,000	50	Yes	27,950	50 fry
Elemental Copper	7	28,000	50	No	0	27,950 eggs 50 fry
Total	35	140,000	350		118,000	350 fry 27,950 eggs

Five incubation stacks will be used, one for each of the five treatment groups. The topmost tray of each stack will be kept empty to allow for ease of chemical introduction; the seven trays below will be reserved for eggs (see treatment-specific information and schematic representation of experimental set-up in Figure 1, below). The formalin stacks will be located in a separate incubation room (Incubation Room #5) to avoid potential adverse chemical reactions between formalin and hydrogen peroxide; all other stacks will be located in Incubation Room #7. Egg clutches will be placed within trays in sequential order until all trays are occupied. For all treatments, the fertilized eggs in the trays within the stacks will be water-hardened and disinfected in a 100 ppm buffered iodophor (Ovadine®) solution (static bath) for 60 minutes as per standard procedure. Following water hardening and surface disinfection, fresh well water (averaging 55°F) will be introduced into the stacks, effectively draining away the used iodophor solution from each tray. TidbiT® temperature data loggers will be added to the top most tray of each stack to record and track water temperatures throughout treatment. Flow will be set at 2.5 gallons per minute (gpm). Incubating water temperatures will be cooled from 55°F (well water) to 40.5°F over a 10 day period and then kept at 40.5°F for roughly two weeks, after which the temperatures will be brought back up to 55°F over a three day period (this mimics Wells' standard incubation procedure for subyearling smolts).

Salt and hydrogen peroxide will be added to the topmost (empty) tray of the incubation stacks and delivered via a metered peristaltic pump (INTLLAB™ or MasterFlex easy-load® II). Formalin will be administrated via the flow lines and venosets built into Incubation Room #5. Copper pads will be added into and evenly distributed within the topmost tray of the incubation stack. Dosages of hydrogen peroxide, formalin, and salt will be calculated to consider flow rate, treatment time, final desired concentration of chemical treatment, and chemical strength. As such, treatments will be consistent with FDA-label instructions/allowances or previously published data (see Figure 1). Salt will be pre-dissolved before administration; salinity will be monitored during treatment with an Apera 5052 saltwater salinity tester with the probe placed in the topmost empty tray and recorded twice during administration (5 and 15 minutes).

Daily 15-minute flow-through treatments with hydrogen peroxide, well water, and salt will be initiated on the day following fertilization. Treatments will continue daily and cease just prior to the initiation of hatching, providing approximately XX days of treatment.

When the eggs are at approximately 550 temperature units, the incubator trays in all stacks will be opened and photographed to document the degree and spatial distribution of any *Saprolegnia* sp.-infected and/or dead (opaque) eggs. The eggs will then be shocked by mechanical agitation within the trays and infected and/or dead eggs will be removed and counted before trays containing the remaining live eggs are returned to the stacks. An average individual egg weight will be estimated from a 100 egg sample of the remaining live eggs from 10 random trays. This average egg weight will be used to estimate the number of live eggs for each tray.

From each treatment group, 50 eggs will be from retained each tray and combined into one tray to incubate to the unfed fry stage (350 per group; 4 groups *350 = 1,400 to be destroyed as unfed fry). The remainder of the eggs will be transferred to other programs or destroyed or (see below). Mortality from eyed egg to unfed fry for each treatment will be assessed when the unfed fry are determined to be near ponding readiness. Staff will check for discernable morphological differences in unfed fry from each group to determine if histological analysis is warranted.

Eyed eggs from the salt, hydrogen peroxide, and no treatment groups may be transferred to other programs upon consent from the Hatchery Committee. Eggs from the formalin, hydrogen peroxide, salt, and no treatment groups will either be incorporated into the Wells Hatchery subyearling release group if the program will remain under 110% of the production target, or transferred to other programs. Eggs from the elemental copper treatment must be destroyed according to FDA rules.

The criteria used to evaluate the efficacy of each compound will be 1) mortality from fertilization through eyed egg (which includes both water mold-infected eggs and dead uninfected eggs throughout the incubation period and after shocking) and 2) eyed egg to unfed fry survivability. In addition, the extent of water mold infection will be qualitatively (via photography) and quantitatively (via the number of eggs that appear infected) estimated and enumerated, respectively.

No Treatment 100% Well Water	**Hydrogen Peroxide** 35% PEROX-AID® Dosing regimen: 1000 mg/L for 15 minutes (~488 mls H202) in a continuous flow system once per day (consistent with FDA label). Administration: 32.5 ml/minute (or 0.54 ml/second)	**Sodium Chloride** Diamond Crystal® Solar Naturals® Dosing regimen: 20,000 ppm for 15 minutes (~8 lbs salt per stack) in a continuous flow system once per day (based on findings in Waterstrat, 1995 and Edgell, P. and D. Lawseth, 1993). Administration: Make a 3 lb of salt/1 gallon of water stock solution; 0.2 gal/min	**Elemental Copper** Chore Boy® Copper Scouring Pads Dosing regimen: 12 pads per stack (12.4 g each). Application permissible by the FDA via the Code of Federal Regulations Title 21 pertaining to new animal drugs for investigational use (21 CFR 511.1.a).	**Formalin** Parasite-S® Dosing regimen: 1/600 (1,666 ppm) for 15 minutes (~770 ml per stack) in a continuous flow system once per day (consistent with FDA label). Administration: 51.3 ml/minute (or 0.85 ml/second)

Figure 1: Schematic representation of incubation room, stack and tray assignment, and dosing regimen per treatment group.

Statistical Analysis: One-way ANOVA will be used to examine similarities or differences between treatment groups using trays as a replicate. Tray position will be tested to rule out a tray position effect on mortality prior to analysis of treatment effect.

Results:

Discussion: This study is a pilot study to test the experimental methodologies at Wells Hatchery and to gain preliminary results regarding the efficacy of various treatments that may control *Saprolegnia* sp. infection of Pacific salmonid eggs. The results of this study will be combined with the results of a similar study conducted at Methow Hatchery in 2018 to inform future research direction in pursuit of testing alternatives to formalin for fish health applications in a hatchery setting.

Conclusion:

Acknowledgements: Special thanks to the Wells Fish Hatchery staff; Greg Mackey; and Andrew Gingerich for their help in completing this pilot study.

Re: Final Minutes of the October 16, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, October 16, 2019, from 9:00 a.m. to 3:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery (MFH) programs (Item I-A). *(Note: this item is ongoing.)*
- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will work with Mike Tonseth to test a modeling approach and prepare a white paper on the method for determining a range for the number of females to be collected for a given broodstock in the upcoming year (Item II-C).
- Brett Farman will confer with Charlene Hurst and confirm whether transfer of surplus spring Chinook salmon eyed-eggs from MFH to the Colville Confederated Tribes' 10j program is consistent with the intent of the 10j permit (Item II-D).
- Bill Gale will confirm whether Winthrop National Fish Hatchery (WNFH) can receive surplus spring Chinook salmon eyed-eggs from MFH (Item II-D).

- Mike Tonseth will prepare, and Larissa Rohrbach will distribute, the Appendices to the Broodstock Collection Protocols (BCPs) for editing by the relevant parties that were identified in the October 16, 2019 meeting (Item II-E).

Decision Summary

- There were no decisions made in today's meeting.

Agreements

- The HCP HCs and PRCC HSC agreed to allow scientists to report the carcass survey data at the historic reach scale for comparison to past results, and also to report the data at a scale that is appropriate for each reach and population to discern distribution trends.

Review Items

- Larissa Rohrbach sent an email to the Wells HCP-HC on September 16, 2019, notifying them that Douglas PUD's draft 2018 Monitoring and Evaluation (M&E) Report for the Wells and Methow program is available for 60-day review with edits due by Friday, November 15, 2019 (Item I-A).
- Larissa Rohrbach sent an email to the PRCC HSC on October 22, 2019, notifying them that Grant PUD's draft 2018-2019 Priest Rapids Hatchery M&E Annual Report is available for 30-day review with edits due by Friday, November 20, 2019 (Item I-A).

Finalized Documents

- There were no documents finalized in today's meeting.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the September 18,2019 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC to the meeting.

Hillman asked for any additions or changes to the revised agenda (distributed via email by Larissa Rohrbach on October 14, 2019).

Attendees requested to add several items for discussion to the agenda.

- Hillman asked to discuss the scale of carcass survey analysis in the Comprehensive Report (due in 2020). This would follow the discussion of updates to the genetics section of the M&E Plan.
- Hillman added that the Committees would offer performance evaluations for himself and Rohrbach in today's meeting (under administrative business).
- Todd Pearsons added conference announcements to the administrative business.
- Mike Tonseth added consideration for changing start time of the meetings to the administrative business.
- Greg Mackey added a discussion on the disposition of surplus Methow Hatchery spring Chinook salmon eyed eggs. Hillman said this would be discussed as part of the surplus juvenile production discussion (Item II-D).

The HCP-HCs and PRCC HSC members approved the revised agenda.

The HCP-HCs and PRCC HSC representatives reviewed the revised September 18, 2019 meeting minutes. Additional minor revisions were made in the meeting. The HCP-HCs and PRCC HSC members approved the meeting minutes as revised.

Administrative business was discussed.

Tonseth asked if the start time could be shifted to 10:00 a.m. to accommodate logistical challenges related to school schedules. Bill Gale suggested accommodating the schedule in the winter but reverting back to a 9:00 a.m. start time in the summer. Gale asked if the school schedule has always been the same and is unlikely to change in the future. Tonseth and Keely Murdoch said it is unlikely to change. All parties agreed to changing the meeting start time to 10:00 a.m. during school months (September through May). During other months, the meeting will start at 9:00 a.m.

Pearsons said the Upper Columbia Science Conference will occur on January 22 and 23, 2020, in Wenatchee, Washington, and abstracts are currently being reviewed. Pearsons said the Western Division American Fisheries Society meeting will be held in Vancouver, BC, on April 12 through 16, 2020, with abstract submission open through November 8, 2019.

Hillman noted that it is time for the HCP-HCs to provide an evaluation of his and Rohrbach's performance. Greg Mackey asked how the Committees members would like to convey feedback to Hillman and Rohrbach. Mackey said generally the feedback was positive. The following feedback was provided to Hillman over email:

Mackey said the HCP-HCs conducted an evaluation of the Chair, Tracy Hillman. Mackey said the PUD representatives polled all the members by email offering opportunity to reply directly or request a conference call or meeting to discuss the Chair's performance. All members replied via email that they were pleased with the Chair's performance and wanted Douglas PUD and Chelan PUD to retain Hillman's services for another three-year term. Hillman agreed to serve as the Chair for the Wells, Rocky Reach, and Rock Island Hatchery Committees for another three years.

Mackey also provided a positive review of the meeting support services provided by Rohrbach in 2019. Pearsons noted that applying the same approach to maintaining the meeting records for the PRCC HSC has been successful for ensuring meeting discussions were accurately summarized.

Action items from the HCP-HCs and PRCC HSC meeting on September 18, 2019, were reviewed, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on September 18, 2019)*:

Joint HCP-HCs and PRCC HSC

- *Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present pre-spawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A).*
  Tonseth said this item is ongoing; there may be pre-spawn mortality values for females but not yet for males.
- *Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A).*
  Truscott said this item is ongoing.
- *Brett Farman will discuss with Charlene Hurst (NMFS) and Tonseth the potential use of a multi-population model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A).*
  Farman said he contacted Hurst and Tonseth to initiate a discussion, but the item is still ongoing.
- *Greg Mackey will distribute a white paper reviewing broodstock composition and mating strategies for conservation programs, focusing on spring Chinook salmon at the Methow Hatchery (Item I-A).*
  This item was distributed by Larissa Rohrbach on October 14, 2019, with a request that any comments or edits be provided to Mackey, and is attached to these minutes as Attachment B. This item is complete.
- *Larissa Rohrbach will add HCP Policy Committee guidance on policy-level issues to the HCP-HC Meeting Protocols (version dated May 15, 2019; Item I-A).*

Tracy Hillman said the final meeting minutes were distributed on September 26, 2019. [Rohrbach updated the HCP-HC and PRCC HSC Meeting Protocols following the meeting and distributed an updated version on October 22, 2019. This item is complete.]

- *Mike Tonseth will distribute a suggested drafting plan for the Broodstock Collection Protocols (BCPs) assigning specific members to address topics for discussion; Tracy Hillman will determine whether there is a need for an additional conference call in early October to discuss research needs to address given topics (Item II-B).*
  Tonseth said this will be discussed in today's meeting. This item is complete.
- *Catherine Willard will coordinate with other HCP-HC and PRCC HSC members to draft separate sets of genetic monitoring hypotheses that are specific for the individual hatchery programs to monitor for changes in population genetics over time (Item II-C).*
  Tracy Hillman said this item will be discussed in today's meeting. This item is complete.

PRCC Hatchery Subcommittee

- *PRCC HSC representatives will submit a list of minimum data or information needs for making a decision on the White River spring Chinook salmon hatchery program to Tracy Hillman (Item I-A).*
  Hillman said this item is ongoing because the PRCC is working on the direction for the HSC. This action will be removed from the list until further direction is provided by the PRCC.
- *Brett Farman will ask Craig Busack (National Marine Fisheries Service [NMFS]) to participate in PRCC HSC process for identifying data needs and making a decision on the White River spring Chinook salmon hatchery program (Item I-A).*
  Farman said Busack is willing to participate to some extent but would like to address focused questions if possible. Farman said Busack's retirement date is in February. Hillman suggested discussing potential questions for Busack in the HSC meeting.

II. Joint HCP-HCs and PRCC HSC

A. Genetics Updates to the Monitoring and Evaluation Plan for PUD Hatchery Programs

Tracy Hillman projected the edited version of the genetics section (Objective 7) of the PUDs' Monitoring and Evaluation Plan (M&E Plan) in the meeting. Catherine Willard said she did not receive feedback on the most recent revisions [distributed by Rohrbach on October 4, 2019] and shared her edits to the document.

Willard summarized the discussion the Committees had in the previous meeting, that there is an interest in analyzing genetic changes of hatchery-origin returns. The original question focused on the analyses of natural-origin returns exclusively. Willard stated that she captured the analyses of hatchery-origin returns by modifying the Objective 7. Willard said the agreement during the last meeting was that different types of programs would ask different questions about genetic changes over time. She shared edits to the M&E Plan narrative about adding segregated programs to the analyses to convey that segregated programs desire to monitor the risk of using multiple generations of hatchery-origin fish in their broodstock. Willard added a monitoring question about segregated programs (Questions 7.1.1 and 7.1.2) with relevant hypotheses that apply to the modified monitoring question. Willard said she removed the equivalence testing hypotheses and added language that states that biologically relevant effects for measured differences in genetic metrics have not been determined to date, and when they are, the equivalence testing hypotheses equations could be added back to the document. Hillman said he had added language to the narrative on the purpose of equivalency testing and application to many of the hypotheses (also in response to Independent Scientific Advisory Board [ISAB] feedback). Hillman asked if the Committees wanted to approve sections of the document as they are completed or approve the entire document once all ISAB feedback is incorporated. Keely Murdoch asked if there could be a need to make more changes after review of the other objectives. Hillman said changes can always be made because it is a living document. Hillman said a benefit of approving this section separately is that it would allow the programs to move forward on planning genetic analyses.

Greg Mackey said he is not ready to approve the section because he still needs to take time to map out the hatchery samples that would be analyzed and whether that type of analysis would inform the Douglas PUD programs. Mackey summarized the conclusion from the last meeting that in conservation programs the parents of the hatchery fish are wild so the “hatchery fish” are the offspring of wild parents such that any changes observed would be stochastic (essentially sampling error) and not necessarily informative of what the neutral markers should tell us (shifts in the genetic status of the population). Mackey agreed that with incorporation of contemporary natural-origin fish into the conservation programs, comparisons of the contemporary natural-origin fish to the natural-origin baseline makes sense to monitor for genetic changes away from the baseline.

Willard summarized the struggle to understand whether hatchery fish should be analyzed but also noted the conclusion from last month’s meeting was to go forward with analyzing hatchery-origin samples. Todd Pearsons said a contingency of voting to approve this section of the M&E Plan may be to allow the Committees to re-evaluate whether to analyze the hatchery samples once the value of that information is better understood.

Mackey said he would be willing to approve the M&E Plan in sections. Pearsons said it would be best to standardize versions with a single publication date so that they are easily referenced in other documents. Mackey said in 2021 there will be another rewrite of the M&E Plan and asked what sections may need changes. Hillman said major changes are not needed, just revisions to respond to

ISAB feedback. The genetics section was different from others because there were major changes to the hypotheses proposed. Mackey asked about the Before-After-Control-Impact (BACI) analysis. Hillman said description of the BACI analysis is in an appendix to the M&E Plan and that descriptions within the M&E Plan should be sufficient. Willard noted that revisions to the genetics sections address a discrepancy in what the M&E Plan said would be done to analyze the effect of hatchery programs on natural populations and the intent of the plan.

Hillman posed a general question. He said salmon adapt to local environmental conditions. In some cases, this may mean that genes coding for non-adaptive phenotypes are lost because of natural selection (i.e., homing and local adaptation reduce genetic variation). He asked if those genes are actually lost, or are they retained but not expressed (the genes or histones or both are methylated). Murdoch asked if Hillman was referring to hatchery-rearing effects or in selective pressures in the wild. Hillman said the question applies to both hatchery and natural rearing. Murdoch said one of the confusing factors is that in a hatchery there shouldn't be genes lost because individuals [or their genes] are not being lost to competition as they would be in the wild. Bill Gale said the testing for allele frequency evaluates changes to the DNA template; however, in other cases, such as age at maturity, gene expression is affected by rearing in the hatchery.

Hillman referred to a case where Chinook salmon ova from the Sacramento River were transplanted to New Zealand (series of publications by T.P. Quinn, M.J. Unwin, and M.T. Kinnison). These fish survived and evolved into several populations, each with unique heritable traits (e.g., different fecundities, age at maturity, length at age, migration timing). Apparently, these fish retain high genetic diversity (or experienced significant positive genetic mutations) and simply express those genes that result in phenotypes that improved survival within the different river systems. Given the founder effect and the rapid rate at which these fish evolved, this seems to be a case of differential gene expression rather than a loss (or increase) in genes or alleles. Hillman said the hypotheses in the M&E Plan focus on gene frequency. Clearly, a loss of genes or alleles is not good, but maybe the genes are not lost. Perhaps they are retained in the nucleus and simply not being expressed. Gale said presentations like that given by Mackenzie Gavery (NOAA Fisheries Northwest Fisheries Science Center; presented to the HCP-HCs on May 17, 2017) on epigenetic changes that can transfer across generations indicate that allele frequencies should not be the only monitoring target.

Mackey said it's important to keep in mind that the genetic monitoring is focused on neutral markers, alleles that are lost by chance (i.e., genetic drift) not by selection, that are used as a proxy for the selection process that causes a loss of diversity that may occur due to hatchery processes. Mackey said selection occurs for genes that confer fitness. He also noted that selection only selects "against" genes, not "for" genes, so genes that are not selected against should remain in the population. Only genes that are selected against would be driven to low levels or lost. Mackey said in summary, genes are unlikely to be lost except in very small populations. Mackey said it would also be interesting to investigate further the co-adapted gene complexes brought into a population when population mixing occurs. Mackey said selection is not perfection, it just has to be good enough.

Hillman said the intent of his question was to help identify effect sizes for equivalence testing. Mackey said the science is progressing rapidly for identifying selective markers in fish.

Spatial Scales for Carcass Survey Analysis

Hillman said another question related to the M&E Plan is what the appropriate spatial scale is for analyzing hatchery and natural-origin female carcass distributions. Currently, carcasses are recorded using GPS in the field and then the spatial distribution of natural-origin and hatchery-origin carcasses are analyzed statistically at the 100-meter (m) scale following criteria in the M&E Plan. Hillman said it is difficult to depict a long reach of river (e.g., 40 kilometers [km]) graphically if carcass distribution is analyzed at the 100-m scale. Hillman said in the last comprehensive report, spring Chinook salmon carcasses were analyzed at the 500-m scale. Hillman also said that the smaller the scale, the more likely it is to observe a statistical difference between groups.

Murdoch said she thought in the previous M&E Plan the data were analyzed by river kilometer. Willard read from the M&E Plan that states spatial analyses should be done at the historic reach scale and at the 100-m scale. Mackey said they have done both scales and that the boundaries of the historic reach designations can be arbitrary, or not biologically relevant (e.g., based on convenient river entry points). Willard said Douglas PUD reported the average of the river kilometer at which hatchery and natural-origin female carcasses were observed, while Chelan PUD reported the frequency distribution of carcasses. Willard and Mackey said it makes more sense to report the frequency. Hillman said management decisions could be different when looking at the data at the 100-m, 500-m, or 1-km scale. Pearsons said it depends on the program. For instance, spatial distribution of fall Chinook salmon would be very different than spring Chinook salmon. The original metrics were developed for spring Chinook salmon and in some cases the metrics have not been a good fit for the other species. Pearsons said it also depends on the reach, and the way that carcasses drift. Using the 100-m level of analysis gives a false sense of confidence in carcass locations. Mackey said the other problem with precision is that the field staff may carry the carcasses before marking their location by GPS. Willard, Gale, and Murdoch said their biologists mark the location by GPS before moving the carcass to collect other biological data (e.g., size, scales). Pearsons said data collection using GPS allows the data to be analyzed in many different ways. Peter Graf agreed and said the data should be binned according to what is appropriate for the population, stream, or reach. Mike Tonseth agreed that there should not be a “one size fits all” approach for all sites and stocks. For instance, a smaller tributary like Nason Creek versus the Hanford Reach of the Columbia River should have different scales of inference. Hillman said that he does not see much value in analyzing carcass data at small spatial scales (e.g., 100 m). Gale asked if the distributions were actually being tested statistically. Hillman said yes. The p-values are generally smaller when analyzing the data at the smaller scales [indicating higher probability of statistically significant difference].

Tonseth said it is necessary to use different spatial scales for analyzing spring Chinook salmon and steelhead compared to fall Chinook salmon just because of the size of the sites, populations, and carcass drift in certain reaches. Hillman said he was hopeful that there could be a general approach that would be applied for all stocks or populations. Pearsons suggested retaining the data collection approach that allows for flexibility, starting analysis at a broad spatial scale, and if differences are not observed, then moving to a smaller spatial scale.

Murdoch read from the original analytical framework (prior to updates in 2013), which states the analysis should be done at 0.01 km (10 m). Murdoch read that the original framework states that statistical analysis should be done by origin and sex, but analysis by sex would not actually be done if males are not analyzed. Murdoch said the original test was intended to be a comparison of averages of river kilometer and the data were broken out by reach for visualization. Hillman said an ANOVA (Analysis of Variance comparison test) could be used but this approach ignores useful distribution data. With ANOVA, year and origin are independent variables. Willard asked whether the original analytical framework was updated in 2013. Mackey and Tom Kahler said yes. Murdoch asked what updates have been made over time to the M&E Plan. Willard said the more recent updates included graphic and Chi-squared analysis. Mackey said one reason comparing means was not working was because the distributions were not normally distributed. Mackey said in some cases statistics are not even needed to see the differences.

Hillman suggested moving forward by deciding whether a prescriptive approach should be written into the M&E Plan, or whether the analysts should be allowed to determine the scale for each stock and location. Graf suggested starting at 500 m and adjusting to minimize noise in the data and ensure the data are not overly clumped. Pearsons said he supports stating that analyses should be carried out at "an appropriate scale," for instance, analyzing data at 500 m does not show anything for Hanford Reach Fall Chinook salmon and would not be appropriate for that stock. Pearsons said analyzing the data by the historic reaches allows for evaluation at the largest scale, and then it should be up to the analyst to decide what smaller scale is appropriate.

Mackey said presenting the data by historic reaches presents the context. Gale said the historic reaches should not be the only default analysis method because the boundaries may not be biologically relevant. Murdoch said the time scale associated with the historic reaches is much longer and has a larger dataset and therefore should be preserved. Graf suggested leaving it to each analyst to explain why a certain scale is chosen and report at the scale that is most appropriate for a given location and population.

Gale said choosing how to bin histograms is always a problem and there are not great statistical tools to make decisions on where to separate the bins. Hillman said there are some statistical packages that do this, but he does not recommend the approach.

Agreement: The HCP HCs and PRCC HSC agreed to evaluate female carcass distribution data at the historic reach scale for comparison to past results, and also allow analysts to report distributions at a scale that is appropriate for each location and stock.

Kirk Truscott said this discussion pertains to longitudinal trends [along the river channel] but there could also be an interest in analyzing the data across the channel. Hillman agreed and said that probably pertains more to redd distribution and less to female carcass distribution. Survey crews are not assigning redds to a specific origin of fish.

B. Improvement Feasibility at Eastbank Hatchery for Wenatchee Summer Chinook Salmon SOA

Catherine Willard said that in 2016 the Rocky Reach/Rock Island HCP HCs approved a statement of agreement (SOA) to include chilled, partial water reuse at Eastbank Hatchery to help with rearing fish and to meet Wenatchee River Total Maximum Daily Load (TMDL) requirements for phosphorous discharge limits, specifically from hatchery production at Dryden Acclimation Pond adjacent to the Wenatchee River. Ian Adams presented information from the SOA and process that has led to a different approach for meeting the TMDL requirements for the Dryden Acclimation Pond.

Ian Adams gave the presentation entitled, "*Chelan County PUD Dryden TMDL Compliance*" (Attachment C).

Slide 2: The 2016 SOA indicated that phosphorous discharge limits from Dryden Pond would be met by rearing Wenatchee summer Chinook salmon to a smaller size. The SOA states, "This would be accomplished by constructing a new chilled partial water reuse system at Eastbank Hatchery utilizing circular ponds as a successfully demonstrated rearing practice prior to transfer to the Dryden Acclimation Pond for final spring acclimation."

Slides 3, 4: In 2012, after receiving an addendum to the TMDL from the Washington State Department of Ecology (Ecology), Chelan PUD took five preliminary actions to attempt to address phosphorous discharge from Dryden Pond. The final SOA moved forward with investigating feasibility of chilled partial reuse system at Eastbank Hatchery in order to grow smaller fish that would release fewer pollutants.

Slide 6: Secondary actions included modifying feeding practices, rearing Wenatchee summer Chinook salmon to a smaller size with existing infrastructure, and further negotiations with Ecology, in particular, regarding the background phosphorous levels in the Wenatchee River that exceeded thresholds for the TMDL [not including discharge from Dryden Pond].

Slide 7: Feeding methods were adjusted to hand-feeding rather than broadcast feeding with a mechanized blower system to avoid over-feeding. The fish were switched to a low-phosphorous feed (lowest levels commercially available). Adams said the low-phosphorus feed is difficult to acquire. Bill Gale said they have moved away from using this feed at Leavenworth National Fish Hatchery (LNFH) because of difficulty of acquiring the feed. Adams said they worked closely with staff at Eastbank Hatchery to reduce the size of fish during early incubation prior to transfer to Dryden Pond (previous target was 10 fish per pound, now 18 fish per pound; the hatchery typically achieves 16 fish per pound). Phosphorous discharge over years from 2012 to 2019 was shown. Feeding, early growth, and stocking methods were adjusted each year. Phosphorous levels have remained below TMDL thresholds over four consecutive years.

Slides 8,9: Adams said new Ecology staff have helped Chelan PUD to clarify the terms of their TMDL and to edit the terms of the TMDL so they are more easily interpreted. Ecology also allows for the dismissal of background phosphorous content from Dryden discharge samples.

Slides 10, 11: Some additional benefits were observed by reducing flow through the Dryden Pond per guidance from WDFW fish health on industry standards for flow indices. Water quality auto samplers were installed at Dryden Pond intake and outflow. Data are sent to Ecology once monthly during “Critical Season” months (March and April) as defined by Ecology.

Kirk Truscott asked whether the existing circular reuse at Eastbank was instrumental in adjusting fish size prior to transfer. Adams said that was not the biggest effect. The bigger effect was better management of fish reared in raceways. Only about 20% of the fish are in the circular ponds.

Gale asked whether the conversation with Ecology was difficult regarding removal of background phosphorous levels from the baseline. Adams said the conversation was difficult in the past but was more productive in recent years. Gale said LNFH will have to consult with the U.S. Environmental Protection Agency for a similar Clean Water Act Section 404 permit. Gale said there is a similar problem in Icicle Creek for LNFH, but the data that are the bases for the TMDL are out of date and he is interested in determining whether Ecology will be renewing the TMDL using more recent data.

Peter Graf said one of the other problems with the criteria that were provided for Dryden Pond is that the phosphorous load is spiky and there was no temporal element to the criteria provided in 2012.

Truscott asked how reducing flows through Dryden Pond helped to meet the TMDL; one would think the contrary would be true due to more dilution by higher flows. Adams said the change in phosphorous load allocation with flow is not linear. Phosphorous load criteria values are higher per CFS at lower flows than they are with increased flow values (shown in Slide 7). Adams said the criteria are limits for total discharge per day, so lower flows reduced total daily discharge and the phosphorous with it.

Adams said in the one year that flow had been dropped in half, the fish health issues that had occurred for several years were not exhibited. Mike Tonseth said when the flows were higher, it caused fish to move to the side of the pond and resulted in higher densities around the edge of the pond. Tracy Hillman said there are terms for this: "ecological density" versus "crude density." Truscott suggested that perhaps fewer mortalities and decaying fish may have reduced phosphorous discharge too.

Gale asked if Ecology provided options for how water quality is sampled. Adams said the options were to manually take two grab samples once per week during a normal work day and composite them, or to take hourly samples over 24-hours for one day each week and composite them. Gale said that is similar to sampling at LNFH.

Hillman thanked Adams for his presentation.

Hillman concluded the discussion by stating that because Chelan PUD is meeting their TMDL, the 2016 SOA on Improvement Feasibility at Eastbank Hatchery for Wenatchee Summer Chinook salmon is not needed.

C. Establishing ranges around broodstock collection targets

Greg Mackey said in 2013 he gave a presentation showing a modeling approach for determining the number of broodstock adults that would be required to meet juvenile production targets for the upcoming year. Mackey said modeling was originally done in Excel using PopTools but became hard to manage in Excel, so he rewrote the model code in R. Mackey said he then ran a number of scenarios through the model.

Mackey gave a presentation entitled, "*Managing Risk and Expectations in Broodstock Collection*" (Attachment D).

Slides 2, 3: Mackey showed the basic broodstock calculation: multiply the number of adult females desirable by a number of factors (e.g., pre-spawn survival, fecundity) to determine number of smolts produced. One can test iterations with different numbers of females to achieve the number of smolts desired. However, each of those factors in the equation has a mean and associated variance that were calculated from annual data sets.

Slide 5: When using a random draw from the distribution of each factor, it is unlikely a given value will be the mean of the distribution. If variances are large, choosing an individual value farther away from the mean is more likely.

Slide 6: Mackey calculated the percentage for how often a parameter would fall +/- 10% outside the mean for each factor.

Slides 7,8: Histograms depict the distributions of the various factors. One approach is to choose the number of females that might work, or alternatively one can ask the model to identify a number of females. One would choose the number of model iterations that would be run to determine an ideal number of females.

Slide 9: Running model iterations allows one to test allowable critical values for the number of females necessary and estimate the probability of achieving the target number of smolts while staying below 110% of the target.

Slide 10: Effect of population size. At very low program sizes the number of females needed to create an overage can be very small (e.g., if only 13 females are required, one additional could create an overage).

Slide 11: Data inputs. A database could be maintained for factors like survival and fecundity, then R can calculate statistics from the data.

Slide 12: Data distributions for factors considered for yearling summer Chinook salmon.

Slides 13–16: Results. Figure shows number of females (x) by probability of meeting a target (y), along with probability of exceeding 100% permitted production. The ideal result would maximize probability of meeting the program target and minimize probability of creating a surplus. The curve shows optimum number of females for meeting program size without exceeding permitted program size (producing a surplus number of juveniles). One use would be to apply the model and look back at whether the calculations of factors, such as fecundity, were accurate. This information could also be given to managers to identify targets for meeting program size or used to identify a range of numbers to give managers some flexibility in number of fish collected.

Gale asked if Bacterial Kidney Disease (BKD) culling was included in the data. Mackey said it is part of the model but was not used for this simulation. Mackey said you could include the percentage collected assuming culling would occur.

Slides 17–19: Key Concepts. PUD programs do not want to routinely fall below targets and fail to meet mitigation obligations; however, going over targets poses problems like collecting too many wild adults for broodstock or needing to find a home for surplus juvenile fish.

Mackey concluded by saying he would like to start using this model in the 2020 BCPs to identify target numbers.

Willard asked whether the optimal numbers identified by the model matched the current targets in the BCPs. Mackey said some of the data for various factors he used from monitoring reports was slightly different than what was in the BCPs. Tonseth said in recent years a geometric mean has been reported rather than arithmetic mean to de-emphasize the extreme high and low values. Tonseth said sometimes different pre-spawn mortality values are reported for males and females of hatchery-origin and natural-origin fish. Mackey said this year is a good example of a case for spring and summer Chinook salmon when fish were quite a bit bigger with higher fecundities than what was assumed in the BCP. Tonseth said in some programs (e.g., steelhead), fecundity has been highly variable and problematic to predict. For instance, within one age class, fish would come back at the same length but different body condition; perhaps there is a different metric that could be collected like fish girth behind the pectoral fin to associate with fecundity that would be a more predictive metric of fecundity than length (measured as post-orbital to hypural length). Tonseth said when fecundity is that much higher, it does not take many females to create an overage of thousands of eggs. WDFW does not want overages, which are especially problematic for listed fish.

Todd Pearsons asked whether the 10% overage limit is an annual target or rolling target and whether it is captured in agreements. Tonseth said that is an annual target and is written into the permit language. The 90% minimum to meet the mitigation credit has been the PUD's obligation. Pearsons said a 5-year rolling average is used to report PNI. Is the 90% target a rolling average or an individual year? Gale said it is an individual year but is not specifically worded in other agreements like *US v. Oregon*. The conversation has always assumed that 10% below targets is always a trigger for regulatory actions. Gale said the other way this is evaluated is a total adult production (TAP) goal; no range is offered, but TAP reported on an annual basis would likely be aggregated over 5 years because of variability due to ocean conditions. Pearsons said the target number of juvenile releases is really a sensitive metric and it is hard to hit the target, so a rolling average over 5 years, for instance, may be a more appropriate way to evaluate whether targets have been met.

Truscott said there are also cases where targets are not met because of production issues that affect only 1 year. If the method Mackey proposes is used and something happened during production, then the method might be in question. Truscott acknowledged the range provided for meeting program levels offers some flexibility.

Tonseth said the approach he uses is a back-calculation from target number of smolts to the number of adult females needed for the broodstock. Mackey said conceptually it is the same math, just running the calculations in reverse compared to the method presented today. Tonseth suggested going through the conventional approach and the approach developed by Mackey, and then comparing the outputs.

Hillman said the challenge is to provide a single target to the fish culturists. Tonseth said in-season monitoring of the return will be evaluated to determine if the target should change. Steelhead are the most variable. Gale said the strength of Mackey's method is allowing managers to see what variable is driving the selection of number of females, and the factors input into the model could be targeted based on what is known about a given run, like BKD load; a value slightly higher than the mean could be selected for that factor. Pearsons asked Tonseth if the latitude should be given to the fish culturists ahead of the season or should changes be made in-season by the Committees. Tonseth said M&E specialists are sampling the fish for length and fecundity in season and can recommend adjustments in season. Tonseth said if the change was large, he would advise bringing the decision for discussion in the Committees. Mackey confirmed that the original goal was to provide a range of acceptable targets in the BCP; Tonseth said the State would hesitate to give the fish culturists that flexibility because they will choose the maximum every time. Mackey confirmed that a very small spring Chinook salmon program should not be over-collected, but for larger summer Chinook salmon programs, they could notify the Committees that extra fish are being retained. Tonseth said he would rather see fish culturists subsample some individuals to confirm assumptions about the factors that greatly affect production before collecting more fish in excess of target numbers.

Hillman asked what the next steps for this topic should be. Mackey said he would like to work with Tonseth to test the method further and prepare a white paper for use across the programs. Mackey said he would like to try it for the Douglas PUD programs. Tonseth said he would like to couple the method with a proposal for one of the programs in the 2020 BCPs.

Hillman thanked Mackey for his presentation.

D. Surplus Juvenile Production

Tracy Hillman provided background on the topic, which Douglas PUD originally distributed an email on September 20, 2019, regarding out-planting surplus juvenile steelhead to a non-anadromous lake. The surplus juveniles were offspring of hatchery-by-hatchery crosses from the Methow Safety Net (MSN) and Columbia Safety Net (CSN) programs.

Keely Murdoch reiterated concerns she had originally expressed via email that although the Yakama Nation (YN) approved the anticipated methods for distribution of surplus juveniles listed in the BCP, there was no chance to discuss this particular decision in the Committees, and a decision was made rather quickly. Murdoch said the release of surplus juvenile salmon and steelhead to non-anadromous waters should be a very last resort. Murdoch said she would have liked to find a different program to accept these fish and an adequate discussion for the potential for release of the fish to the Columbia River. Murdoch said there is an irony that the Committees are comfortable releasing an extra 500,000 to 1 million subyearling summer Chinook salmon to the Columbia River for orca but no discussion was had for releasing 50,000 juvenile steelhead. Murdoch said she was unclear why this was such a rush. There is an advantage to holding fish longer to ensure that nothing unexpected happens during rearing that reduces numbers such that program targets for release numbers are not met. Murdoch said she feels those conversations could have been had in the Committees. Hillman acknowledged that that topic was not brought to the Committees for discussion in the last meeting.

Brett Farman clarified that for NMFS the willingness and the desire to release additional juveniles are not interchangeable positions. NMFS would prefer not to reconsult on the permits that were very recently finalized if they do not need to. Farman said, for the surplus steelhead, this was a discussion of a listed stock, whereas for increasing summer Chinook salmon numbers, we are talking about a non-listed stock. Farman said he does not support releasing fish in areas where they were not intended to be either; however, he is constrained by the Biological Opinion on the hatchery programs that identifies different effects of releasing fish in anadromous waters. Murdoch agrees that she also is not necessarily interested in re-opening consultation. However, for example, when unintended mortalities occasionally happen that exceed the "take" provided in the Biological Opinion, typically a letter is written to NMFS that safeguards will be put in place and other reasons such a loss will not happen in the future and the programs move on. Murdoch asked whether the release of surplus juveniles to anadromous waters could be handled in a similar manner.

Farman said he sees this differently, that the first case describes incidents that are not predictable, and in the second case the "unforeseen overage" is not really unforeseen; 110% of program size is intended to be the upper limit to an overage, but over time it can end up becoming the target. Murdoch said she disagrees that in this case 110% of program size was used as the target. There are many factors with ranges around the normal results that make it difficult to predict exactly the number that will be produced. Murdoch said this surplus resulted from things that happened that were outside managers' control.

Mike Tonseth said this surplus resulted from protocols used for the 2018 broodstock. Tonseth reminded members that the Committees approved a BCP in 2018, which affects the 2019 broodstock, that identified a steelhead overage to be collected in the fall as backup, in addition to the target number of adults to be collected to support safety-net programs. Tonseth said it was identified for all members that fall collections of steelhead would always result in a surplus. Murdoch said if that is the case, additional broodstock should not be collected in the spring to limit surplus. Tonseth said the CCT want to prioritize the spring collection for Okanogan River releases because the

MSN and WNFH adult returns cannot be sorted out at Wells Dam, and those destined for the Okanogan River can only be collected/identified in the spring. Tonseth said the 2020 broodyear (described in 2019 BCPs) should be the last broodyear with an acknowledged surplus prior to spawning. Tonseth said those mechanisms are in place, developed by WDFW, for dealing with that overage, which is why the Hatchery Production Management Plan (Appendix G of the BCPs) was written with a very specific pathway for addressing the overages. Tonseth said the reason for backup collections in the fall was because of the uncertainty of the spring collections with the understanding that there would be surplus juveniles.

Bill Gale said it is important to note the surplus juveniles were the product of hatchery-origin adults; there are no fewer natural-origin fish on the spawning ground as a result of out-planting to non-anadromous waters. Gale said progeny from excess adult fish that would be collected at Wells Hatchery (surplused at Wells Hatchery) would not have been encouraged to move into the Methow or Okanogan rivers anyway.

Murdoch said it is not a responsible way to deal with overages every year and is glad the changes are being made in the BCP.

Kirk Truscott noted that incremental reductions have been made in the overage each year. Gale said, given low numbers being observed passing over Bonneville Dam so far this year, this could be the year that we wish we would have collected an overage. Tonseth said counts at Priest Rapids Dam (PRD) indicate they will meet their targets.

Tonseth said in the future, if these are discussions that should happen in Committees, Appendix G should be revised, which was intended to allow the process to carry forward without requiring Committee discussion or approval each time. Murdoch said she does support a change to that aspect of the protocol.

Gale asked if there are non-anadromous waters on tribal lands. Tonseth and Truscott confirmed that they did follow through with that but did not find a suitable option before releasing these surplus steelhead.

Tonseth asked Farman whether NMFS could still permit the release of surplus fish that are the result of unexpected overages from in-hatchery effects that are not under the control of the managers, i.e., is it still in the spirit of the permit to release those fish? Murdoch agreed that it is an annual target, but to be under the target in some years and over in some years represents the normal functioning of operations.

Farman said the release of surplus juveniles is problematic because it affects the estimation of “take” in terms of endangered species risk. Farman said programs could come up with a maximum release number with boundaries around that; however, a shift in that number would require re-consulting with NMFS on the number of adults taken for brood. Farman said he was initially a proponent of considering the target release number as an average, for instance over 5 years, to allow for the over- or under-production that occurs due to operations each year. However, the problem with this approach is if there are 3 to 4 years in the 110% range, the operator would be required to produce below mitigation targets to adjust the average downward; that is the origin for developing 110% as an annual limit.

Tonseth supports continuing the improvements on front-end predictions so there are fewer problems on the back-end of production.

Hillman suggested in the future we need to ensure Committee members are aware of surpluses and allow a discussion to be had in Committee meetings.

Tonseth noted that the BCP states the surplus needs to be dealt with at the earliest possible life stage to avoid impacts to densities and other production issues. The discussion needs to be timely and cannot languish for months.

Gale said that regarding Methow steelhead, it should be recognized that use of the term "collection goal" is misleading. The goal refers to the number of natural-origin females spawned; however, the program will over-collect hatchery-origin fish to meet broodstock needs, which is different from some of the other programs. Tonseth agreed that females should be the primary target in the BCPs.

Spring Chinook Surplus

Greg Mackey said the MFH has approximately 8,000 extra spring Chinook salmon eyed-eggs. Mackey said fecundity was high among the 2019 broodstock and reducing the program by 8,000 eyed-eggs will bring the program size to 110% of the target number of juveniles. Mackey said these are the progeny of hatchery-origin female eggs crossed with wild males and that the same wild males were crossed with other fish in production, so those genes would not be lost. Mackey said he inquired if WNFH would accept the surplus eggs but Chris Pasley (U.S. Fish and Wildlife Service [USFWS]) said they are already at target production numbers.

Mackey asked Truscott if they could be used for CCT's 10(j) program at Chief Joseph Hatchery (CJH) as described in step 3 of the Surplus Upper Columbia Juvenile Spring Chinook Management, Methow Sub-basin section of Appendix G of the BCPs. Truscott said he is uncertain whether their permit allows MFH fish to be used for the 10(j) program. The permit stipulates that WNFH fish will be used for the 10(j) program. Murdoch suggested moving 8,000 eyed-eggs from WNFH to the 10(j) program and moving the MFH surplus to WNFH.

Truscott said CJH could accommodate 8,000 extra eyed-eggs but they would have to be at the same developmental stage (measured in temperature units) as the eggs that are currently incubating at CJH. Mackey said one female's eggs will hatch this week and the other two batches will hatch next week. Tonseth said, from WDFW's perspective, destroying eggs is preferable. Once the eggs hatch, they cannot be destroyed and have to be released.

Gale asked how many have already been transferred to the 10(j) program. Truscott said the target of approximately 240,000 has been met, so the proposal to transfer more is problematic. Tonseth said that WNFW can destroy a requisite number of eyed-eggs to accept more from the other program. Gale said WNFW has taken on more coho salmon and is probably at maximum production for steelhead and may not have the capacity to take more eyed-eggs. Gale said he needs to talk to Pasley about whether there is capacity and whether their eggs have hatched yet.

Truscott asked Farman whether receiving eyed-eggs directly from MFH is acceptable, knowing that this is a shift in the terms of the permit. Truscott said currently there are spring Chinook salmon on station at CJH and asked if there are any restrictions to CJH taking 8,000 more than they are permitted to rear. Truscott said CJH will take the eggs if allowable by NMFS.

Farman said he would like to talk to Charlene Hurst about whether the issue of CJH receiving eyed-eggs for the 10(j) program directly from MFH is consistent with the intent of the permit. Mackey said this needs to occur within the next day, prior to fish hatching. Farman asked if there was a written proposal for these steps. Tonseth suggested referring to step number 3 of the Surplus Upper Columbia Juvenile Spring Chinook Management, Methow Sub-basin section Appendix G of the BCPs.

Farman asked what the margins of error are for the egg count. Murdoch said there are a lot of things that can happen between hatch and release. Tonseth said the number of eggs collected has been adjusted for those factors.

Gale said he will call Pasley to confirm whether WNFH can take the excess eyed-eggs. Gale said to do so would affect the PNI results of the 3-population model.

E. Broodstock Collection Protocols Assignments

Tracy Hillman projected the table of assignments for development of content for the 2020 BCPs and reviewed the tasks and timing of necessary discussions.

Bill Gale asked what the timeline is for reviewing contributions and agreeing to what will be written in the BCPs. Hillman said assignments should be completed during the November meeting. Authors will then commence drafting sections of the BCPs. Members will review draft sections during December, January, and February.

Greg Mackey agreed to prepare alternative spawning recommendations for the November meeting, including testing new methods in certain programs. Gale suggested testing the use of the alternative broodstock methods in the Methow spring Chinook salmon program first. Mike Tonseth said there may not be enough spread in ages because spring Chinook salmon tend to return largely at the same age. Tonseth suggested the Carlton program (Methow/Okanogan summer Chinook salmon raised at Carlton Acclimation Pond) for testing the methods with a multiple age-class mix. Mackey said Douglas PUD is interested in trying the method with the Wells summer Chinook salmon, also.

Kirk Truscott asked how the broodstock would be collected. Mackey said broodstock are collected in the usual way, i.e., take healthy fish and attempt to match larger males with smaller females. Mackey said the selection for larger males is not made during collection. Gale said because there is no way to test the success of the method, he suggests trying it with any stock to test the feasibility of implementation, but not necessarily to test for biological effects. Tonseth said the way the implementation would work is that the largest males would be selected when they are ripe and smaller males may be selected just because they are ripe on the given day. Mackey agreed that feasibility of the implementation should be tested.

Mackey agreed that it is probably not possible to test the biological effects and it should be implemented on faith that it is the best method for the resource. Tonseth noted that the literature suggests this could be a best management practice. Gale reminded members that the Hankin method was modeled but has not yet been implemented.[1] Todd Pearsons asked if the test is to look for an increase in age at maturity. Gale said the decision is to use best management practices.

Hillman said the most recent edition of Tom Quinn's 2018 salmon ecology book[2] focuses on four primary reasons for change in age at maturity and references the original work by Ricker, which discusses the balance between selecting for earlier maturation versus forcing fish to spend another year in the ocean and subjecting them to another year of harvest. Gale said he supports using the knowledge of what fish do in nature to improve hatchery spawning practices and that perhaps the outcomes will not be to produce all older fish but broaden the age distribution, which may also benefit the stock.

Hillman summarized the BCP discussion tasks and asked if there were other topics that should be discussed next month to avoid conflicts later.

Tonseth said parts of the BCP could be reviewed early. Tonseth suggested that appendices be distributed for various authors to work on prior to review of the complete plan in February. Suggested co-authors and notes on production status for each appendix are summarized in Table 1.

Table 1
2020 Broodstock Collection Protocols Assignments

Appendix	Title	Assigned Parties	Notes
A	2019 BY Biological Assumptions for UCR Spring, Summer, and Fall Chinook and 2020 BY Summer Steelhead Hatchery Programs	WDFW and PUDs	
B	Current Brood Year Juvenile Production Targets, Marking Methods, Release Locations	All	
C	Return Year Adult Management Plans	WDFW lead	Contingent on run forecast available in Jan/Feb 2020
D	Site Specific Trapping Operation Plans	PUDs and M&E staff YN to review	Identify plans and ensure they are still accurate
E	Columbia River TAC Forecast	WDFW	Forecast available in late Dec 2019/early Jan 2020
F	Annual Chelan, Douglas, and Grant County PUD M&E Implementation Plans	PUDs	Provide links
G	DRAFT Hatchery Production Management Plan	All	
H	DRAFT Preferred Alternative for 2020 BY and Beyond, Methow Sub-basin Conservation Steelhead Programs	Revisit after completion of 2019/2020 steelhead return	Pending discussion by Joint Fisheries Parties; concern about acquiring broodstock in the spring
I	Program Specific Rearing and Release Descriptions	PUDs and M&E staff	Staged release at PRH to be addressed
J	2019 BY Spring and Summer Chinook Disease Management Plans	CPUD M&E staff and WDFW veterinarian (Megan Finley)	

K	2019 YN Coho Broodstock Collection Plans	YN	
General	Species-Specific Run Forecasts	WDFW	

Tonseth will break out the appendices and send those to Larissa Rohrbach for distribution. Tonseth requested that all edits be submitted to him by the December meeting and for members to identify any additional issues that require further discussion during the December meeting. Tonseth said some topics will require waiting until completed returns are observed in October.

F. National Marine Fisheries Service Consultation Update

Brett Farman said there is no new update from last month. Representatives from the PUDs confirmed that the recently finalized permits have been signed or have been submitted within the PUDs for signature.

Tracy Hillman asked what the next steps are. Mike Tonseth said the next permit is the Wenatchee Spring Chinook permit, which is due in 2026. Truscott said it depends on the results of the next 5-year status review (due in 2021). Hillman asked members to identify when discussions should start on developing the Hatchery and Genetic Management Plans. Tonseth said recalculation will occur in 2023. Farman suggested starting discussions in 2023.

III. PRCC HSC

A. Approve the September 18, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the September 18, 2019 meeting minutes as revised.

Brett Farman said he will not be able to attend the November meeting and so would send along his updates via email, or inquire whether his alternate, Charlene Hurst, could attend.

B. Recap Wenatchee Spring Chinook Salmon Life-Cycle Model and Next Steps for White River

Tracy Hillman said the presentation by Jeff Jorgensen to the PRCC was similar to a presentation to the Regional Technical Team (RTT), with some updates and specificity for the hatchery programs. PRCC Facilitatory Denny Rohr told Hillman that the PRCC is still working to determine the next steps for the HSC.

Keely Murdoch stated that the PRCC has not yet met this month. Murdoch summarized the overall problem for the PRCC HSC, that, in her opinion, the Lake Wenatchee survival proposal that was submitted by WDFW was missing a step to collect data that could feed into the life-cycle model (LCM), and what was missing was identification of the questions the LCM would be asked to answer. Murdoch said the PRCC was stuck on whether to issue an RFP for additional data collection because members could not decide what data should be collected. Murdoch said she hopes the path forward is the PRCC can come up with a list of questions they would like the LCM to address. Jorgensen can then confirm what additional data are needed to fill these data gaps, and the PRCC could move forward with a proposal.

Todd Pearsons was thinking that Jorgensen would try to answer the questions that were prepared by the PRCC HSC, but time ran out and the majority of them were not addressed. Murdoch said she thought many of them were addressed in the presentation. Pearsons noted that there will be three talks about the topics in question at the upcoming Upper Columbia Science Conference that may inform this process: a talk by Matt Polacek (WDFW) on predator assemblage in Lake Wenatchee, one by Carlos Polivka (USFWS) on effects of non-lethal predation risk in Lake Wenatchee, and one by David Beachamp (University of Washington) on rearing and foraging behavior using stable isotope analysis in Lake Wenatchee. In addition, Dan Rawding is presenting an Upper Columbia spring Chinook salmon life-cycle survival model using passive integrated transponder (PIT) tags. Jorgenson referred to this other model during his presentation. Pearsons said it looks like there is a fair amount of work that is ongoing or has already been done in Lake Wenatchee.

Mike Tonseth said WDFW's predator assemblage analysis was done as part of the original Lake Wenatchee study proposal and is a replication of Thompson and Tufts' work done in the 1960s to confirm which predators are eating which prey.

Hillman summarized that the HSC will wait for direction from the PRCC per feedback from Rohr.

IV. Administration

A. Next Meetings

Larissa Rohrbach reminded the HCP HCs that Douglas PUD's 2018 M&E Report is currently available for a 60-day review, with comments due to Greg Mackey by November 15, 2019.

Todd Pearsons asked whether the group had decided that annual reports should be limited to a 30-day review to streamline the review periods. PUDs intended to spread the reviews over the year. Kirk Truscott said that he generally does not need the 60-day review but sometimes needs the 60-day period to find time to work on it. Bill Gale said 60 days is useful so other staff can review. Tracy Hillman reviewed protocols and confirmed that it states at least 30 days unless decided otherwise. Gale said his preference is that if 60 days can be given then to do so. Mike Tonseth said implementation plans were already shifted to accommodate contracting. Pearsons said he will be sending the PRH report soon so there will be some overlap in the review period with the Methow program report.

The next HCP-HCs and PRCC HSC meetings are November 20, 2019, December 18, 2019, and January 15, 2020, at Grant PUD in Wenatchee, Washington.

Review of Hatchery Broodstock and Mating Practices for Conservation Programs

Greg Mackey

Douglas PUD

October 14, 2019

Introduction

The Upper Columbia includes several conservation hatchery programs for spring Chinook and summer steelhead in the Wenatchee and Methow basins. The premise of a conservation hatchery program is to rebuild depleted stocks while conserving genetic diversity and minimizing negative ecological and genetic impacts on wild populations (Fisch et al. 2014). Inevitably, hatcheries induce artificial selection on the fish held and reared within (Christie et al, 2012; Neff et al. 2011). To counter artificial selection, conservation hatchery operations are typically designed to induce as little artificial selection as possible. The extent to which this is implemented and is successful is clearly debatable and likely varies widely across species, programs, and hatchery practices at different facilities (see Auld et al. 2019; Fraser 2008). Artificial rearing emancipates fish from natural selection while in the hatchery setting, which may reduce their fitness in the wild. While this review of mating strategies is broad in nature, the particulars focus on Methow basin spring Chinook, but the principles can be applied to other conservation hatchery programs.

Background

Selection of broodstock is the first opportunity where artificial selection may affect fish in the hatchery setting. The age of the fish, with size as a proxy, have been commonly used to choose which fish are retained and mated in the hatchery, with particular focus on incorporation rates of jacks. The age-3 proportion of returning adults for the Methow basin spring Chinook population has averaged 0.0729 from 2006 through 2018 (Figure 1). This proportion may be used to inform the rate at which age-3 males could be incorporated into broodstock (e.g., use 7% age 3 males in broodstock), while the proportion used in spawning may be further modified by an estimate of their reproductive success in the wild relative to larger males (Olson et al. 2004). For example, Berejekian et al. (2010) estimated that Chinook salmon jacks sired 20% of the offspring in a controlled study where the number of males was held constant and Schroder et al. (2012) found jacks sired 3% of the offspring in a similar study. Thus, using the 20% figure, for example, could result in a program where:

$$7\% * 20\% = 1.4\% \text{ age 3 male contribution rate in hatchery program}$$

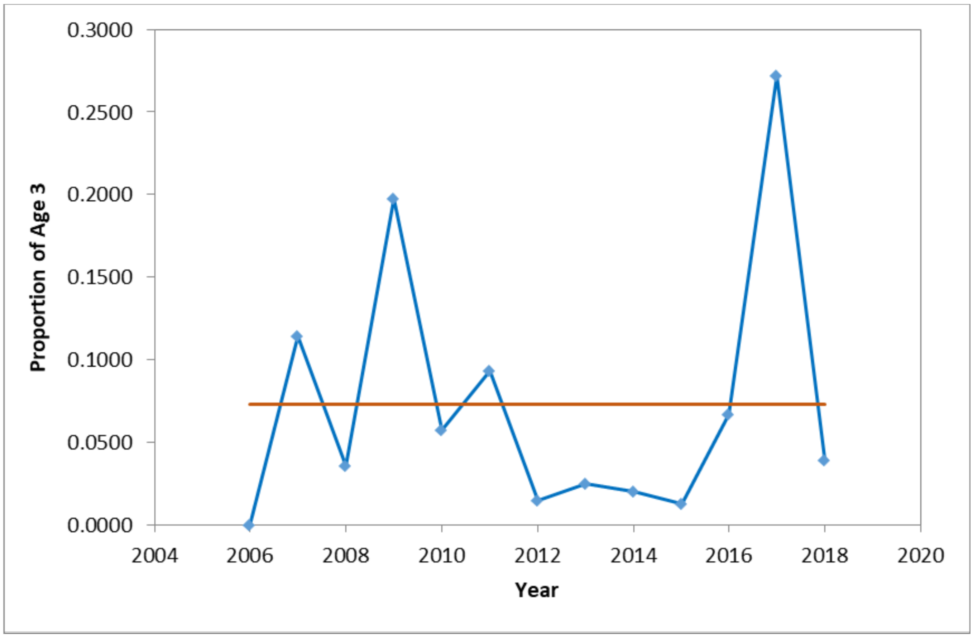

Figure 1. Proportion of Age 3 spring Chinook sampled at Wells Dam (mean = 0.0729, orange line)

Fisheries can select for younger age at maturity and such selection can be exacerbated by hatchery propagation due to increased harvest rates on populations supplemented by hatchery programs, gear directed to capture older, larger fish, and mixed stock fisheries (Quinn 2005b; Hankin et al. 2009). This phenomenon may affect Methow spring Chinook, where losses of wild Methow basin spring Chinook as estimated from PIT tags between Bonneville Dam and McNary Dam have ranged from 0.00-0.40 for 2-ocean fish and 0.00-0.29 for 3-ocean fish, while 1-ocean fish are not harvested (Figure 2).

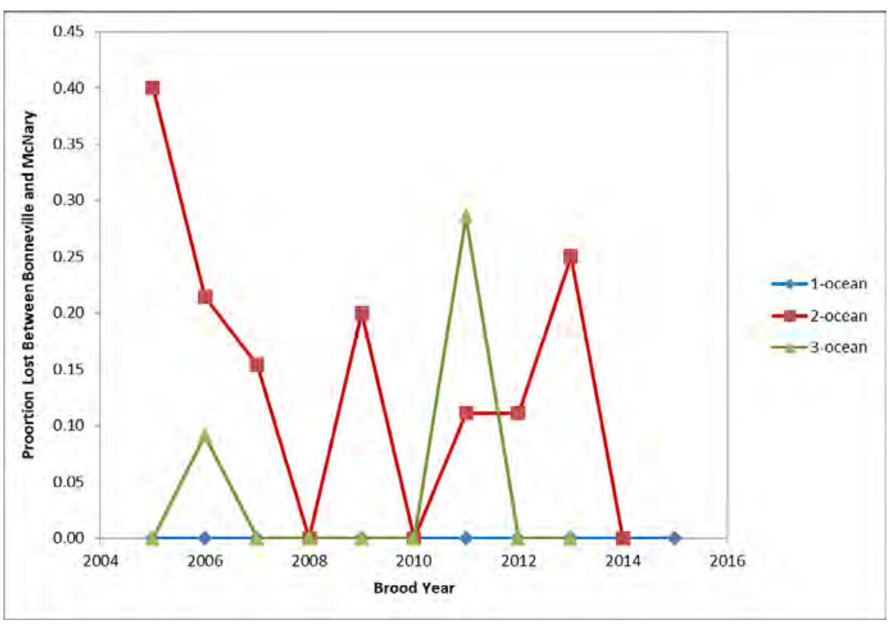

Figure 2. Losses of wild Methow basin spring Chinook between Bonneville Dam and McNary Dam by brood year

Mating systems of salmonids are extremely complex in nature, as exemplified by Seamons et al. (2004), where in a small steelhead population, matings ranged from monogamy to polygynandry networks consisting of up to 16 fish (Figure 3). Many potential parents had no offpspring detected: males = 43% and females = 23%. The point of this is that natural mating systems are complex and include multiple mating systems and extensive competition for mates and opportunity to fertilize eggs. Natural mating systems bear little resemblance to hatchery spawning protocols (Figure 4).

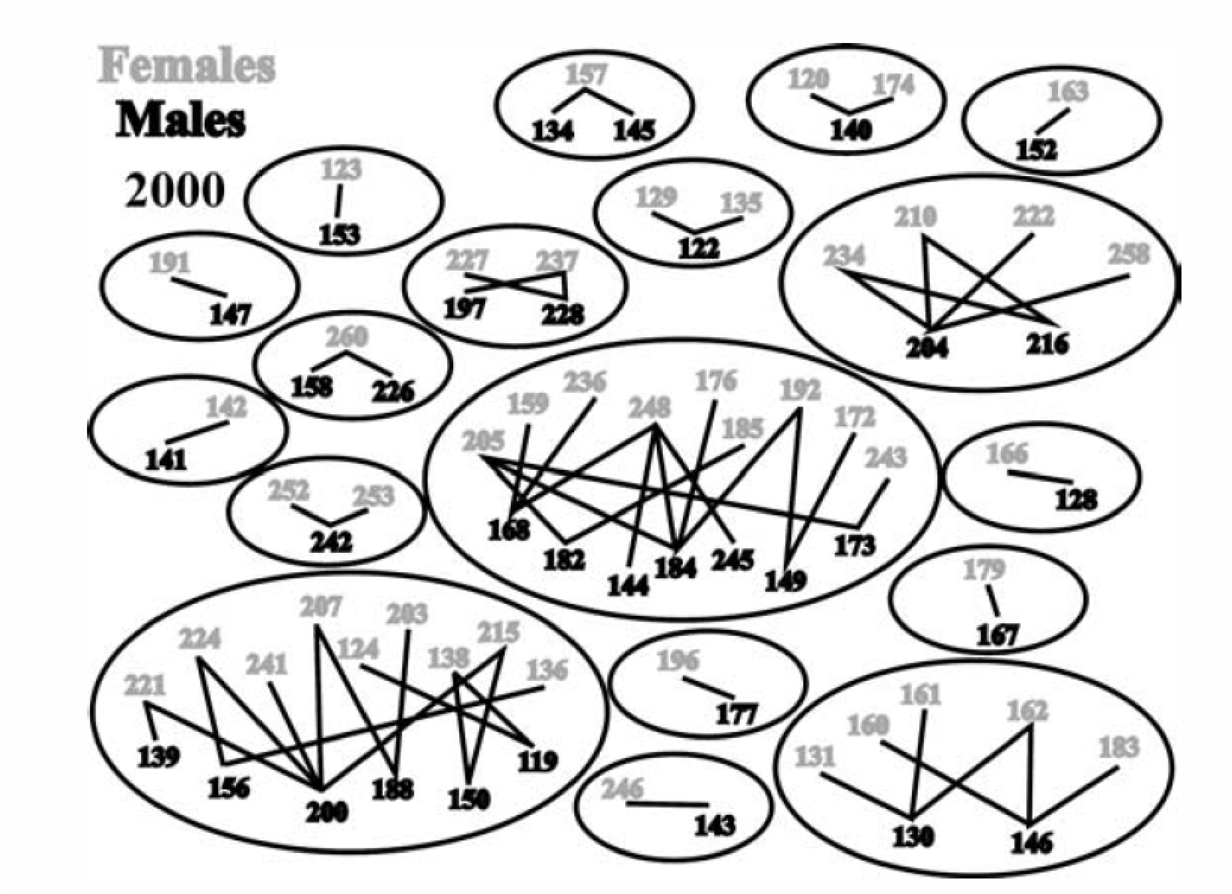

Figure 3. Inferred mating patterns of steelhead in Snow Creek from BY 2000. Each oval encompasses the individual parents (shown as identification numbers) in a mating group inferred from an extended half-sibling family of offspring. Lines connect males (solid black numbers) and females (gray numbers) with their inferred mate(s). Four types of mating were apparent: monogamy, polygyny, polyandry and polygynandry (from Seamons et al., 2004).

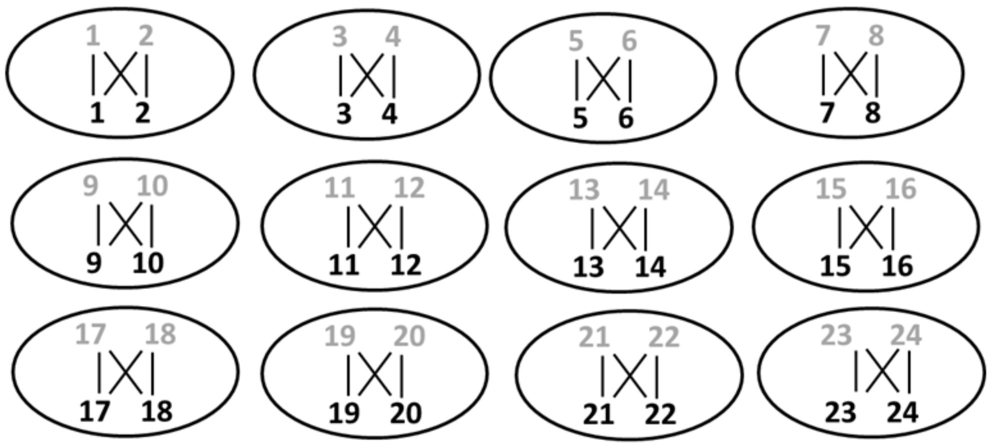

Figure 4. Typical 2x2 matrix mating pattern in a hatchery.

Population size, program size, and population history (e.g., bottlenecks) all may affect a supplemented population. However, the perception these factors may invoke does not necessarily predict the status of the population. The average homozygosity in the Methow Hatchery's Twisp Spring Chinook 2017 brood sample was lower than in any Spring/ Summer population samples in the Snake River baseline (Figure 5; Young et al., 2019). This suggests that despite obvious opportunity for genetic bottlenecks and a small hatchery program, to this point the integrated hatchery and wild populations are genetically robust compared to other similar populations. This analysis was originally performed to preliminarily explore the relatedness of parent in a group of juveniles displaying deformed caudal peduncle morphology. This result should be interpreted cautiously because it is from one sample of 50 deformed offspring from the Twisp River program. The analysis, preliminarily, did not suggest that the parentage of the deformed fish was from only a select group of parents, which might indicate a familial genetic link. Nevertheless, the homozygosity result is rather surprising.

Phenotype may provide further insight into the status of a population. The length of age 4 wild fish females appears to be constant over time, but fecundity may be declining. Wild and hatchery females at age 4 show no difference in fork length (Figure 6). Fecundity of Wells Hatchery Summer Chinook broodstock may also be declining (Figure 7). Declining fecundity in a wild population is of concern and there is little guidance as to how this may be countered, but see Hankin et al. 2009.

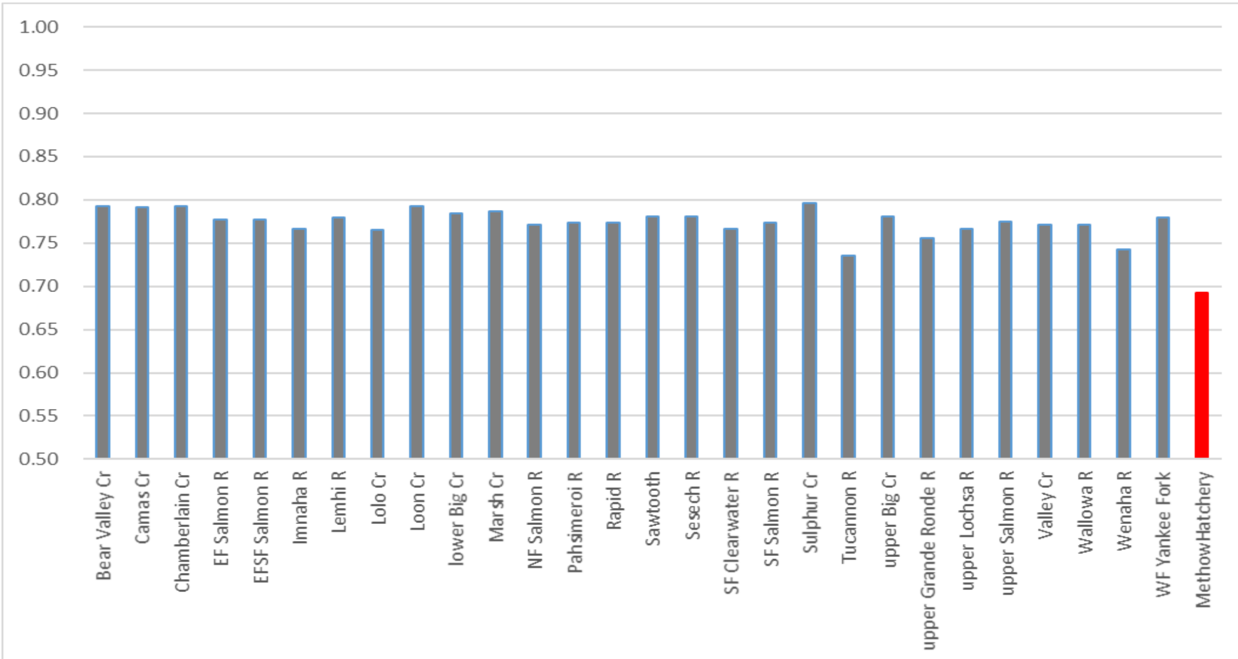

Figure 5. Average homozygosity of spring Chinook in the Snake River basin and Twisp River, Methow Basin (from Young et al., 2019).

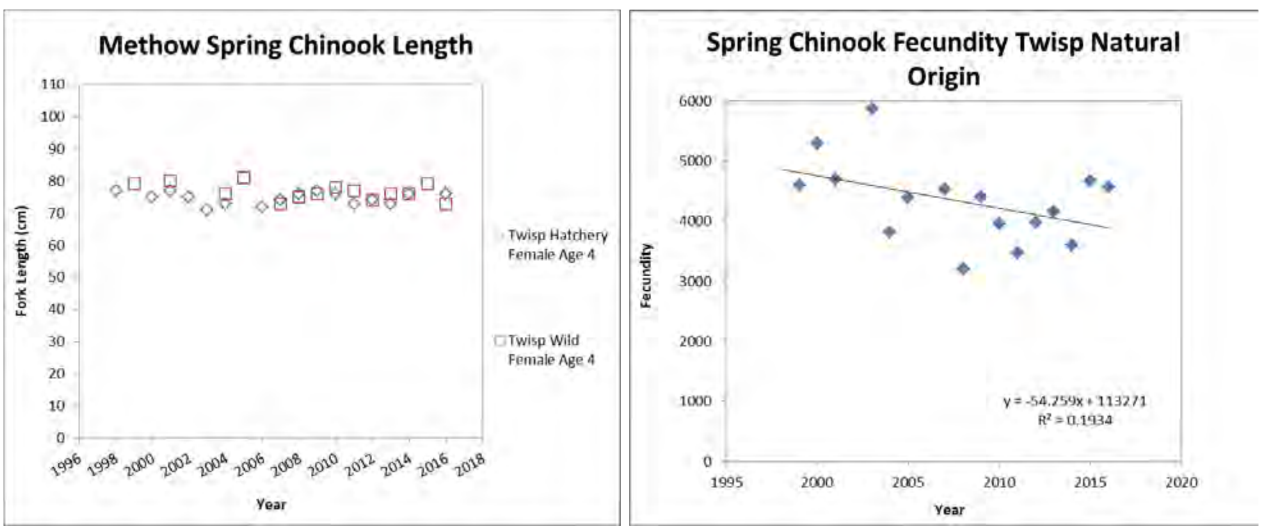

Figure 6. Mean annual fork length of hatchery and wild Twisp spring Chinook females (left) and fecundity of wild females (right).

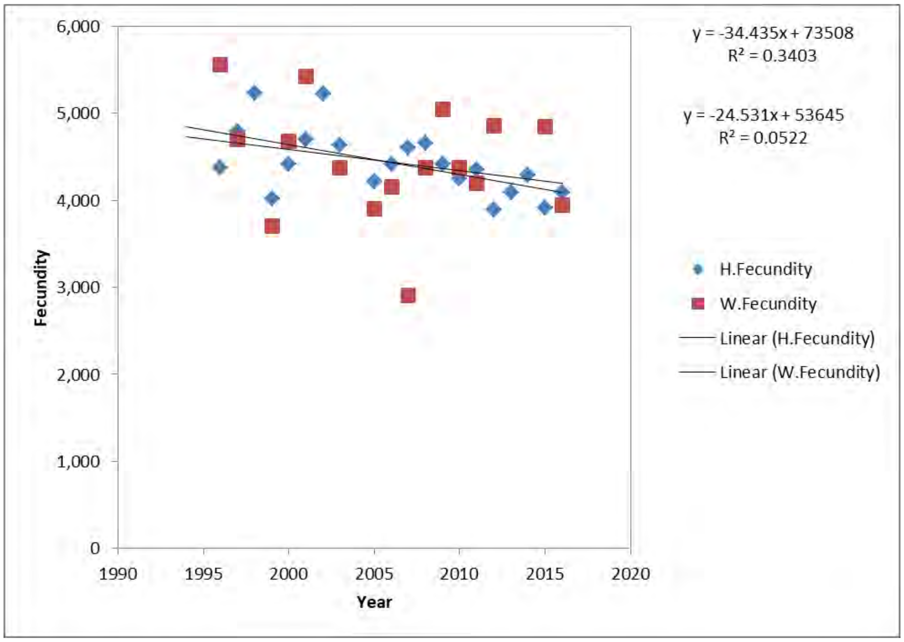

Figure 7. Mean annual fecundity of hatchery and wild female Summer Chinook at Wells Hatchery.

Strategies for Broodstock Management

Broodstock collection and spawning are the first steps in the sequence of hatchery program actions. The program specifications as to which fish to capture and retain for broodstock and how they are mated will have a profound effect on the resulting hatchery population, and this population will subsequently interact with the wild population. Therefore, it is important to operate the program in a manner to achieve the goals of the program. In general, there are two philosophies for managing broodstock and mating designs in conservation programs: 1) Attempting to minimize genetic divergence caused by the hatchery program by emulating and preserving the genetic diversity of the population (e.g., HSRG 2004; Campton 2004); and 2) Attempting to emulate the selective regime in the wild to preserve the fitness of the population and minimize effects of domestication (e.g., Hankin et al. 2009; Quinn 2005a). There are several aspects of broodstock collection, mating and spawning for which a variety of authors have recommended certain strategies:

Genetically Benign Approach:

1. Incorporation of sufficient numbers of natural-origin adults into the broodstock each year to overcome the potential effects of random genetic drift, domestication and divergent natural selection in the two environments.
2. Protocols for trapping and spawning adults such that the means and variances of phenotypic characters related to fitness (e.g., run timing) equal those of the parental natural population
3. Efforts made to minimize artificial selection and other domestication effects in the hatchery (behavioral, epigenetic, gene-environment interaction).
4. Broodstock collection

   a. Random selection of parents from the pool of available adults with respect to age, size, and other life history characteristics (Campton 2004; HSRG 2004)
      i. Jacks should be included (Campton 2004; HSRG 2004)
      ii. Cull to equalize family size to optimize effective population size (HSRG 2004)
5. Mating Scheme
   a. Spawn randomly with respect to age, size, and other life history characteristics

<u>Emulate Natural Processes Approach:</u>

1. Hankin (2009) – modeled spawning design to counter selection in the hatchery for younger age at maturity.
   a. Idea is to counter artificial selection in the hatchery for younger age at maturity (Larsen et al., 2019) and to help counter selection by fisheries for younger age at maturity.
   b. Attempts to emulate the spawning structure/mate choice that would occur in the wild to maintain fitness in the population.
   c. Note that Larsen et al. (2019) found that integrated hatchery program broodstock resulted in higher rate of early maturation (progeny of wild parent mature early compared to hatchery parents, even after one generation in the hatchery environment).
2. Quinn (2005a) – Breeding schemes where each adult is given equal opportunity to contribute to reproduction, and milt from two or more males is never mixed, does not remotely resemble natural mating systems.
   a. The key processes in hatcheries occur during broodstock collection and during mate choice and gamete collection.

<u>Other Aspects of Broodstock Management:</u>

1. Minimize kinship
      i. In captive breeding programs this is the best way to retain genetic diversity (Ivy and Lacy, 2012)
      ii. Our programs are not captive breeding programs, but these principles may still apply.
         1. Retrospective analysis of relatedness in programs is possible in some cases. This could help us identify if there are potential improvements or if the program is doing a good job of not performing matings of close relatives.
2. Mating Schemes
   a. Random Pairwise 1:1
      i. All adults have equal opportunity to reproduce
   b. Overlap Pairwise
      i. Backup male used
      ii. Sperm competition can still occur even 45 s after first fertilization.
   c. Pooled
      i. Sperm competition
      ii. Loss of control over mating scheme – not recommended by anyone.
   d. Pooled Matrix

        i. Multiple females' eggs mixed and separate into aliquots. Separate males fertilize each aliquot.
        ii. Greater potential for disease transmission
        iii. Cannot track family groups for disease management or performance analysis
    e. Nested
        i. For skewed sex ratio 1:2 or more
        ii. Recommendation is to collect more fish so the less abundant sex meets minimum broodstock needs and excess of the abundant sex are discarded.
    f. Factorial (Matrix) (Busack and Knudsen, 2007)
        i. 2x2, 3x3, 4x4 etc.
        ii. Maximizes number of family groups and genotypic diversity
        iii. Maximizes effective number of breeders in the hatchery

<u>Current Conditions – Methow Hatchery Programs:</u>

The Methow Hatchery currently follows these protocols for broodstock collection and mating:

1. Broodstock collection is (somewhat) random
    a. Brood is attempted to be collected across the entire run timing, but the realities of trapping a small population and to minimize the number of fish trapped and handled tend to front load the trapping to ensure enough brood are captured.
    b. Injured or sick fish may not be retained to improve the chances that the fish will survive to spawning in the hatchery.
    c. Jacks are not retained (except in 2019 the Broodstock Protocols included an exception to retain jacks if wild males were in short supply).
2. Mating follows a 2x2 matrix with males used as backup reciprocally.
    a. The programs are small and therefore, there are relatively few fish to spawn per week. This limits the range of possibilities for matrix spawning.
    b. Fish to be mated are chosen at random by staff, but it is likely they are not randomly chosen in terms of phenotypic traits (Mclean et al. 2005).
3. Culling
    a. Families are not culled to equalize family size.
    b. Culling may be performed to control BKD, but this has rarely been done in recent years. Instead, families are held in quarantine to see if clinical signs of disease manifest. If not, the fish are carried through to production.

<u>Possible Path Forward – Methow Hatchery Programs:</u>

The Methow Hatchery could make the following adjustments to the protocols for broodstock collection and mating:

1. Broodstock collection
    a. Brood collection to be random (to the best of our abilities).
    b. Jacks included in collection at a pre-determined rate; (e.g., up to 7%; see below).
2. Mating
    a. Continue to use factorial mating protocol with backup male

   i. Ensure enough time has passed between primary and backup fertilization to prevent sperm competition (>>45s).
   ii. Jacks to fertilize only a partial aliquot of each female mate's eggs (e.g., 7% of the females will have up to 20% of their eggs fertilized by jacks [results in about 1.4% of all eggs being fertilized by jacks]; to be determined)

b. To the extent possible, follow the protocol in Hankin et al. (2009) where larger males are preferentially mated with smaller females to select for older age at maturity to counteract effects of hatchery propagation and fisheries.

October 16th, 2019

Rock Island and Rocky Reach HCP Hatchery Committees
Statement of Agreement
Improvement Feasibility at Eastbank Hatchery for Wenatchee summer Chinook
FINAL
(Chelan PUD, NMFS, USFWS, WDFW, YN, and CCT approved on February 17, 2016)

Statement

The Rock Island and Rocky Reach Habitat Conservation Plans' (HCP) Hatchery Committees (HC) agree that Chelan PUD will proceed with a feasibility for design of a chilled, partial water reuse aquaculture system at Eastbank Hatchery for Wenatchee summer Chinook, to enable Chelan PUD to meet phosphorus discharge limits under the Wenatchee River Total Maximum Daily Load (TMDL) for dissolved oxygen and pH.

Background

On March 7, 2012 the Washington Department of Ecology issued an *Addendum to the Wenatchee River Watershed Dissolved Oxygen and pH TMDL, WRIA 45.* This Addendum acknowledged that the Dryden Acclimation Pond was not assigned a waste load allocation when the initial TMDL was published in 2010 and sought to remedy the oversight. As such, the Dryden Acclimation Pond received a waste load allocation of 9.2 micrograms/liter of total phosphorus, during facility operation. Subsequently, in July 2012, Chelan PUD committed to evaluating multiple activities (*Chelan PUD- Dryden TMDL Compliance, July 18, 2012*) to ensure that Chelan can meet hatchery production levels at Dryden Acclimation Pond while operating in compliance with the TMDL. As a result, Chelan completed a robust feasibility analysis and concluded that the most effective and risk minimizing approach to meeting phosphorous discharge limits is to rear Wenatchee summer Chinook to a smaller size (anticipated to be 18 fpp). This would be accomplished by constructing a new chilled partial water reuse system at Eastbank Hatchery utilizing circular ponds as a successfully demonstrated rearing practice, prior to transfer to the Dryden Acclimation Pond for final spring acclimation.

Introduction

- March 7, 2012 – Ecology issues Addendum to Wenatchee River TMDL for DO and pH, allocating 9.2 micrograms/liter of waste load to the Dryden Acclimation Facility
- July 12, 2012 – Chelan proposes to evaluate five actions to determine compliance with the TMDL

Preliminary Actions

1. Measure baseline phosphorus levels in Wenatchee River and Dryden facility (Chelan PUD) before, during, and after fish on station
2. Conduct low phosphorus feed trial at Dryden (Grant PUD & Chelan PUD)
3. Benchmark Chelan Falls and Leavenworth circulars (Chelan PUD & USFWS)
4. Evaluate size of smolts released-use physiological data and PIT tag data to empirically test different smolt sizes (NOAA-Beckman and Larsen & Chelan PUD)
5. Evaluate the number of fish released and effects on phosphorus levels (Chelan PUD)

Results

- February 17, 2016 – Final SOA to conduct feasibility for a chilled partial water reuse facility with round pond technology at Eastbank Hatchery.

Secondary Actions

- Negotiation with Ecology
  - Eliminated background phosphorous loading
  - Clarified collection metrics
- Modified feeding practices
  - Hand feeding
  - Strengthened BMPs
  - Low phosphorous feed
- Rearing Wenatchee summer Chinook to a smaller size
  - 18 FPP target (16 FPP +/- actual)

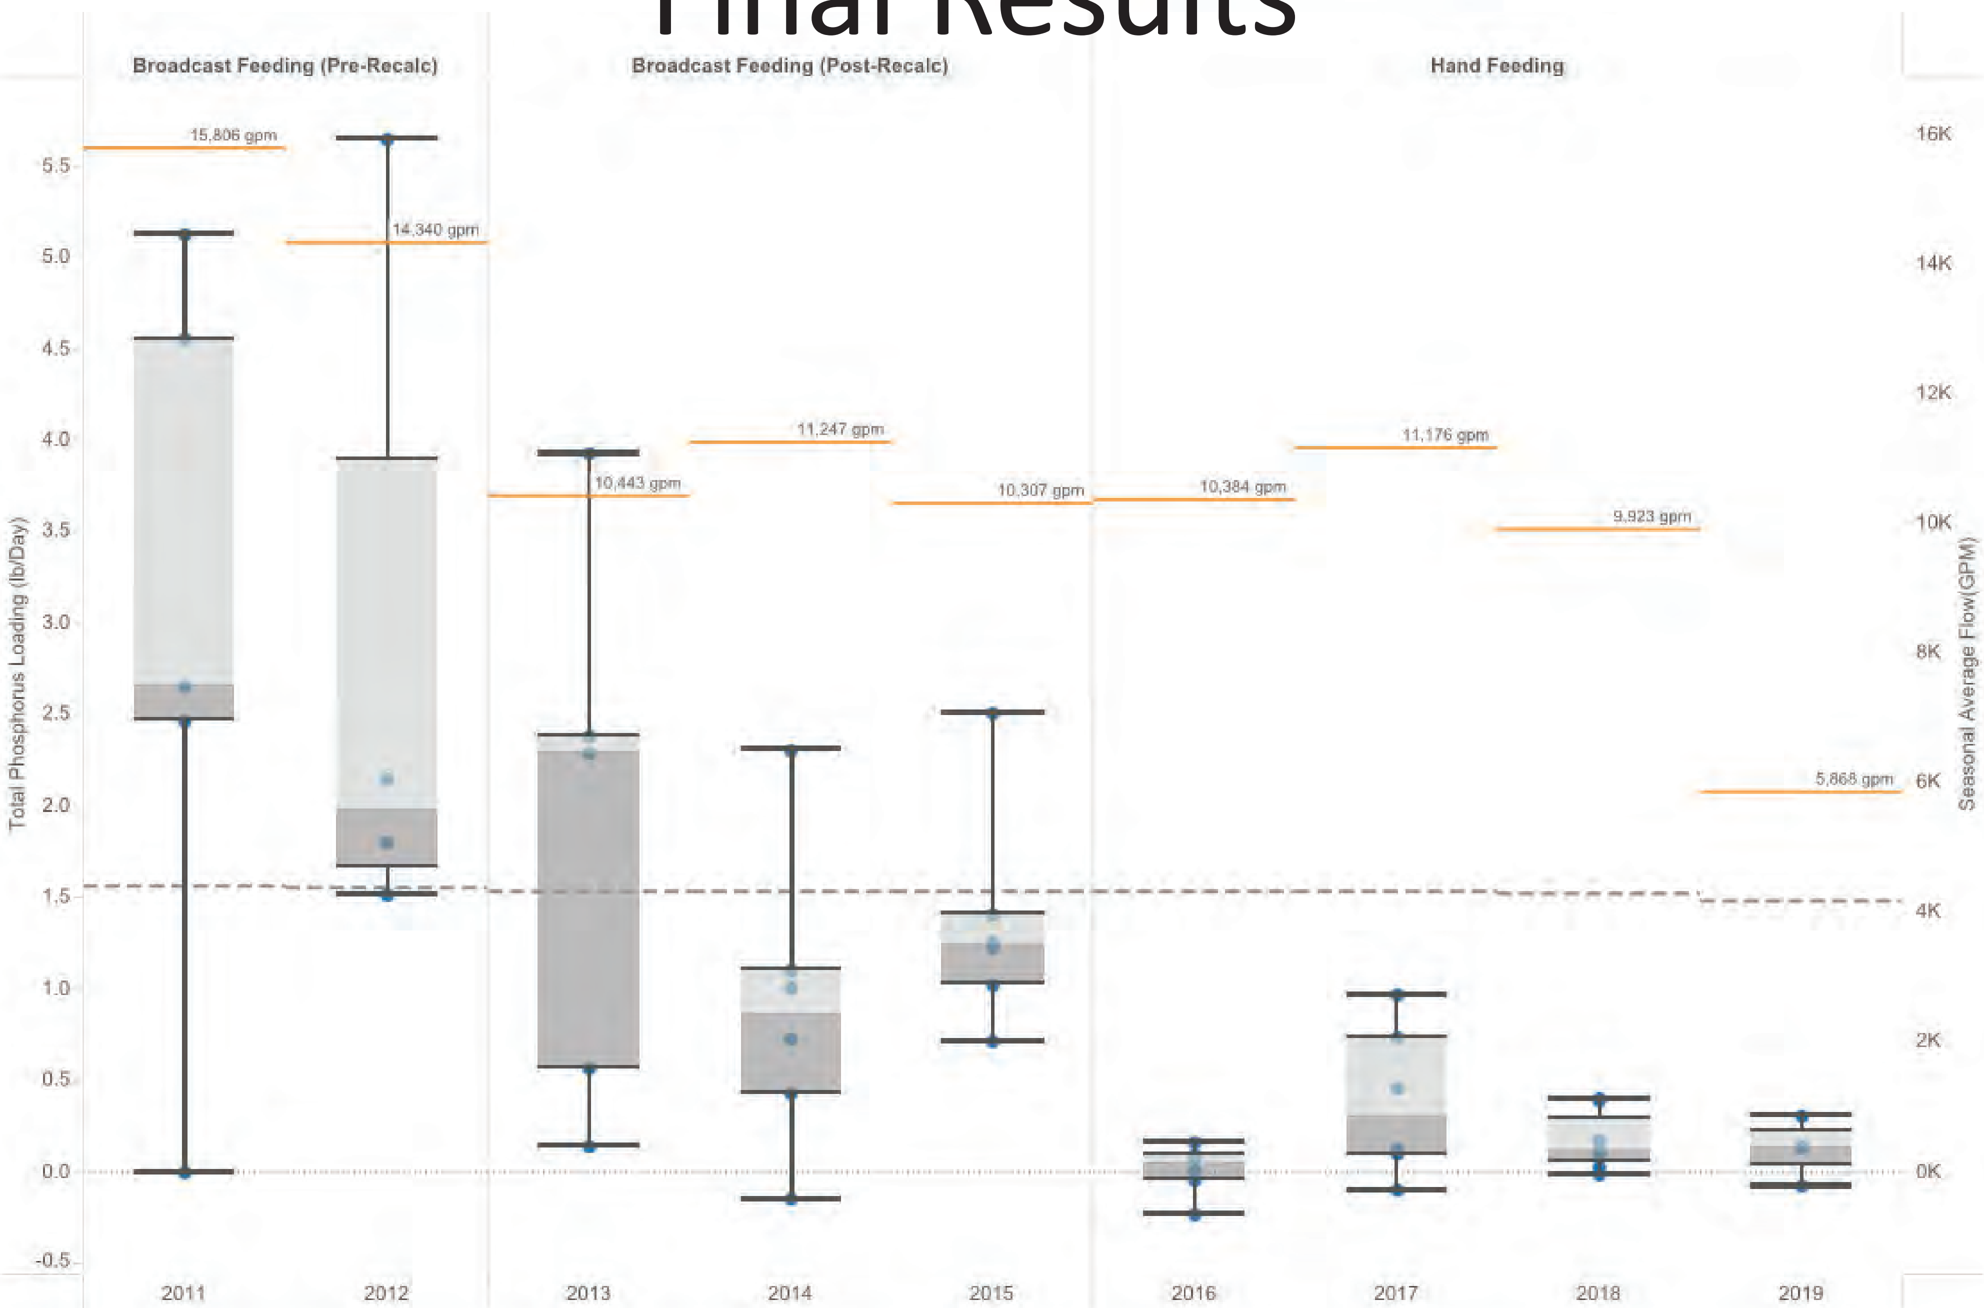
Attachment C

Final Results



Note: Dots represent the average net pond loading of each of the individual sampling events (grab, or continuous) during their respective season. Flow data represents the seasonal average. Estimated Seasonal TMDL's are presented in each year with a dashed line.

Summary

- Continued negotiation with Ecology results in
  - Ecology refines the their allocation table to remove ambiguity
  - Ecology allows the District to eliminate background phosphorous from the Dryden Pond's total phosphorus effluent results

Summary

TMDL Addendum Limits Table – March 07, 2012

Dryden Q	Conc	Load
cfs	ug/L	g/d
33	9.2	743
17	16.1	670
8	32.0	626
4	62.3	610
2	122.8	601
1	243.6	596

Facility Specific Cover Page Limits Table – November 01, 2018

Effluent Limitations

Flow, cfs [1]	Daily Maximum Net, Total Phosphorus, grams/day [2]
>17.0 to 33.0	743
>8.0 to ≤17.0	670
>4.0 to ≤8.0	626
>2.0 to ≤4.0	610
>1.0 to ≤2.0	601

[1] Flow sampling at rearing facility intake

[2] Phosphorus sampling at rearing facility effluent prior to mixing with the receiving waters

Summary

- Dryden Pond meets Ecology’s TMDL without the need for RAS development at Eastbank Hatchery
  - An additional benefit realized through operational optimization is a reduction in water consumption by adhering to accepted industry standards for Flow Indices (FI)
- The District installed automated water samplers to collect required samples weekly

Broodstock Calculation

Basic Broodstock Calculation

Number of Females Collected X Pre-Spawn Survival X BKD Culling Survival X Fecundity X Egg to Release Survival = Smolts

Number of Females Collected → Assume 1:1 Sex Ratio → + Number of Males Collected = Total Broodstock

Broodstock Calculation

Example

55 females X 0.979 pre-spawn survival X 0.814 cull survival X 3,702 fecundity X 0.837 egg to release survival = 135,000 smolts

Assume 1:1 Sex Ratio → + 55 males = 110 broodstock

Attachment D

Broodstock Calculation

Example

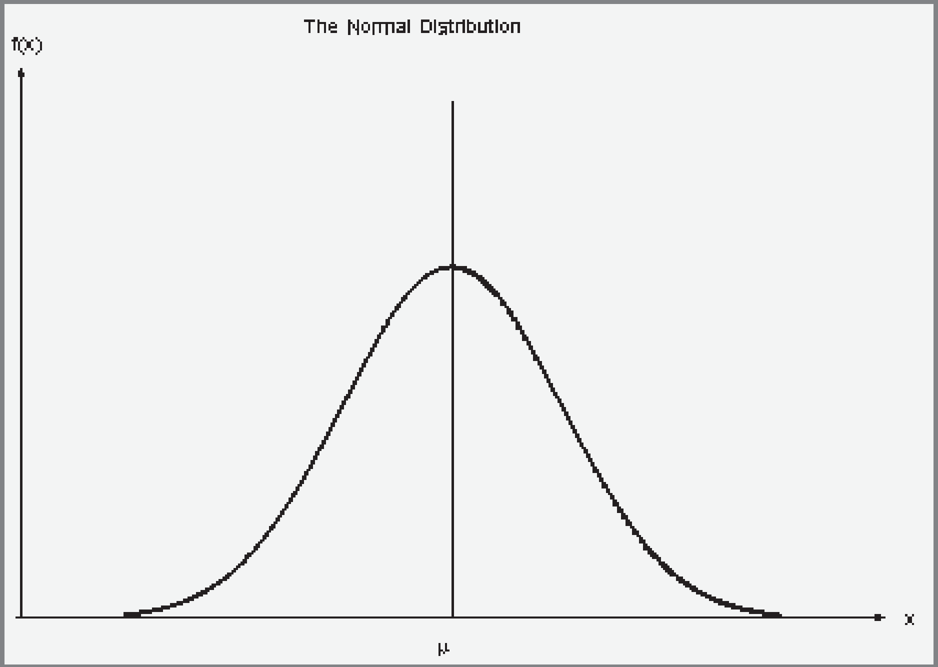
55 females X 0.979 pre-spawn survival (sd = 0.09) X 0.814 cull survival (sd = 0.133) X 3,702 fecundity (sd = 201) X 0.837 egg to release survival (sd = 0.037) = 135,000 smolts

Assume 1:1 Sex Ratio → + 55 males = 110 broodstock

Attachment D

Normal Distribution

50 % above the mean
50 % below the mean



Broodstock Calculation

How often would a parameter be outside of the +/- 10% range?

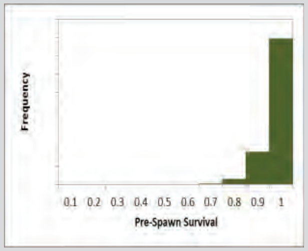
55 females	X	0.979 pre-spawn survival sd = 0.09	X	0.814 cull survival sd = 0.133	X	3,702 fecundity sd = 201	X	0.837 egg to release survival sd = 0.037	=	135,000 smolts
		16.0 %		51.5 %		6.1 %		2.5 %		

Attachment D

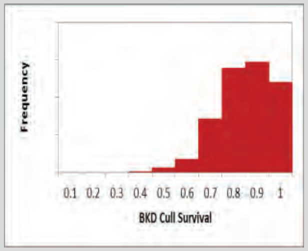
Broodstock Calculation

Example of Uncertainty

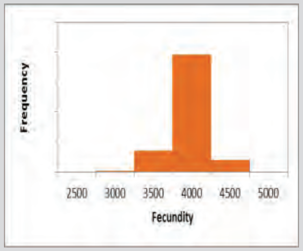
55 females X



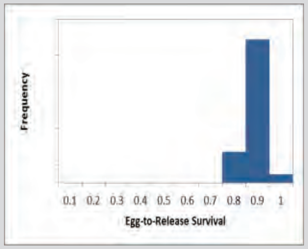
X



X



X



= 135,000 smolts +/- 95% CI

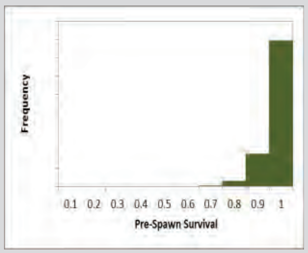
Assume 1:1 Sex Ratio

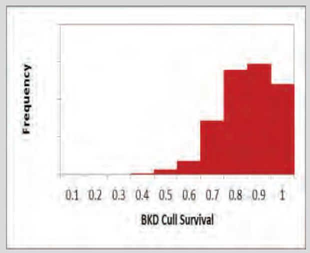
+ 55 males = 110 broodstock

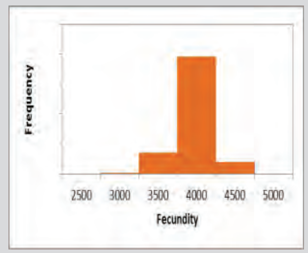
Attachment D

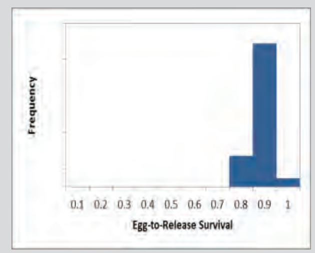
Broodstock Calculation

We can model this









Random Draw

How many females? X Pre-Spawn Survival X BKD Culling Survival X Fecundity X Egg to Release Survival = 135,000 smolts +/- 95% CI

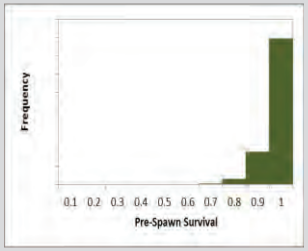
Attachment D

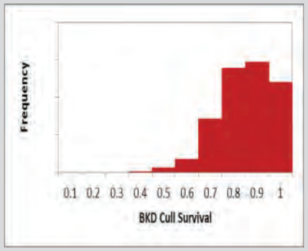
Repeat and Test Critical Values for Varying Numbers of Broodstock

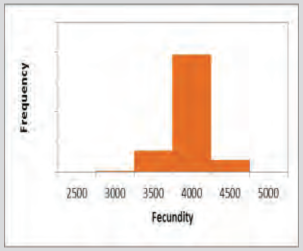
Target Production Value

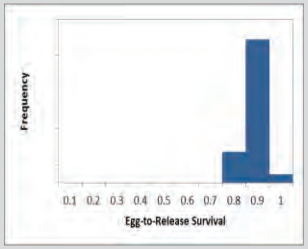
+10 % Production Value

Probability of Meeting Target and Below 110%









Random Draw

How many females? X Pre-Spawn Survival X BKD Culling Survival X Fecundity X Egg to Release Survival = 135,000 smolts +/- 95% CI

Attachment D

Key Concepts

1. Meet Program Target
2. Under -10% Bound: Fail to meet mitigation obligations
3. Over +10% Bound: Deal with overages – mine wild fish, culling etc.

These are likely to be competing objectives

Key Concepts

1. <u>Conservation Program</u>
   a. Emphasis on not being below lower 10% bound
   b. Avoid mining wild brood
2. <u>Safety-Net Program</u>
   a. Emphasis on meeting program
   b. Avoid overages
3. <u>Harvest Program</u>
   a. Emphasis on meeting program
   b. Overages on non-listed species easier to deal with

Conclusions

- Meeting program targets carries considerable uncertainty
- Various objectives may be mutually exclusive
- Use modeling to pre-determine acceptable broodstock collection target range.
- Broodstock collection ranges tailored to each program based on ESA status, program size, population status

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Subcommittee

Date: January 15, 2020

From: Tracy Hillman, HCP Hatchery Committees Chairman and PRCC Hatchery Subcommittee Facilitator

cc: Larissa Rohrbach, Anchor QEA, LLC

Re: Final Minutes of the November 20, 2019 HCP Hatchery Committees and PRCC Hatchery Subcommittee Meetings

---

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees (HCs) and Priest Rapids Coordinating Committee Hatchery Subcommittee (PRCC HSC) meetings were held in Wenatchee, Washington, on Wednesday, November 20, 2019, from 10:00 a.m. to 3:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

Joint HCP-HCs and PRCC HSC

- Mike Tonseth will coordinate with Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) to present prespawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A). *(Note: this item is ongoing)*
- Kirk Truscott will discuss with Colville Confederated Tribes (CCT) biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A). *(Note: this item is ongoing.)*
- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multipopulation model for estimating proportionate natural influence (PNI) for the Nason and Chiwawa spring Chinook salmon programs (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will work with Mike Tonseth to test a modeling approach and prepare a white paper on the method for determining a range for the number of females to be collected for a given broodstock in the upcoming year (Item I-A).
- Greg Mackey will prepare a plan to test the feasibility of alternative mating strategies based on findings described in his previously distributed literature review (Item I-A).
- Mike Tonseth will confirm the completion date for an updated plan for Outplanting Surplus Methow Composite Spring Chinook salmon (Item II-A).

Wells Hatchery Committee

- Keely Murdoch will contact Melinda Goudy (YN) to determine if there is capacity to transfer surplus summer-fall Chinook salmon eggs to the Yakima Basin programs (Item III-A).

PRCC HSC

- Todd Pearsons will revise the 2020 Broodstock Collection Protocols to pilot test collecting all Priest Rapids Hatchery (PRH) Fall Chinook salmon in the Angler Broodstock Collection (ABC) fishery.

Decision Summary

- There were no decisions made in today's meeting.

Agreements

- There were no agreements made in today's meeting.

Review Items

- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on October 28, 2019, notifying them that the Draft "*Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs In 2020*" Plan was available for review with edits due by November 27, 2019.
- Larissa Rohrbach sent an email to the HCP-HCs and PRCC HSC on November 5, 2019, notifying them that the Draft 2020 Broodstock Collection Protocols appendices are available for review with edits due by Wednesday, December 4, 2019 (Item II-B).

Finalized Documents

- There were no documents finalized in today's meeting.

I. Welcome

A. Routine Safety Briefing

Grant PUD staff provided a routine safety briefing on emergency procedures for the meeting location. In case of emergency, Deanne Kunkel-Pavlik will call 911. Hillman reviewed the locations of the automated external defibrillator, the address for communicating with 911 written on the white board, and first-aid kits.

B. Review Agenda, Review Last Meeting Action Items, and Approve the October 16, 2019 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the HCP-HCs and PRCC HSC to the meeting.

Hillman informed the members that Steve Parker with the Yakima Nation (YN) will be retiring. Parker was the YN's representative to the HCP Policy Committee and frequently attended HCP meetings. The Committees agreed to send a congratulatory card.

Hillman reviewed the agenda and asked for any additions or changes to the agenda. The following two items were added to the agenda:

- Greg Mackey added an item to the Wells HC portion of the meeting to notify the Committee of summer Chinook salmon egg surpluses (Item III-A).
- Todd Pearsons added an item to the PRCC HSC portion of the meeting to provide an update on Nason Creek program spring Chinook salmon transfers and Carlton program summer Chinook salmon (Item IV-D).

The HCP-HCs and PRCC HSC members approved the revised agenda.

The HCP-HCs and PRCC HSC representatives reviewed the revised October 16, 2019 meeting minutes. The HCP-HCs and PRCC HSC members approved the meeting minutes as revised.

Action items from the HCP-HCs and PRCC HSC meeting on October 16, 2019, were reviewed, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meetings on October 16, 2019)*:

Joint HCP-HCs and PRCC HSC

- Mike Tonseth will coordinate with Andrew Murdoch (WDFW) to present prespawn mortality modeling results for spring Chinook salmon at an upcoming HCP-HC meeting (Item I-A).
  Tonseth said this item is ongoing.
- Kirk Truscott will discuss with CCT biologists whether elemental signature analysis could differentiate natural-origin Okanogan spring Chinook salmon from other natural-origin Chinook salmon during broodstock collection at Wells Dam for Methow Fish Hatchery programs (Item I-A).
  Hillman said he talked to Truscott and this item is ongoing.
- Brett Farman will discuss with Charlene Hurst and Mike Tonseth the potential use of a multipopulation model for estimating PNI for the Nason and Chiwawa spring Chinook salmon programs (Item I-A).
  Farman was not in attendance. Tonseth said he and Farman have located key information and are now making progress. Tonseth said this item is ongoing.

- Greg Mackey will work with Mike Tonseth to test a modeling approach and prepare a white paper on the method for determining a range for the number of females to be collected for a given broodstock in the upcoming year (Item II-C).
  Mackey said this item is ongoing.
- Brett Farman will confer with Charlene Hurst and confirm whether transfer of surplus spring Chinook salmon eyed-eggs from Methow Fish Hatchery to the Colville Confederated Tribes' 10j program is consistent with the intent of the 10j permit (Item II-D).
  Hillman confirmed that the transfer was not consistent with the 10j permit. This item is complete.
- Bill Gale will confirm whether Winthrop National Fish Hatchery (WNFH) can receive surplus spring Chinook salmon eyed-eggs from Methow Fish Hatchery (Item II-D).
  Matt Cooper confirmed that WNFH cannot receive the eggs. This item is complete.
- Mike Tonseth will prepare, and Larissa Rohrbach will distribute the appendices to the Broodstock Collection Protocols for editing by the relevant parties that were identified in the October 16, 2019 meeting (Item II-E).
  The appendices were distributed by Rohrbach on November 5, 2019, requesting that Committees members return edits to her by December 5, 2019, to be compiled in revised versions of the appendices. This item is complete.

II. Joint HCP-HCs and PRCC HSC

A. Outplanting Surplus Methow Composite Spring Chinook Salmon Adults

Mike said he spoke with Michael Humling (USFWS) and Charlie Snow (WDFW) regarding desired updates to the existing outplanting plan that was developed in 2017. Humling reviewed an analysis he had done earlier in the year to determine the potential outcomes depending on different outplanting scenarios, in terms of the effects on PNI. Many scenarios were being tested, such as outplanting only hatchery females and prioritizing MFH males for use as a safety-net brood. This would minimize the creation of HxH progeny in the wild and help insure out-year effects to PNI are reduced.

Keely Murdoch asked what will be done with the results of Humling's analysis. Tonseth said the results of the analysis will be incorporated into the outplanting plan and presented to the Committees as a revised outplanting plan for review and approval.

Murdoch asked if PNI would be calculated by reach. Tonseth said that's part of the discussion and scenarios being tested; whether to focus the outplanting on areas that would benefit most by those activities as indicated by PNI. Murdoch said the decision on where and how to outplant could depend on habitat quality. Tonseth agreed and said Charlie Snow is looking at the effects of some factors such as habitat capacity and the existing density of spawners. Murdoch said the reason for asking is that in years when there are low returns, it may be beneficial to outplant in areas that have low densities and this benefit would not be reflected by looking solely at PNI. Tonseth said his recollection was that the 2017 version of the outplanting plan was initially prepared to test the approach. This objective is still relevant to test the approach before fully implementing outplanting based on productivity metrics.

Murdoch said the conflict is that outplanting hasn't been carried out yet because of low run sizes and prioritization of broodstock for the hatchery programs, but it is in low run years when this plan may be more beneficial, and this presents conflicting fish uses. Murdoch said another conflict exists in deciding which adults should be outplanted. Tonseth said the adults chosen for outplanting are part of the scenarios that Humling is testing; for example, outplanting surplus Methow spring Chinook salmon versus WNFH spring Chinook salmon. Murdoch said the analyses presented test both sides of that issue, for instance reserving conservation program males versus outplanting. Hillman asked if the Committees need to reconsider outplanting during low return years. Tonseth said that for Methow spring Chinook salmon, at low run sizes, below 500 spawners, the permit requires management for escapement rather than PNI to allow a certain number of spawners to return to the basin.

Tonseth said they are bound by PNI requirements in the permit, but in order to test this method, they may need to work outside the PNI requirements and would need agreement from National Marine Fisheries Service (NMFS) that a given year would not be included in 5-year PNI calculations. Pearsons said in previous years Broodstock Collection Protocols (BCPs) noted that the priority was for fish to go to WNFH, because the spawning outcome at WNFH is known whereas productivity after outplanting is unknown. Pearsons asked if that logic is being challenged now with an alternative perspective. Tonseth said it's not necessarily a challenge, but a method for allowing for multiple choices during broodstock collection. For instance, Humling tested retaining only Methow Component males and using females for outplanting. This practice would reduce pNOB slightly but allows wild males to pair up with Methow Component hatchery females to spawn naturally.

Murdoch asked if the Committees will be able to review the plan in time for incorporation into the 2020 BCPs. Tonseth said the outplanting plan is not likely to be ready by December and suggested maintaining the plan as a stand-alone document until the method is proven in the future. Tonseth said their expectation is to prepare the plan in time for collection of 2020 spring Chinook salmon broodstock. Tonseth said they are restructuring the document with a suite of options to allow the Committees to decide on the optimal approach(es) depending on multiple metrics. Tonseth said he, Humling, and Snow will be discussing the analysis next week. The plan will be provided in 2020 for Committee review.

Mackey said the 2017 outplanting plan has detailed methods for meeting permit conditions using the multi-population PNI model for the Methow Basin.

Mackey said one other option is to outplant eggs. After natural spawning occurs, additional eggs can be outplanted in areas where spawning has not occurred to target areas with low densities. Mackey said it is also another way to make use of surplus eggs. Tonseth said it is challenging to measure success of egg outplanting and it is challenging to construct artificial redds. Murdoch said it may actually be more difficult to document success of outplanting adults because it is difficult to track spawning after adults have been moved into an area, but the advantage of outplanting adults is that it reduces any domestication selection on eggs in the hatchery. Tonseth said outplanting adults reduces but does not eliminate all domestication selection because the hatchery staff are selecting which fish to outplant. Mackey said it would be more difficult to know whether outplanted adults have spawned in areas with low densities. Mackey said it would be relatively easy to electroshock juveniles to confirm that the productivity was the result of outplanted eggs. Tom Kahler said a Parentage Based Tagging genetic analysis could be performed on offspring as well to confirm parentage. Tonseth said they would need to ensure NMFS agrees that outplanting of eggs was consistent with the permit, and how NMFS would view outplanting eggs in terms of calculating PNI. Graf said he researched some backpack pump units that blow the gravel clean and then inject eggs. Mackey said this pump technique is capable of rapidly outplanting hundreds of thousands of eggs.

Tonseth said he will confirm the completion date of the outplanting plan.

B. Broodstock Collection Protocols Progress Update

Hillman reviewed the 2020 BCP topics for discussion. Hillman asked whether there were questions about editing the BCP appendices (Table 1). Tonseth reminded the Committees that some appendices won't be ready for December because they depend on run forecasts. Tonseth said the Technical Advisory Committee (TAC) forecast is typically available in late December for estimating returns. Tonseth said this information will be added to the appendices as the information comes in. Larissa Rohrbach requested that edits be sent to her for compilation by December 4.

Pearsons asked if the goal was to simply update the numbers in the appendices. Tonseth said yes, and the data provided in the appendices will be used to draft the body of the BCPs. Tonseth said most of the appendices simply require review, for instance to confirm that site-specific plans are still accurate.

Tonseth noted that Appendix K on the YN coho salmon program is to be completed by the YN. Murdoch confirmed that she will strive to make Appendix K available by the end of January. Tonseth said the goal would be for it to be distributed with the February draft BCPs.

Tonseth said USFWS should be responsible for Leavenworth National Fish Hatchery (LNFH) and WNFH forecasts. Matt Cooper said those also tier from the TAC forecasts.

Table 1
2020 Broodstock Collection Protocols Assignments

Appendix	Title	Assigned Parties	Notes
A	2019 BY Biological Assumptions for Upper Columbia River Spring, Summer, and Fall Chinook salmon and 2020 BY Summer Steelhead Hatchery Programs	WDFW and PUDs	
B	Current Brood Year Juvenile Production Targets, Marking Methods, Release Locations	All	
C	Return Year Adult Management Plans	WDFW lead	Contingent on run forecast available in Jan/Feb 2020
D	Site-Specific Trapping Operation Plans	PUDs and M&E staff YN to review	Identify plans and ensure they are still accurate
E	Columbia River TAC Forecast	WDFW	Forecast available in late Dec 2019/early Jan 2020
F	Annual Chelan, Douglas, and Grant County PUD M&E Implementation Plans	PUDs	Provide links
G	DRAFT Hatchery Production Management Plan	All	
H	DRAFT Preferred Alternative for 2020 BY and Beyond, Methow Sub-basin Conservation Steelhead Programs	Revisit after completion of 2019/2020 steelhead return	Pending discussion by Joint Fisheries Parties; concern about acquiring broodstock in the spring
I	Program Specific Rearing and Release Descriptions	PUDs and M&E staff	Staged release at Priest Rapids Hatchery to be addressed
J	2019 BY Spring and Summer Chinook Disease Management Plans	CPUD M&E staff and WDFW veterinarian (Megan Finley)	
K	2020 YN Coho Broodstock Collection Plans	YN	
General	Species-Specific Run Forecasts	WDFW, USFWS (LNFH, WNFH)	

Notes:
M&E: Monitoring and Evaluation

C. NMFS Consultation Update

Representatives of the CCT and NMFS were not in attendance. Committees members noted that the recurring agenda item for a NMFS Consultation Update is no longer necessary because all permits have been finalized.

Tonseth said a recalculation in 2021/2022 could force re-consultation. Tonseth said 2024 would be the first release year of offspring after recalculation. He added that consultation discussions should start at about the same time as recalculation discussions in 2020.

D. Annual Skaha Lake and Okanogan Lake Sockeye Reintroduction Update

Hillman introduced Ryan Benson (Okanagan Nation Alliance), who gave a presentation entitled, "*Skaha Lake Sockeye Re-introduction Program Update*" (Attachment B).

Slide 2: Benson provided an annual summary of hatchery operations. Benson said that 2015 was affected by massive fish kills in the lower Okanogan River due to warm temperatures. In 2019, mean egg take was low (1,650 average eggs per female) because many of the females collected were half-spent already. The numbers in 2019 also reflect the effects of poor returns in 2015; however, improvement from 2015 shows growth of the cohort. In 2019, all females to be used for broodstock were retained instead of returning females that were not ripe to the river. They are now held in the hatchery until becoming reproductively mature.

Each year milt from a proportion of the males is cryo-stored as a contingency in case of a population crash. Managers typically use milt from previous years to test the viability of the frozen sperm and to fertilize a small number of sample eggs; however, this was not done in 2019 due to low run sizes, but milt was archived in 2019.

Starting in 2016, the release strategy has been to match peak emergence of fry because temperatures that vary by 5 to 10 degrees year to year in spring can shift emergence timing considerably. The program releases early, mid, and late release groups in March, April, and May, respectively. No differences in survival between release groups have been detected yet, but managers are continuing to monitor. The advantage is a reduction in hatchery operational costs when fish are released early.

Pearsons asked about the fate of the males used for the milt cryopreservation program. Benson said the milt is collected from a male and that male is returned to the river. Pearsons asked if a male could be spawned in one year and milt used in later years. Benson said the males used for cryopreservation are not spawned in the year in which they were collected.

Mackey asked what the egg take goal is. Benson said it is based on the escapement estimate, a target of 30,000 adults. Hillman asked what the capacity of the hatchery is. Benson said 5 million eggs.

Slide 3: Benson said in 2019 there were a high number of 3-year-olds, mostly jacks, and some jills. To augment the collection in 2019, approximately 32 females (6.2% of total egg take) were collected from Penticton Channel. Jacks and jills were also collected from an effluent pipe from the hatchery that was protected by bars that were spaced so that only smaller adults passed though. Benson said they are improving practices in order to streamline operations for the large return expected in 2020.

Hillman asked if 3-year-olds are spawned. Benson said yes for females. This reflects natural processes as 3-year-old females are observed on the spawning ground. Pearsons asked about the origin of fish that return to the Penticton Channel and the hatchery effluent pipe. Benson said they haven't finished the analysis of otoliths but suspect they are mostly hatchery-origin fish.

Slide 4: Benson said in 2019, all fry were released in Lake Okanagan for the first time. Otolith thermal marks were used to mark three different groups for release into three different sites in the lake.

Slide 5: Benson presented estimates of survival and travel time to Bonneville Dam for BY 2017 juveniles. Travel time and survival was lower in 2019 compared to past years. Benson suspects it is related to lower flows in 2019. Survival in the lake is monitored by purse seining, which has been more successful than other methods, though it can be difficult to catch the fish if they are located near the bottom of the lake. To minimize handling during passive integrated transponder tagging, fish are tagged directly on the purse seiner during collection rather than transporting fish to a separate tagging location.

Willard asked why travel time from Skaha Lake looks faster than travel time from Osoyoos Lake, which is farther downstream. Benson said its likely because Skaha Lake sockeye are a bit larger than the wild fish from Osoyoos Lake. Willard asked about release times and detection sites. Benson said there is one detection point near the release point; however, the detection probability is better at Bonneville Dam. Benson said survival and travel time are calculated from the time they are released after tagging into the lake to redetections at downstream sites. At this time, tagging can be done within 2 to 3 days so there is less lag time between tagging and release into the lake than in the past.

Slide 6: Skaha Lake Natural Production. In 2011, high water levels allowed adult sockeye to enter Skaha Lake and spawn naturally. Fish may move upstream via the Skaha Dam fishway. Many fish pass over an outflow gate when water levels are high. There was no need to stock any fry into Skaha lake due to a naturally high escapement in 2018.

Slide 7: In-lake monitoring. Hatchery-origin fry in Skaha Lake had a lower survival rate than natural-origin fry monitored in Lake Osoyoos. Benson said the release site experiment is an attempt to improve upon survival rates. Mackey asked if fry are fed before release. Benson said yes.

Benson said there is potentially an optimum loading density for hatchery fry in Skaha Lake, indicated by suppressed growth in 2018. Various factors affect productivity in Skaha Lake, in particular discharge rate through the lake and natural pelagic fish community dynamics of sockeye, kokanee, and whitefish. Whitefish show a boom and bust pattern. Benson said there may be a need to calculate the optimum release numbers each year.

Historically, there was a concern that the Skaha Lake kokanee population could crash due to competition with mysid shrimp and reintroduced sockeye. Results show the kokanee stock has increased in recent years based on number of spawners and biomass in the lake. Skaha Lake does not appear to have a problem with competition. The main grazers of zooplankton are 2 to 3-year-old kokanee; the grazing impact of sockeye fry is minimal compared to kokanee.

Slide 8: Lab development. Lab tests include the following:

- qPCR
- Chinook salmon biosampling of carcasses
- Northern pike
- Water quality
- Macroinvertebrates

Tests that use qPCR are used to screen for disease (Infection Hematopoietic Necrosis and Bacterial Kidney Disease), environmental DNA (eDNA) for other species of concern, and for invasive species. Benson said they expect to expand lab work with recent funding from the Province of British Columbia.

Slide 9: Okanagan Basin Salmon Restoration Sub-Committee. Benson said there is a new mandate that directs reintroduction in the entire basin, including Skaha Lake. The mandate also addresses invasive species and other endangered species and uses an ecosystem approach including habitat initiatives. Benson said there is a Draft Okanagan Lake Recovery Plan and they will eventually move on to recovery planning for other lakes upstream. There was recent approval and support for release of 4.2 million fry into Okanagan Lake. One concern to address in the future is sockeye residualization and hybridization between kokanee and sockeye.

Slide 10: Okanagan Lake Program. The Department of Fisheries and Oceans, Canada, has approved a long-term hatchery outplanting program contingent on monitoring and evaluation program planning and implementation. There is a technical sub-committee overseeing the draft plans. The groups are working toward activating the fishway over Penticton Dam at the outlet to Okanagan

Lake and to tag and plant 100 adults to track their movement in Okanagan Lake. Ceremonial stocking has been done since 2016. Benson said productivity is lower in Lake Okanagan compared to Skaha per unit area; however, the potential productivity could be larger than other lakes like Skaha due to the size of Okanagan Lake.

Dave Duvall (Grant PUD) asked what the lake productivity estimates are based on. Benson said it is based mainly on the limnetic characteristics of the lake and not a formal analysis. Benson said this does not take into account spawning in natural tributaries. Restoration and passage monitoring into tributary creeks may improve natural spawning.

Benson said the Okanagan River Restoration Initiative has expanded restoration actions. The latest actions are to add spawning gravels to Penticton Channel.

Pearsons asked if fish that get to Okanagan Lake can access lakes farther upstream. Benson said he did not know but that he thinks the potential is there and it would not be a major task to expand the distribution of sockeye into those lakes. Pearsons asked whether upstream lakes are sockeye-producing lakes. Benson said he thought so; however, the accessibility to tributaries is unknown.

Slide 11: The Penticton Dam fishway at the outlet of Okanagan Lake was activated in 2019 allowing the first fish passage since 1953. Benson said in the past, fish passage was blocked at points downstream so there was no reason to open the Penticton Dam fishway. Flows and boards were adjusted in 2019 to test feasibility. No sockeye were observed in the fishway. Benson said they may have missed the migration window by the time the fishway was running and some fish that were spaghetti tagged at the fishway were observed spawning downstream. Block nets are used to capture fish at the upstream end of the fishway. Benson said they were able to identify improvements to the 1950s engineering for future funding, such as an automated gate that adjusts along with lake levels that can fluctuate up to 1 meter each year, an improved capture platform instead of the block net, and a passive integrated transponder antenna. Benson said there is community support for fish passage into Lake Okanagan. Early returns from the 600,000 fry outplanted to the lake could appear next year.

Pearsons asked what the expectation of a large run in 2020 is based on. Benson said it is based on the number of fry outplanted in 2018. The purpose of activating the fishway this year was to work out the challenges prior to next year’s run.

Pearsons congratulated Benson on achieving fish passage into Okanagan Lake. Benson said the perspective of the British Columbia Provincial government has changed completely as a result of a directive that the Province must follow to the letter The United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP). The relationship between Okanagan Nation Alliance and the Province has changed completely and now they share the same perspective in terms of taking an ecosystem management approach. Benson said there is also a mandate for the Province to manage for resident fish. Results show that improving conditions for anadromous fish are improving the productivity of resident fish.

Murdoch also congratulated Benson on Okanagan Nation Alliance's achievements. Murdoch asked if the increase in kokanee is a result of residualism of sockeye outplants or habitat improvements. Benson said he thinks its habitat improvements. There are two spawning modes observed in the channel. Benson said some fish are switching life histories, which is complicating analyses. Benson said his perspective is that they are different ecotypes of the same species. Benson said in the traditional ecological knowledge of Okanagan elders there is a term for hybrid in the language. Murdoch said the concept of hybrids is interesting because they are the same species but noted that managers were able to observe kokanee genetics.

Murdoch asked if historically both ecotypes were in the lakes. Benson said yes, historically they were probably both there and that kokanee ecotypes have been deviating farther from the natural anadromous stock. Benson said that hybrids don't do as well, they appear to be an intermediate form. However, if the elders were aware of them, perhaps they had a purpose as a food for other species or overall productivity of the system. Benson said monitoring will show whether the genetics of the ecotypes continue to diverge. Murdoch asked if isolation is the reason for genetic differences. Benson said historically they were probably the same form. Mackey said when kokanee and sockeye are sympatric, kokanee are much more efficient at sequestering carotenoids than sockeye, so there are some physiological and genetic differences.

Pearsons asked Benson what changed with the Provincial perspective in recent years. Benson said this is a change that has occurred across the Province due to the outcomes of a truth and reconciliation commission that was similar to the post-apartheid commission in South Africa. Benson said there was a travelling commission that listened to all parties. The federal government signed on to the commission as well as the Provincial government. Benson said the outcomes have trickled down throughout all areas of social sciences, agriculture, and natural resources like fish and forestry. Benson said the link to UNDRIP forces changes to be implemented now. Benson said existing technical groups including the Canadian Okanagan Basin Technical Working Group have been a successful model for cooperation that has been in place since the 1990s to facilitate change.

Hillman thanked Benson for his presentation.

III. Wells HC

A. Surplus Wells Fish Hatchery Summer Chinook Eggs

Greg Mackey said that there are approximately 120,000 surplus eggs from the Wells Hatchery summer Chinook salmon egg treatment study and likely more than that from the production programs due to high fecundity and survival this year. Eggs will be shocked late this week and mortalities will be picked early next week. There is a need for the eggs to be transferred or sacrificed by December 2, as they will hatch between December 8 and 9, 2019. Mackey also said there are likely to be surplus summer Chinook salmon eggs from the Wells Subyearling Program due to high fecundities in the broodstock. The surplus eggs will be incubated on a program for developing subyearling smolts.

IV. Rock Island/Rocky Reach HC

A. Surplus Chelan Falls Summer Chinook Eggs

Tonseth said WDFW is also expecting a surplus of 400,000 to 600,000 eggs in the Chelan Falls summer Chinook program. Tonseth said he is waiting to hear from Kirk Truscott on CCT's needs and that the Chelan Falls program eggs will be shocked and picked by January. Tonseth has received some requests for small numbers of eggs for salmon in the-classroom projects but no other programs need large numbers of surplus eggs.

Willard asked Tonseth to remind the committees why there was such a large surplus in the Chelan Falls program. Tonseth said for 2019 one collection site that was identified was the Wells trap where 380 adults were collected. Concurrently, Chelan PUD coordinated beach seining with CCT and installation of an instream picket weir to collect broodstock directly from the Chelan River. Tonseth said and Willard confirmed the picket weir was successful after some initial installation challenges. Tonseth said the fish from the Chelan River were collected in warm water (>70°F) so there was uncertainty around egg quality and fecundity. Given those uncertainties, WDFW decided to spawn all fish collected. Tonseth said pre-spawn survival of the river-trapped fish was better than fish trapped at Wells Dam. Tonseth said they have only met program targets in 2 of 5 recent years. Tonseth said they did not predict that the Entiat National Fish Hatchery would have similar success this year and they were able to supply eggs to the YN programs. Tonseth said unless there is a program identified for the surplus eggs, they will be destroyed. Tonseth said it is not expected to have a surplus next year as a number of uncertainties in broodstock collection for the Chelan Falls program have been addressed. Willard said in January she will present a summary of Chelan Falls broodstock collection results.

Mackey said the CCT's Chief Joseph Hatchery may be the only outlet for surplus fish at this time. Tonseth agreed and said he is waiting to hear back from Truscott. Truscott suggested that in the interim, Mackey reach out to Matt McDaniel, the manager at Chief Joseph Hatchery, to determine if there is capacity at Chief Joseph Hatchery for the surplus eggs.

Keely Murdoch said she will ask Melinda Goudy (YN) if there is capacity in the Yakima Basin programs for more eggs.

V. PRCC HSC

A. Approve the October 16, 2019 Meeting Minutes, Committee Updates, and Meeting Summary Review (Todd Pearsons)

The PRCC HSC representatives approved the October 16, 2019 meeting minutes as revised.

Hillman reviewed the agenda. He explained that the intent of the agenda item on White River spring Chinook salmon recovery was to identify questions for Craig Busack (NMFS). His responses to the questions will support decision-making on a White River spring Chinook salmon hatchery program.

B. Priest Rapids Fall Chinook Salmon Broodstock Collection

Todd Pearsons gave a briefing on the Angler Broodstock Collection (ABC) Fishery that occurred in the Hanford Reach for the collection of fall Chinook salmon broodstock. The Coastal Conservation Association (an angling advocacy group; CCA) is the group that coordinates the anglers. The derby was capped at 100 boats for logistical reasons. Slots were filled in the first week of registration.

Pearsons said this year there were three fishing sites instead of two (Vernita Bar, White Bluffs, mid-reach). In total, 1,572 fish were collected over 3 days, which was the highest number ever collected. Last year 1,342 fish were collected. In the first year, 2012, 69 fish were collected.

Pearsons said there was good survival because all transfer boats were equipped with oxygen. Pearsons said there were enough natural-origin males to allow the Priest Rapids Hatchery (PRH) to make 1:2 crosses (M:F) instead of 1:4 crosses. In the past, 1:4 crosses were done to maximize use of natural-origin males; however, 1:2 is the typical protocol.

Murdoch asked whether the timing of the Columbia River recreational fishery closures this year occurred just before the ABC fishery as it did last year. Pearsons said yes. Murdoch asked if that was part of the angling success. Pearsons said yes, that was likely part of it, but also the publicity and participation increased this year. The CCA portrayed it as the largest fishing derby of its type in the world. Murdoch asked if the fishery will be closed at the same time in the future. Tonseth said they looked through the fishery regulations and the answer is yes, the current regulatory structure in place over the past 2 years will continue to be in place over the next 2 years, creating the lag time between closure of the recreational fishery and implementation of the ABC fishery. Pearsons said the fishery remains closed in the area of the derby.

Murdoch asked if there was an entrance fee. Pearsons said yes. He said there is a benefit to the CCA in that they acquire a lot of new members through this event. Pearsons said Grant PUD provides funding for prizes. Pearsons said one thing that has changed is that there are a number of fishing guides participating. Pearsons said CCA likes it because it increases their membership, anglers like it because they can fish waters that are typically closed to them and they are contributing to the hatchery program, and guides like it because they can book trips for the derby. Experienced anglers have been instrumental in the popularity of the program and in increasing numbers of fish captured.

Pearsons said in the 2019 BCP it was agreed to collect fewer fish at the Priest Rapids Off Ladder Adult Fish Trap (OLAFT). The target number to be trapped at the OLAFT was brought down to 650 fish, which was not achieved this year, but numbers captured in the ABC fishery greatly exceeded the target of 600 fish.

Tonseth said WDFW supports moving away from collecting natural-origin fall Chinook salmon at the OLAFT. Tonseth said Paul Hoffarth (WDFW) was initially concerned that the number collected in the ABC fishery would not be adequate, but this number has been large in the past 2 years. Tonseth proposed collecting broodstock only via the ABC fishery in 2020. Hillman asked Tonseth to remind the Subcommittee why WDFW prefers to not use the OLAFT for broodstock collection. Tonseth said there is uncertainty about the origin of the fish that ascend Priest Rapids Dam (PRD), whether they are returning to the Priest Rapids pool or are part of the aggregate that spawns in the Upper Columbia Basin, and it's unknown what contribution the adults ascending PRD are making to upstream populations.

Pearsons said he was initially apprehensive of relying solely on the ABC fishery because the reason for use of the OLAFT and fishery is to select the type of fish to meet a PNI target of 0.67. Pearsons said he has become more comfortable with the idea of not using the OLAFT because PNI has been high the last few years. Pearsons suggested using the OLAFT as a back-up option for collecting fish without having to develop a new proposal if there is a decline in PNI in future years below the target of 0.67. Pearsons suggested not collecting at the OLAFT in 2020 but treating the approach as a pilot method for the next few years in case an adequate number of fish are not captured in the ABC fishery. Tonseth said that would be a reasonable approach but would require CCT approval. Tonseth said the success of the ABC fishery depends on consistency in return timing, fishery timing and run size, and at this time there is no reason to expect these factors to change.

Murdoch said she would want to verify during the pilot years that the PRH program would backfill with hatchery-origin fish if the program runs short. Pearsons said they try to collect fish at the OLAFT that are not known to be hatchery fish, but they do spawn hatchery fish as needed. Murdoch said if PRH doesn't meet production it would likely be due to a low run size, not because of failure of the ABC fishery.

Tonseth said the PNI target is compared to a 5-year mean, so one year of PNI below the target of 0.67 would be acceptable. Pearsons said yes, but if PNI is very low in one year, for instance as low as 0.2, it may not be possible to elevate the 5-year mean PNI in subsequent years.

Pearsons asked if this proposed change to broodstock collection should be written into the BCPs now or wait until Truscott is available to approve this pilot plan. Hillman and Tonseth advised Pearsons to go forward with edits to the BCP.

C. White River Spring Chinook Salmon: Recovery Questions

Hillman said the intent of the discussion on White River spring Chinook salmon recovery is to identify questions for Craig Busack (NMFS) before he retires. His responses will support decision-making on a White River spring Chinook salmon hatchery program. Spawning aggregates of the Wenatchee spring Chinook salmon population were discussed. Major spawning areas (MSAs) include the Chiwawa River, White River, Nason Creek, Little Wenatchee River, and upper Wenatchee River; minor spawning areas (mSAs) include Chumstick Creek, Peshastin Creek, Icicle Creek, and Mission Creek.

Tracy Hillman recorded questions for Craig Busack as they were posed in the meeting. Hillman presented the initial question about the necessity of the White River spawning aggregate for recovery of the Wenatchee River spring Chinook salmon population.

Murdoch asked if Busack is working closely with Northwest Fisheries Science Center (NWFSC) because at yesterday's PRCC meeting, Scott Carlon (NMFS) suggested that scientists at the NWFSC may be changing their thoughts on the importance of the White River spawning aggregate to the recovery of the Wenatchee River spring Chinook salmon population. Murdoch noted that the importance of the spawning aggregates are written into the recovery plan so that would represent a change to the recovery plan. Murdoch said in her view this would represent a major change to the recovery plan. The implication is that there is no concrete decision at this time but the topic may be under discussion. Graf agreed that the view was not specific, so a general question to be ask is what is the NWFSC's recent view on the White River spawning aggregate.

Murdoch posed questions from Tom Scribner (YN). Scribner asked if the White and Little Wenatchee spawning aggregates are limited by predation in the Lake Wenatchee, how do the federal regulatory agencies interact to resolve this issue? Is there a willingness by NMFS to rewrite the recovery plan? Tonseth agrees this is difficult because the programs are bound by the direction in the recovery plan. Tonseth asked, given the uniqueness of Lake Wenatchee and the White River and Little Wenatchee spawning aggregates, should they be considered one aggregate? Matt Cooper asked how often the recovery plan undergoes review. Murdoch said it doesn't. Tonseth said the plan was written in 2007.

Pearsons asked how different the White River spring Chinook salmon spawning aggregate needs to be from other spawning aggregates to be considered independent in terms of Viable Salmonid Population (VSP) parameters such as diversity. Pearsons asked, if that genetic diversity is lost and the aggregates are no longer different, how is diversity recovered? Tonseth suggested reframing the question to ask as how different all the spawning aggregates need to be to achieve the diversity component of recovery? Tonseth asked whether the plan should identify genetic characteristics that need to be met to identify a group as a spawning aggregate. Murdoch said there are specific goals for the abundance metric of VSP but there are not goals for the diversity metric. Murdoch said diversity at this time represents post-1940s divergence within the Wenatchee River spring Chinook salmon population and the goal would be to maintain the divergence that has occurred. Hillman said metrics for spatial structure and diversity are combined into a matrix and the results are used to determine if the population is at very low, low, moderate, or high risk of extinction. There are targets for spatial structure and diversity. For example, the recovery plan identifies how many spawning aggregates need to be populated with natural-origin fish. Hillman said the goal is to maintain natural spawners in 4 of 5 MSAs and in one mSA downstream from Tumwater Canyon. Thus, one or both of the MSAs upstream of Lake Wenatchee are needed for recovery.

Tonseth said there are surplus fish from Endangered Species Act-listed hatchery programs returning upstream of the Icicle Creek that currently cannot be used at LNFH because of NMFS' definition of what constitutes an Endangered Species Act-listed fish; that is, hatchery-reared fish included as part of the listing status. Kahler said in the Methow River, Methow Hatchery-origin fish are declared surplus to the recovery of the population, so that they can be surplussed for adult management or utilized as broodstock in other hatcheries. Tonseth said if listed hatchery fish could be delisted, they could be used at LNFH. Cooper said, hypothetically, a proposal would be for LNFH to be set up as a safety net program, similar to WNFH to maintain mitigation obligations using the Carson stock. Tonseth said possibly, but not at the expense of allowing natural-origin fish to spawn in the Icicle Creek, reclaiming the Icicle Creek spawning aggregate. Cooper said hypothetically, how would recovery of the Icicle Creek aggregate affect the White and Little Wenatchee aggregate. Tonseth said if the Icicle Creek aggregate were recovered to a level of a major spawning area, the White River and Little Wenatchee River could be considered minor aggregates. Murdoch said that scenario is highly speculative.

Pearsons asked, if money were put toward recovery of an aggregate, would the choice be to invest in the White and Little Wenatchee rivers, or in Icicle Creek. Tonseth and Pearsons agreed it would be Icicle Creek due to the quality and quantity of habitat in Icicle Creek.

Murdoch said all of the ideas discussed would require redrafting the recovery plan and asked who the authors of the recovery plan are. Hillman said it is NMFS's plan. NMFS and the State of Washington provided the Upper Columbia Salmon Recovery Board (UCSRB) with funds to help NMFS write the plan. Involving the UCSRB led to a grass-roots effort. Murdoch said reopening the plan would require reinitiating that effort.

Murdoch said if there is an opening to reconsider aggregate status in the recovery plan, the Upper Wenatchee River major spawning area should be discussed. Murdoch said the upper Wenatchee River MSA has very low productivity and the few natural-origin fish that return to the Wenatchee River do not typically spawn in the upper Wenatchee MSA. Spawners in the upper Wenatchee River MSA tend to be hatchery-origin strays. Murdoch suggested that perhaps the Upper Wenatchee MSA should not be considered a MSA. Pearsons agreed and remarked the data show that is not a self-sustaining spawning location and serves more as a sink. Tonseth agreed and commented that the data on spawning success and survival were not available when the plan was written. The plan was written based on where fish were observed spawning.

Hillman projected the recovery plan for reference. Hillman showed the recovery criteria for abundance, productivity, diversity, and spatial structure. Pearsons said he is interested in one of the criteria on genetic variation; how different do the stocks have to be (number 1c)? Hillman said the assumption was made that there was some differentiation between spawning aggregates. Specifically, the focus on the White and Little Wenatchee was because it was thought those aggregates were substantially different from others. Pearsons said this was written before more recent information was provided by geneticists (e.g., provided by the panel of genetic experts consulted in late 2018). Pearsons noted that differentiation of the White River fish was determined to have occurred over just two generations, which may not necessarily be adaptive variation, but rather the result of a founder effect. Murdoch said she was also surprised by how little genetic difference there was between populations. Graf said genetic reports have shown that diversity within the Chiwawa aggregate is greater than between aggregates.

Hillman showed the risk analysis scores for the individual spawning aggregates and the criteria for scoring abundance/productivity risk factors (Appendix B to the recovery plan). Hillman said NMFS reevaluates the status of the populations every 5 years to determine if the viable population parameters (abundance, productivity, spatial structure, and diversity) have improved.

Matt Cooper asked what the end goal is for the PRCC HSC. Is the Subcommittee's task to evaluate hatchery actions to move the needle toward recovery? How should the Subcommittee evaluate other actions that contribute to recovery? Murdoch said many of these questions came up when tasked with the question of whether to reinitiate a White River hatchery plan. Pearsons said gathering all the information possible will help the committee determine what program should occur in the White

River. Hillman said one reason to get this information from Busack is to help inform the subcommittee as to the need for a White River Hatchery program. If a program is deemed necessary, feedback from Busack will further inform what fish would be collected for broodstock, how many broodstock would need to be collected, and how many juveniles would need to be produced in the program. Pearsons said using brood from other sources counteracts the goal of recovery to protect or increase the diversity of the White River aggregate.

Murdoch said a lot of research has been done over the past 10 years and a key question is if there are criteria identified that are no longer relevant based on recent results and whether there is an opportunity to revise the criteria. Murdoch asked Hillman if a question like that would carry more weight coming from the HSC or from the UCSRB, and whether the UCSRB would engage on the issue. Hillman said it may get more traction if it is supported by the UCSRB. Hillman said bringing all parties along to create the recovery plan was very challenging; the UCSRB may not be interested in reopening the plan. Murdoch suggested finalizing some additional research such as the reproductive success study. If the science suggests some of the goals are no longer supported, the UCSRB may support reopening the recovery plan. Hillman suggested waiting for the results of the next status review (to be completed in 2020) to see if the populations have moved toward recovery. Hillman noted that in the last status review, NMFS determined that populations in the Upper Columbia were holding steady.

Pearsons suggested asking Busack these questions and the PRCC HSC can take a particular course of action depending on his responses.

Pearsons added a few more questions. Pearsons asked, if the White River genetic signature is lost (has been lost already or is lost due to hatchery actions), what is the path to recovery? Murdoch said Scribner had a similar question. Murdoch said the Relative Reproductive Success Study is showing that the hatchery fish (Chiwawa River strays) spawning in the White are equally as productive as the natural-origin fish spawning in the White River. So why is there still a distinct signature for the White River aggregate? Pearsons said the White River genetics may be diluted and whether the uniqueness of the aggregate has been maintained may come to light in the 10-year Comprehensive Report (to be completed in 2020).

Pearsons asked whether NMFS would support a composite broodstock. Murdoch added if the spawning aggregates are not genetically distinct, how would it change NMFS view on supplementation? Murdoch said the current interpretation is to wait and see if the aggregates are genetically distinct.

Pearsons asked how hatchery-origin spawners contribute to recovery if they don’t contribute appreciably to increasing the production of natural-origin offspring. Pearsons said the interpretation of VSP criteria is that hatchery fish don't count toward recovery, and in fact they can count against the status of the aggregate. Pearsons asked whether starting a hatchery program would contribute to recovery in terms of the VSP criteria or count against it? Cooper said hatchery fish may count towards diversity or other metrics. Murdoch said a hatchery could contribute by maintaining natural-origin productivity. Murdoch said hatcheries won't bring an aggregate to recovery if the limiting factors are not addressed. Hatcheries can buy time and offer an extinction risk buffer.

Hillman said responses from Busack should provide members with some of the information they need to support or reject a White River hatchery program. Answers to these questions provide Subcommittee members justification for making recommendations.

Hillman suggested if Busack cannot represent NMFS' position on these questions, the questions should be provided to someone else at NMFS. Hillman suggested allowing the PRCC HSC members an opportunity to review the list and provide edits/comments by December 5. The list can then be sent to Busack.

The draft list of questions for Busack, recorded by Hillman during the preceding discussion is as follows:

1. Is the White River spawning aggregate necessary to the Wenatchee spring Chinook salmon population in regards to meeting Viable Salmonid Population criteria?
2. What is the NOAA Science Center's most recent view on the importance of the White River spawning aggregate?
3. If survival data indicate the bottleneck for White River spring Chinook salmon is predation (e.g., bull trout) within Lake Wenatchee, how do the federal regulatory agencies interact to resolve the issue?
4. If the White River and Little Wenatchee spawning aggregates are important to recovery and both suffer from similar agents of mortality within Lake Wenatchee, how will NOAA address recovery without one or both aggregates?
    a. Can both aggregates be considered one aggregate?
    b. Is there a need to revise the existing recovery plan?
5. How important is the White River aggregate to the overall genetic diversity of Wenatchee spring Chinook salmon?
    a. How much within-population genetic variation is needed for recovery?
6. If the White River genetic signature is lost, can recovery still be achieved?
    a. If so, how do we achieve recovery without the White River genetic signature?
7. Would NOAA support a composite broodstock hatchery program for the White River?
8. If White River spring Chinook salmon are not genetically distinct from other Wenatchee spring Chinook salmon aggregates, what would be NOAA's view on White River supplementation?

9. If hatchery-origin fish do not contribute to natural-origin fish, would adding another supplementation program in the Wenatchee contribute to recovery?

D. Chinook Salmon Transfers from Eastbank Hatchery

Todd Pearsons updated the Subcommittee on transfers of spring Chinook salmon from Eastbank Hatchery to acclimation facilities.

Nason Creek spring Chinook salmon were transferred to the Nason Creek acclimation facility in the third week of October. Survival was good.

Carlton summer Chinook salmon were transferred during the second week of October. They are currently being held on groundwater because of past health concerns, and mortality rates have been very low. Pearsons said the use of groundwater seems to be helping with fish health.

VI. Administration

A. Next Meetings

The next HCP-HCs and PRCC HSC meetings are December 18, 2019, January 15, 2020, and February 19, 2020, at Grant PUD in Wenatchee, Washington.

A determination will be made in early December whether the HCP-HCs and PRCC HSC will convene in person or via conference call.

Skaha Lake Sockeye Re-Introduction Program Update

November 20, 2019

Wenatchee, WA

Presented to PRCC Hatchery Subcommittee

syilx Okanagan Nation Alliance

OKANAGAN NATION AQUATIC ENTERPRISES LTD.

Attachment B

Hatchery Operation

Attribute	2014 (start up)	2015	2016	2017	2018	2019
Fecundity mean	2,439	2,096	2,144	2,095	1,864	1,650
Total eggs collected	2,452,000	508,000	5,256,000	1,312,429	4,148,460	720,459
Trap & Transport eggs	N/A	N/A	800,000 (15%)	514,000 (39%)	847,060 (20%)	**100%**
Egg to fry survival	71.8%	72.0%	95.1%	93.9%	90.9%	N/A
Cryofreezing samples	40 males	33 males	23 males	35-40 males	40 males	24 males

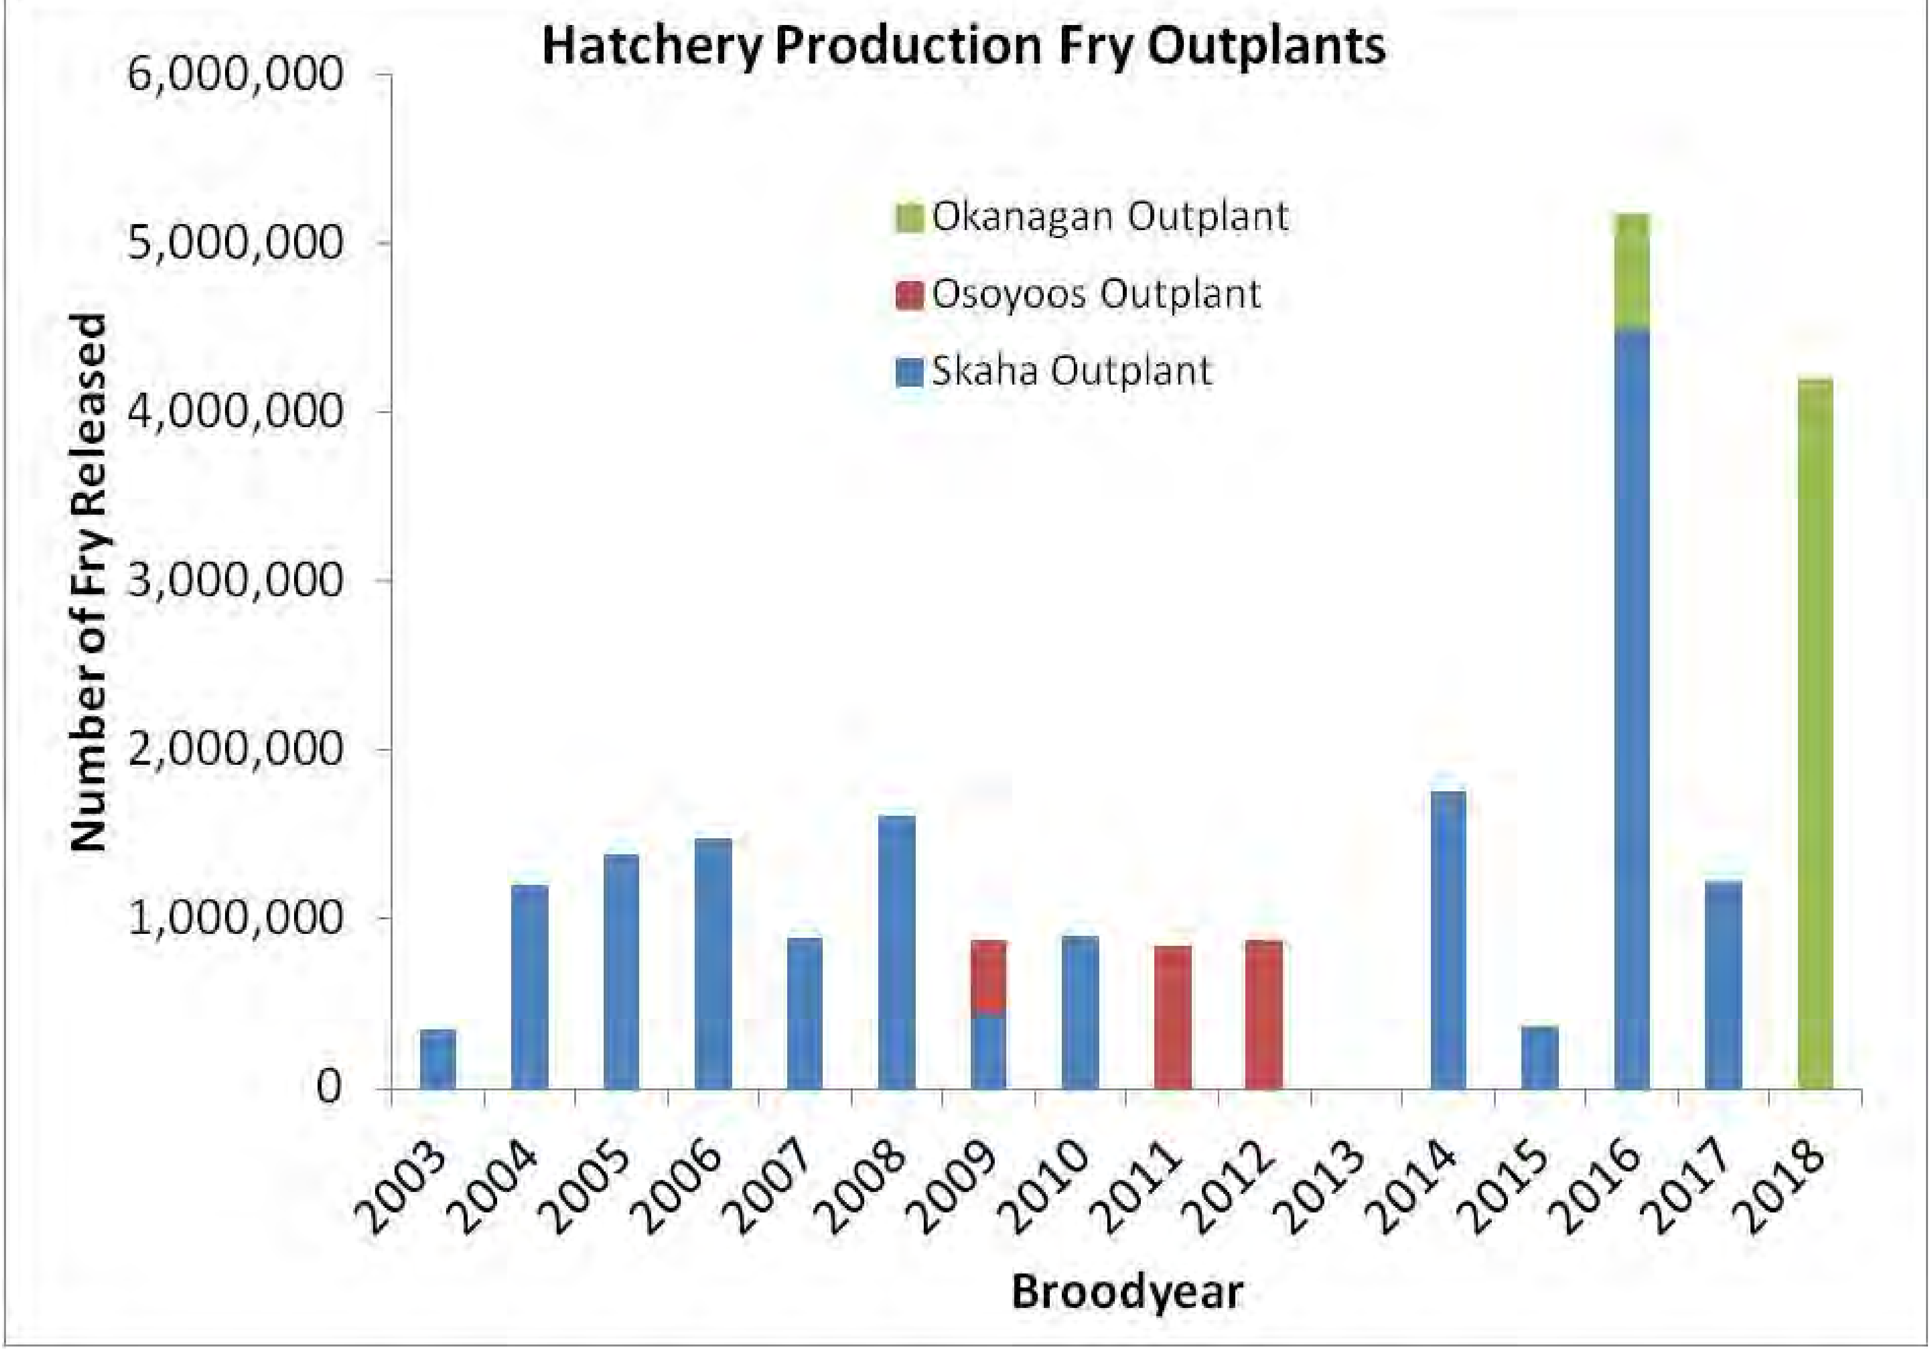
- Archiving milt for future years (contingency). Typically use 20 male samples from four years previous for fertilization; same parental stock cycle. (Not done in 2019).
- Continue experimenting with more natural release strategy (March, April, May)

Hatchery Operation – cont'd

- High number of 3-year olds – total 30 females (6.8 %)
- 32 females from Penticton Channel (6.2% of total egg take)
- Jacks and Jills were trying to enter hatchery effluent pipe

•All brood females were transported to hatchery for spawning (improved logistics)

- All males live squeezed and released in Oliver.
- Streamline for large 2020 return



Hatchery Production Fry Outplants
Number of Fry Released
6,000,000
5,000,000

	Osoyoos	Skaha	Combined
Survival (release to Bonneville)	0.34	0.24	0.28
Travel Time (days)	30.0	27.1	29.1

- On-going improvements in methods – reduced handling to improve survival
- Total PIT tagged = 9,082;
  - Osoyoos = 4,968
  - Skaha = 4,114

Skaha Lake Natural Production

Brood Year	Escapement (est)	Egg deposition (million)	Natural Smolts
2011	9,426	10.3	309,000
2012	8,273	9.1	270,000
2013	6,840	7.5	225,000
2014	20,916	23	690,000
2015	1,632	1.8	54,000
2016	4,016	4.4	132,000
2017	5,600	6.2	185,000*
2018	23,500	25.9*	940,000*
2019*	2,240**	2.0*	60,000*

In-Lake Monitoring Summary

- BY 2004-2017 mean hatchery survival
  - Fry to pre-smolt – 40.7% (56% lower than Osoyoos natural)
  - Egg to pre-smolt – 15.2% (102% or 3X higher than natural)

- Possibly reached Skaha L. carrying capacity
  - Potential density dependence: growth suppression in 2018, no survival reduction detected.
  - May change annually depending on conditions (nutrients & production, flushing, natural SK/KO escapement, Lake Whitefish)
  - Possible optimal/maximum loading density for hatchery fry

- Various fry release scenarios based on thermal marks.
  - Range 500,000 – 4.2 million in Skaha
  - 2 – 3 million hatchery fry would achieve same level as BY 2016 (approximately 2000 SK fry/ha, including wild)

- Skaha Lake kokanee stock is better than pre-treatment
  - Escapement 770-20,000 (pre) vs. 12,000-98,000 (post)
  - 2017 in-lake biomass was highest in 12 years
  - 2-3 year old KO have the greatest impact on zooplankton

Lab development

- Molecular testing qPCR
  - Real time PCR for IHN and BKD
  - ELISA for BKD
  - eDNA for N. Pike, Chinook, mussels (invasive and endangered)
- PRV disease testing for fish farms
- Chinook biosampling initiatives
- Northern Pike aging
- Water Quality Monitoring
- Macroinvertebrates
  - CABIN and EEM method
  - Partnership with certified taxonomists

Okanagan Basin Salmon Restoration Sub-Committee

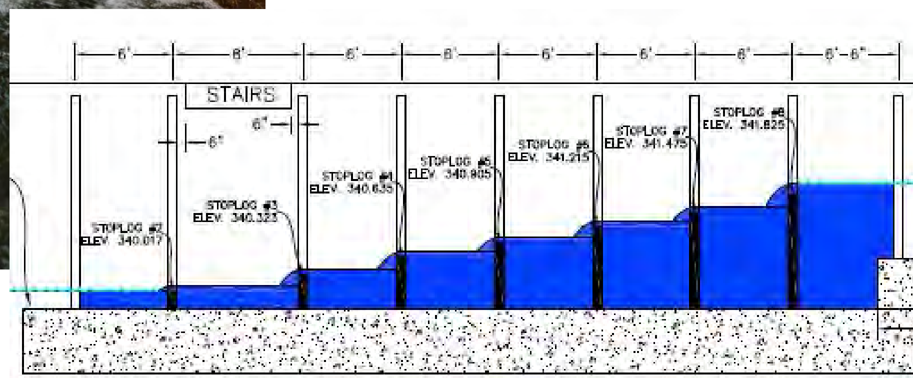
- New mandate of the Skaha Re-Introduction Sub-Committee
- Incorporates all lakes and tributaries in Okanagan Watershed
- Salmonids (Sockeye/kokanee, Chinook, Rainbow/steelhead)
- Invasives and Species at Risk
- Ecosystem approach
- Currently drafting an Okanagan Lake Monitoring and Evaluation Plan for the Basin
- 4.2 million Sockeye fry released in Okanagan Lake (ITC approval, COBTWG Letter of Support)
    - Monitor fry using Fall/ Winter ATS
    - Smolt migration in 2020
    - Returning adults
    - Residualization

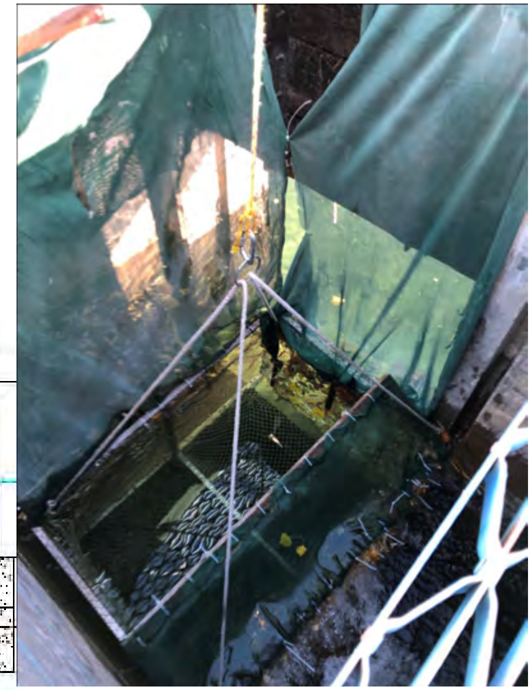
Okanagan Lake Program

- DFO has approved long-term hatchery Sockeye outplants, contingent on an M&E program
  - M&E Plan is being finalized
  - Okanagan Basin Salmon Recovery Sub-Committee
  - Working towards Salmon passage at Penticton Dam (proposed trap and tag 100 adults in October 2019)

- Hatchery stocking:
  - 2016 – 9,994
  - 2017 – 683,656
  - 2018 – 10,110
  - 2019 – 4,200,000
- Potential for high natural production; exceed Skaha and Osoyoos combined

Penticton Dam (Okanagan Lake Outlet) Passage





- First passage since 1953
- Similar to Skaha Lake Dam
- Testing hydraulics, jump efficiency, attraction flow for 2020
- No SK captured, likely missed migration window
    - 2 mid-sized Rainbow Trout in net pen

•Identify improvements for future funding (e.g. automated gates, capture platform, PIT antenna)

limləmt

Appendix C
Habitat Conservation Plan Tributary Committees 2019 Meeting Minutes

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 10 January 2019

Members Present: Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Tom Kahler (Douglas PUD), Brandon Rogers (Yakama Nation), Catherine Willard (Chelan PUD), and Tracy Hillman (Committees Chair).

Members Absent: Kate Terrell (USFWS) and Justin Yeager (NOAA Fisheries)[1].

Others Present: Becky Gallaher (Tributary Project Coordinator), Steve Kolk (U.S. Bureau of Reclamation), Mike McAllister (Inter-Fluve), and Hans Smith, Chris Clemons, and Jason Breidert (Yakama Nation).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 10 January 2019 from 9:00 am to 12:45 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with the following changes:

- Added East Fork Mission Creek Restoration Project discussion.
- Added Monitoring Side Channel Design Project discussion.
- Added Icicle Boulder Field Fish Passage Project discussion.
- Added Barkley Irrigation – Under Pressure Project Time Extension.
- Deleted Burns-Garrity Seasonal Side Channel Project: The project sponsor (Cascade Columbia Fisheries Enhancement Group) did not submit the proposal.

II. Review and Approval of Meeting Minutes

Tributary Committees members present reviewed and approved the 13 December 2018 meeting notes. Tracy will secure approval from Kate and Justin, who were not present because of the federal government furlough.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

[1] Kate and Justin will provide their input and votes on decision item following the meeting.

- Barkley Irrigation – Under Pressure Project – The sponsor (Trout Unlimited; TU) reported that Phase 1 of construction is complete. A contract has been issued for Phase 2 and the sponsor released a bid solicitation for Phase 3.
- Icicle Boulder Field Project – The sponsor (TU) reported they continue to prepare a potential bid solicitation, which they hope to release in spring 2019. They also worked with Washington Department of Fish and Wildlife (WDFW) and the City of Leavenworth to address the fish screen costs. The City agreed to remove several features that were originally added to improve future water management. These features were unnecessary for fish screen function.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – This project is complete. The sponsor (WDFW) submitted the third-year monitoring report, which was uploaded to the Extranet Site.
- Burns-Garrity Design Project – The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) will submit a new project application that proposes to develop a seasonal side channel rather than a perennial side channel.
- Beaver Fever Project – The sponsor (TU) continues to work with the Forest Service on installation of beaver dam analogs (BDAs) in Potato and Roaring creeks.
- Methow Basin Barrier Diversion Assessment Project – The sponsor (CCFEG) reported no new activity on this project. The sponsor plans to resume surveys next summer.
- Derby Creek Fish Passage Project – The sponsor (CCFEG) reported they are currently reviewing the preliminary design. A regulatory site visit is planned for mid-January.
- Chiwawa Nutrient Enhancement Project – The sponsor (CCFEG) reported they continue to do weekly water-quality sampling. Because of snowfall, sampling has been limited to the lower site at the Chiwawa River Road Bridge.
- Monitor Side Channel Design Project – The sponsor (Chelan County Natural Resources Department; CCNRD) reported they held a meeting on 19 December with Natural Systems Design (NSD) and members of the TC to discuss initial designs. NSD is developing preliminary designs.

IV. Project Collaboration

Steve Kolk (Bureau of Reclamation; BOR) described their (BOR) vision for habitat restoration work in the Upper Columbia (see Attachment 1). He talked about the evolution of restoration efforts in the Upper Columbia and concluded that we are now at a point where we need to implement larger, more complex and expensive projects than we have in the past (what he called “mega” projects). He added that most of the easier, smaller projects (he called these “micro” projects) have been implemented. Steve presented a flow diagram showing the framework for implementing both “micro” and “mega” projects. Under the “mega” approach, BOR will no longer sole source projects but rather allow implementers to bid on larger projects. Steve believes competition will increase the cost-effectiveness of projects.

The approach begins with BOR teaming with a funding entity (the team is referred to as the Development Team). BOR believes engaging a funding partner early in the process will have the highest likelihood of success. The Development Team will work together to identify and scope high priority projects in high priority areas. Once identified, BOR will use their resources to develop preliminary, draft, and final designs. Project sponsors are selected (e.g., through competitive bids) and they implement the projects. This scope-driven approach should reduce costs and increase certainty of success.

Steve explained that BOR brings project management and technical expertise to the process. Regarding project management, BOR will identify roles and responsibilities, provide stakeholder management, and help identify “Go” or “No Go” decision points. BOR has numerous technical partners including support from their Technical Service Center. Steve said the BOR has identified a few high-priority projects in the Upper Columbia including actions on the Upper Wenatchee, in Peshastin Creek, the Sugar Levee, and possible passage at natural barriers (e.g., upper Nason Creek and Upper Little Wenatchee River). These projects are consistent with potential projects identified earlier by the Tributary Committees. The Committees will continue to discuss teaming opportunities with BOR and identification of high-priority projects.

V. Time Extension Request

Barkley Irrigation Company – Under Pressure Project

The Rock Island Tributary Committee received a time extension request from Trout Unlimited on the Barkley Irrigation Company – Under Pressure Project. Because of the size and complexity of the project, and the time needed to complete the project, the sponsor asked to extend the completion date from 31 December 2018 to 31 December 2019. After review and discussion, members present from the Rock Island Tributary Committee approved the time extension. Tracy will secure input from Kate and Justin once the furlough ends.

VI. General Salmon Habitat Program Application

Icicle Creek Fish Passage – Wild Fish to Wilderness Project

In December, the Committees received a General Salmon Habitat Program proposal from Trout Unlimited titled: *Icicle Creek Fish Passage – Wild Fish to Wilderness Project*. The purpose of the project is to enhance fish passage at the Boulder Field (RM 5.6) on Icicle Creek and thereby provide access to more than 23 miles of high-quality habitat. This will be accomplished by creating a 160-foot fishway (14% slope, step-pool channel) along the left bank. This project is likely to have a large positive effect on steelhead abundance, productivity, and spatial structure. The total cost of the project is $2,275,000. The sponsor requested $375,000 from HCP Plan Species Account Funds. The amount requested from the Tributary Committees would be in addition to the $250,000 approved by the Rock Island Tributary Committee in 2015. In December, all members except the Colville Confederated Tribes (CCT) approved funding for the project. The CCT asked for additional time before providing their vote on the project. During the January meeting, CCT approved funding for the project provided a statement of agreement (SOA) regarding anadromous fish management in the Icicle watershed is signed by the Yakama Nation (YN), CCT, WDFW, NOAA Fisheries, and USFWS. Approval by YN was also contingent on approval of the SOA. The Rock Island Tributary Committee considers this proposal a budget amendment. Thus, the total amount approved by the Rock Island Tributary Committee for this project is $625,000. Justin and Kate provided input on this project in December.

Upper Kahler Stream and Floodplain Enhancement Project

In December, the Committees received a General Salmon Habitat Program proposal from the Yakama Nation titled: *Upper Kahler Stream and Floodplain Enhancement Project*. The purpose of the project is to reduce the risk of an avulsion near RM 8.6 on Nason Creek by constructing a large, buried, log jam at the upstream inlet of the developing avulsion channel and filling the avulsion channel with large substrate. The project will also construct three additional buried bank jams and enhance fish habitat at the downstream end of the avulsion channel. In addition to minimizing the risk of an avulsion, the proposed placement of wood and enhancement of the downstream end of the avulsion channel will improve spring Chinook and steelhead habitat. The total cost of the project is $482,500. The sponsor requested $231,500 from HCP Plan Species Account Funds. In November, the Tributary Committees elected to not fund this project as currently designed but invited the project sponsor to give a presentation to the Committees during a future meeting explaining the design of the project.

During the January meeting, YN and their consultant, Mike McAllister (Inter-Fluve), gave a presentation on the design of the Upper Kahler Stream and Floodplain Enhancement Project (see Attachment 2). They walked through the design process and why certain elements identified by the Tributary Committees were or were not included in the final design. They stated that the current landowner has removed riparian vegetation around the avulsion channel and that is why there will be no disturbance to riparian vegetation during the filling of the avulsion channel. The Committees questioned the need for filling the avulsion channel. They recommended simply adding large wood and a few boulders that will help trap sediments and fill the avulsion channel naturally.

With regard to the large logjam at the upstream end of the avulsion channel, YN stated the structure serves two purposes; it provides fish habitat and reduces erosion of the bank where an avulsion is most likely to occur. The structure is designed to allow higher flows to spread out onto the floodplain. Thus, it still provides floodplain connectivity, but without the concern of an imminent avulsion. The other large-wood structures are designed to provide fish habitat (i.e., pools and cover, both of which are limiting in this reach of Nason Creek).

Following the presentation, the YN recused themselves and the Committees discussed the project. The Committees struggled with filling the avulsion channel with large sediments. They believe adding wood and a few boulders in the avulsion channel will help trap smaller sediments and fill the channel naturally. They elected to table a decision on this project until Justin and Kate have an opportunity to provide feedback on the project. Once the furlough ends, Tracy will schedule a conference call to discuss this project with all members.

Stormy Project Area "A" Stream and Floodplain Enhancement Project

In December, the Committees received a General Salmon Habitat Program proposal from the Yakama Nation titled: *Stormy Project Area "A" Stream and Floodplain Enhancement Project*. The purpose of the project is to maintain salmon and steelhead spawning habitat within the middle Entiat River, improve mainstem juvenile rearing and adult holding habitat, and improve off-channel juvenile rearing habitat. This will be accomplished by constructing ten mainstem log structures and two perennial side channels. One side channel will be 200 feet long; the other will be 2,500 feet long. Large wood will also be placed throughout the side channels. The total cost of the project is $1,652,218.15. The sponsor requested $1,140,968.15 from HCP Plan Species Account Funds. In December, the Tributary Committees elected to not fund this project as currently designed but invited the project sponsor to give a presentation to the Committees during a future meeting explaining the design of the project.

During the January meeting, YN and their consultant, Mike McAllister, gave a presentation on the design of the Upper Kahler Stream and Floodplain Enhancement Project (see Attachment 3). They explained that the existing side channel that the Committees wanted reconnected is too high on the floodplain to connect with the river and has zero gradient. They would also need to mitigate for the existing network of wetlands that currently exist in the side channel. The side channel proposed by YN was designed to avoid destroying existing wetlands but nevertheless provide wetland connections at higher flows. YN showed a similar side channel project along the Chewuch River in the Methow River basin. They indicated that the side channel is used for spawning and rearing by spring Chinook salmon, coho salmon, and steelhead. YN also explained that the large wood structures proposed along the margins of the main channel are designed to provide fish habitat (pools and cover) and are not designed to stabilize banks.

The Committees asked about the possibility of elevating the bed of the main channel. This would allow floodplain reconnection without extensive floodplain excavation. YN indicated they examined the possibility of elevating the bed but found it would have unacceptable consequences to an upstream landowner, who opposed the action. Thus, they are limited to restoring the floodplain without elevating the main channel.

Following the presentation, YN recused themselves and the Committees discussed the project. The Committees appreciated the discussion on the project and they better understand the reasons for the constructed side channels and the placement of proposed large wood structures in the mainstem Entiat River. Given the presentation and discussions, members of the Committees present elected to fund the project for $1,140,968.15. They directed Tracy to secure justification from YN for the cost of excavation and mobilization. Together, these items cost nearly $600,000, which seems excessive given the spoils from excavation will be placed onsite. They also directed Tracy to secure feedback from Kate and Justin, who were not present because of the government furlough. If Justin approves the project, the Rock Island or Rocky Reach Plan Species Account will support the project.

Johnson Creek US Highway 97 Habitat Restoration Project

The Committees received a General Salmon Habitat Program proposal from Trout Unlimited titled: *Johnson Creek US Highway 97 Habitat Restoration Project*. The purpose of the project is to remove a fish passage barrier on Johnson Creek, a tributary to the Okanogan River. The project will replace the existing culvert, which is located just upstream from the town of Riverside, with a precast concrete structure that will allow passage for all life stages of Chinook salmon and steelhead at all flows. The project will allow fish access to nine miles of high-quality spawning and rearing habitat in Johnson Creek. The total cost of the project is $1,562,455.00. The sponsor requested $267,547.00 from HCP Plan Species Account Funds. Tributary Committees members present elected to fund the project. Note that Chris Fisher (CCT) recused himself from voting on this project. The Committees directed Tracy to secure feedback from Kate and Justin on this project. If approved by Justin, the Wells Plan Species Account will support the project.

VII. Review of Tributary Committees' Policies and Procedures

Policies and Procedures for Funding Projects

The Committees reviewed their Policies and Procedures document and made a minor edit to clarify language in Sections 2.0 (Funding Programs). They made no other edits or changes to the document.

Tributary Committee Operating Procedures

The Committees reviewed their operating procedures and made a formatting change to the Introduction. They made no other edits or changes to the document.

VIII. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from December and January:

   Rock Island Plan Species Account:

   - $35.00 to Clifton Larson Allen for Rock Island financial administration in December 2018.
   - $1,451.29 to Chelan PUD for Rock Island project coordination and administration during the fourth quarter of 2018.
   - $13,922.09 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project.
   - $70.66 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project.
   - $2,194.59 to Trout Unlimited for the Beaver Fever – Restoring Ecosystem Function Project.

Rocky Reach Plan Species Account:

- $35.00 to Clifton Larson Allen for Rocky Reach financial administration in December 2018.
- $878.92 to Chelan PUD for Rocky Reach project coordination and administration during the fourth quarter of 2018.
- $7,492.31 to Cascade Columbia Fisheries Enhancement Group for the Burns-Garrity Restoration Design Project.

Wells Plan Species Account:

- $427.38 to Chelan PUD for Wells project coordination and administration during the fourth quarter of 2018.

2. Catherine Willard and Tracy Hillman reported they participated on a conference call with CCNRD and their consultant to discuss designs for the Monitor Side Channel Project. Because few Rock Island Tributary Committee members participated on the call, Tracy asked the Committee if CCNRD can present the preliminary designs to the Committee during the March meeting. Members present apologized for not participating on the call and agreed to invite CCNRD to the March meeting to discuss the Monitor Side Channel designs.
3. Tracy Hillman stated that he received an email from CCNRD asking if the Committees would be interested in seeing a proposal that restores 2.8 miles of East Fork Mission Creek, which has been affected by the presence of a retired Forest Service road within the floodplain. The road is contributing large amounts of fine sediment to the channel, causing channel incision, and creating a possible fish passage barrier. The goal of the proposed project is to remove the road prism and add wood to help reconnect the floodplain. Committees members present indicated they would like to review a proposal on the proposed project.

IX. Next Steps

The next scheduled meeting of the Tributary Committees will be on Thursday, 14 March 2019 at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Attachment 2

Presentation by Mike McAllister (Inter-Fluve) on the Upper Kahler Stream and Floodplain Enhancement Project

Issues Raised by the Committees

Avulsion - why filling the avulsion channel is necessary

- The Committees understand your efforts to minimize risk of avulsion. An avulsion at this site would reduce the amount of available habitat by disconnecting the existing meander.
- However, they do not support filling the avulsion channel with large sediments.
- Rather, they believe the risk of an avulsion could be reduced by placement of wood structures within the main channel that encourage deposition at the potential site of avulsion.
- The proper placement of these structures would also divert high-energy flow away from the left bank and thereby reduce the risk of an avulsion.

Large Wood Structures - why buried bank jams are the preferred solutions in this site

- Finally, to reduce enhancement costs, they recommend the use of pilings and racked wood to improve fish habitat in the reach. These structures would replace the proposed buried bank jams at an expected reduced cost.

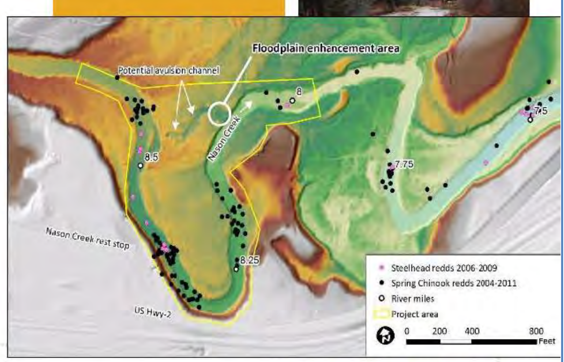
HONOR. PROTECT. RESTORE.

Project Goals

- Improve juvenile steelhead and spring Chinook rearing habitat
- Preserve existing habitat
- Increase instream complexity and alcove habitat

Objectives

- Install large wood to enhance physical habitat (e.g. increased hydraulic complexity, scour pools, gravel retention/sorting and cover)
- Preserve existing riparian vegetation and enhance riparian vegetation where practical.
- Increase high flow refuge and improve floodplain connectivity in a safe and practical manner.
- Reduce headcut risk.



HONOR. PROTECT. RESTORE. 3

Existing Condition

Natural Conditions in reach?

- Wood deficit
- Homes, roads, bridges, highway, railroad, power lines, riprap

Natural Conditions at site?

- Landowner has removed understory riparian shrubs. Ground is smooth (Low roughness). Overbank flow is swift.
- Lack of dense root structures to bind soils. Easily eroded.

Attachment 3

Presentation by Mike McAllister (Inter-Fluve) on the Stormy Project Area "A" Stream and Floodplain Enhancement Project

Issues Raised by the Committees

Large Wood Structures

- On several occasions in the past the Committees reviewed similar designs prepared by the Bureau of Reclamation (BOR) for the Entiat River.
- During the reviews, the Committees consistently said they supported removing levees and enhancing the Cottonwood Flats site. they do not support the proposed large wood projects, many of which appeared to be designed to stabilize banks (recall that the Independent Scientific Advisory Board also questioned these large wood projects).
- There are several large wood elements in the Stormy Project Area "A" proposal that are similar to elements in the BOR designs. As with the BOR designs, the Committees do not support these structures identified in the Stormy Project Area "A" proposal.

Side Channel

- That said, the Committees do support the activation of the longer side channel (not the excavated channel) on river right. The Committees believe that activating the longer side channel will provide greater biological benefit than the excavated channel.
- The feasibility and cost effectiveness of activating the longer side channel is unclear given the need for wetland mitigation; however, the Committees recommend that this action be explored.

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 14 March 2019

Members Present: Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Tom Kahler (Douglas PUD), Brandon Rogers (Yakama Nation), Kate Terrell (USFWS), Catherine Willard (Chelan PUD), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Others Present: Becky Gallaher (Tributary Project Coordinator); Mike McAllister (Inter-Fluve); Hans Smith, Chris Clemons, and Jason Breidert (Yakama Nation); Erin McKay (Chelan County Natural Resources Department); Mike Kane (Kane Natural Resources); and John Soden and Nic Truscott (Natural Systems Design).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 14 March 2019 from 8:30 am to 1:00 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with the following changes:

- Added review of the East Fork Mission Creek Floodplain Restoration Project Proposal.
- Added review of the 2019 Eightmile Creek Fisheries Assessment Project Proposal.
- Added Icicle Screening Projects Update.

II. Review and Approval of Meeting Minutes

Tributary Committees members reviewed and approved the 10 January 2019 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- Barkley Irrigation – Under Pressure Project – The sponsor (Trout Unlimited; TU) did not provide an update for this month.
- Icicle Boulder Field Project – The sponsor (TU) did not provide an update for this month.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – This project is complete. The sponsor (WDFW) will provide the next annual report on 31 December 2019.
- Burns-Garrity Design Project – The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) reported they are not working on designs at this time.

- Beaver Fever Project – The sponsor (TU) did not provide an update for this month.
- Methow Basin Barrier Diversion Assessment Project – The sponsor (CCFEG) did not provide an update for this month.
- Derby Creek Fish Passage Project – The sponsor (CCFEG) reported they have begun the permitting process.
- Chiwawa Nutrient Enhancement Project – The sponsor (CCFEG) reported that they conducted no field work in February. The sponsor submitted the 2018 annual report, which was uploaded to the Extranet site.
- Monitor Side Channel Design Project – The sponsor (Chelan County Natural Resources Department; CCNRD) reported they hired Natural Systems Design (NSD) and they are currently working on hydraulic modeling. They will present those results to the Committee today.
- Peshastin Creek Environmental Site Assessment Project – The sponsor (CCNRD) reported they met with the landowners and are in the process of obtaining written landowner agreements.
- Entiat Fish Passage and Barrier Assessment Project – The sponsor (CCFEG) reported they are coordinating with Cascadia Conservation District on landowner outreach in the Entiat River basin.
- Twisp River Floodplain Left Bank Spring-fed Alcove Restoration Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported they have started the cultural resources process and have drafted landowner agreements.

IV. General Salmon Habitat Program Applications

Upper Kahler Stream and Floodplain Enhancement Project

In December, the Committees received a General Salmon Habitat Program proposal from the Yakama Nation (YN) titled: *Upper Kahler Stream and Floodplain Enhancement Project*. The purpose of the project is to reduce the risk of an avulsion near RM 8.6 on Nason Creek by constructing a large, buried, log jam at the upstream inlet of the developing avulsion channel and filling the avulsion channel with large substrate. The project will also construct three additional buried bank jams and enhance fish habitat at the downstream end of the avulsion channel. In addition to minimizing the risk of an avulsion, the proposed placement of wood and enhancement of the downstream end of the avulsion channel will improve spring Chinook and steelhead habitat. The total cost of the project was $482,500. The sponsor requested $231,500 from HCP Plan Species Account Funds. In November, the Tributary Committees elected to not fund this project as currently designed but invited the project sponsor to give a presentation to the Committees during a future meeting explaining the design of the project.

In January, YN and their consultant, Mike McAllister (Inter-Fluve), gave a presentation on the design of the Upper Kahler Stream and Floodplain Enhancement Project. They walked through the design process and why certain elements identified by the Tributary Committees were or were not included in the final design. At that time, the Committees questioned the need for filling the avulsion channel and recommended simply adding large wood and a few boulders that will help trap sediments and fill the avulsion channel naturally.

On 26 February, YN submitted a response to the Committees concern about filling the avulsion channel with sediments. The YN response identified three alternatives (not including the original proposed action) that include the use of wood: wood only alternative at a cost of $234,600, wood and fill alternative at a cost of $211,550, and a new fill alternative at a cost of $194,800. YN noted these alternatives may provide as much certainty in preventing an avulsion as the YN preferred action. The response noted that all alternatives must prevent a drop into the avulsion channel and interrupt headward erosion and growth of the avulsion channel. The response also pointed out that the landowner has expressed opposition to using large wood on his property where it is visible from his house.

During the meeting, YN and their consultant (Mike McAllister) described the three alternatives and their associated costs. Members of the committees appreciated the identification of alternatives but continued to struggle with filling the avulsion channel. They asked if the landowner would be willing to sign an agreement stating that the landowner cannot alter or affect the project for at least 20 years. YN did not know if the landowner would agree to those terms. Following discussion, Brandon recused himself from the meeting and members voted on the project. Given that members are opposed to floodplain fill and were concerned the landowner would not sign an agreement forbidding the landowner from altering the site for at least 20 years, the Rock Island Tributary Committee agreed to fund the large wood structures within Nason Creek (i.e., upper log structure site 1, lower log structure site 1, log structure site 3, and log structure site 4). They will not fund any actions to fill the avulsion channel. They asked YN to provide a detailed budget for the construction of the large wood structures within Nason Creek.

Stormy Project Area "A" Stream and Floodplain Enhancement Project

In December, the Committees received a General Salmon Habitat Program proposal from YN titled: *Stormy Project Area "A" Stream and Floodplain Enhancement Project*. The purpose of the project is to maintain salmon and steelhead spawning habitat within the middle Entiat River, improve mainstem juvenile rearing and adult holding habitat, and improve off-channel juvenile rearing habitat. This will be accomplished by constructing ten mainstem log structures and two perennial side channels. One side channel will be 200 feet long; the other will be 2,500 feet long. Large wood will also be placed throughout the side channels. The total cost of the project was $1,652,218.15. The sponsor requested $1,140,968.15 from HCP Plan Species Account Funds. In December, the Tributary Committees elected to not fund this project as currently designed but invited the project sponsor to give a presentation to the Committees during a future meeting explaining the design of the project.

During the January meeting, YN and their consultant, Mike McAllister, gave a presentation on the design of the Stormy Project Area A Project. They explained that the existing side channel the Committees wanted reconnected is too high on the floodplain to connect with the river and has zero gradient. They would also need to mitigate for the existing network of wetlands that currently exist in the side channel. The side channel proposed by YN was designed to avoid destroying existing wetlands but nevertheless provide wetland connections at higher flows. YN also explained that the large wood structures proposed along the margins of the main channel are designed to provide fish habitat (pools and cover) and are not designed to stabilize banks. At that time, members present supported the project but needed feedback from their federal colleagues (Kate and Justin), who were furloughed.

Following the furlough, members discussed the project with Kate and Justin. Based on that discussion, members agreed to support the proposed actions on river right (i.e., excavation of the 2,500-ft perennial side channel) and the 200-ft side channel on river left, including the apex jams used to control flows into the side channels. Because of the overall cost of the proposed project, they did not support the installation of the other mainstem log structures. In addition, they believed some of the mainstem log structures will have limited biological benefit because they do not interact with the water at lower flows and therefore will not provide important habitat for summer and winter parr. They recommended that YN seek a cost share for the implementation of the mainstem log structures.

In February, YN submitted a revised proposal to the Committees that included an updated itemized budget for the construction of the perennial side channels and apex jams associated with the side channels. The total cost of the project was $1,564,211.15. The sponsor requested $823,161.15 from HCP Plan Species Account Funds. ***The Rocky Reach Tributary Committee approved $823,161.15 for the project.***

V. Small Project Applications

East Fork Mission Creek Floodplain Restoration Project

The Committees received a Small Project proposal from Chelan County Natural Resource Department (CCNRD) titled: *East Fork Mission Creek Floodplain Restoration Project*. The purpose of this project is to develop permit-ready designs that will result in improved base flows in the Mission Creek watershed by reconnecting floodplain in a severely incised system and improve habitat for steelhead. This will be accomplished by removing an eroding road prism located within the floodplain, adding in-stream wood, and addressing potential passage barriers. The project is located along a 2.8 mile stretch of East Fork Mission Creek in the upper Mission Creek watershed. The total cost of the project is $96,169. The sponsor requested $74,669 from HCP Plan Species Account Funds.

After careful review, the Committees were unable to make a funding decision due to uncertainty about the status of the road closure and they need more information. The proposal states, "Rd 7100 is permanently closed to motorized vehicles and was formally abandoned in 2013…" During the meeting, however, the project sponsor indicated the statement in the proposal was incorrect. Therefore, the Committees asked CCNRD to provide clarification on the closure of the road. Before the Committees can make a funding decision on this project, they need to know if the Forest Service has permanently closed the road.

2019 Eightmile Creek Fisheries Assessment Project

The Committees received a Small Project proposal from Washington Department of Fish and Wildlife (WDFW) titled: *2019 Eightmile Creek Fisheries Assessment Project*. The purpose of this project is to assess the status of fish within Eightmile Creek, a tributary to the Chewuch River in the Methow River basin. These data will be used to determine a strategy for removing brook trout and restoring native salmonid production to 21 km of stream. Currently, a fish passage barrier near the mouth of Eightmile Creek precludes steelhead (and bull trout) from migrating into the stream. Because YN is looking to remove the barrier, managers want information on species composition, fish abundance, stream flows, and temperatures within Eightmile Creek. In addition, they propose to collect tissue samples from bull trout and *O. mykiss* collected within Eightmile Creek to determine their genetic composition. These data are needed to determine a strategy for removing brook trout, if necessary. The total cost of the project is $67,200. The sponsor requested the full amount from HCP Plan Species Account Funds.

After careful review, the Committees were unable to make a funding decision. They identified the following concerns with the project:

- There is no management plan that clearly identifies decision rules for determining which strategy would be selected for removing brook trout. That is, after assessments are complete, how will managers use the data to determine whether to use electrofishing, piscicides, or other brook trout removal techniques, or to decide that no brook trout removal is necessary?
- Rather than use snorkeling to conduct assessments, the sponsor should consider using electrofishing. Complete census surveys with electrofishing gear can be used to provide data on species richness and abundance and can be used to remove brook trout during the surveys. Thus, the sponsor would complete both objectives during the surveys; assessments (including collection of tissue samples for genetics analysis) and brook trout removal. Additional electrofishing surveys may be needed to reduce brook trout numbers to a level that supports successful steelhead colonization (see Thompson and Rahel 1996; Buktenica et al. 2013)[1].

---

[1] Thompson, P. D. and F. J. Rahel. 1996. Evaluation of depletion-removal electrofishing of brook trout in small Rocky Mountain Streams. North American Journal of Fisheries Management 16:332-339.
Buktenica, M. W., D. K. Hering, S. F. Girdner, B. D. Mahoney, and B. D. Rosenlund. 2013. Eradication of nonnative brook trout with electrofishing and antimycin-A and the response of a remnant bull trout population. North American Journal of Fisheries Management 33:117-129.

- The sponsor needs to indicate whether labor rates and other budget items include overhead.
- Finally, Plan Species Account Funds are not to be used to purchase equipment (e.g., snorkel equipment and water temperature loggers). This is because the Committees do not want to own and store equipment purchased with Plan Species Account Funds. However, funds can be used to rent equipment.

If the sponsor can address these concerns, the Committees will review a revised proposal.

VI. Update by CCNRD on the Monitor Side Channel Restoration Design Project

CCNRD (Erin McKay) and their consultants (Mike Kane with Kane Natural Resources and John Soden and Nic Truscott with Natural Systems Design) provided an update on the Monitor Side Channel Restoration Design Project. As background, they described the goals and objectives of the project and identified design challenges and constraints. Some of the challenges associated with this project include recreational issues, PUD powerlines, lots of infrastructure (homes), and identifying actions that will not affect the opening to the side channel. They also provided results from their hydraulic modeling work, which included RiverFlow 2D and topobathymetric LiDAR analysis and model calibration. They showed how velocities and depths change within the side channel under different flow scenarios. They also described sediment dynamics within the channel under different flows.

They presented conceptual designs that include boulder clusters, bank ELJs, weir logs, and willow trenches. They identified conceptual design alternatives noting they are considering a light touch in the upper reach of the side channel, a more aggressive approach in the middle reach, and a moderate tough in the lower reach. In the upper reach, where the channel is more confined and higher gradient, they are looking mostly at placement of boulder clusters and perhaps a few bank ELJs anchored with boulders. Within the middle reach, which is less confined, wide, and lower gradient, they are proposing bank and log weirs to create a narrower, meandering channel. In the lower reach, they propose to use weir logs and a few bank logs. The goal in the lower reach is to avoid actions that will encourage deposition at the outlet of the side channel.

Members provided feedback on the proposed alternatives. In general, they support the boulder clusters in the upper reach and recommended additional bank structures in the middle reach. They also supported more log weirs in the middle and lower reaches. Finally, they would like the project designed so it will be no more than $200,000 to construct. CCNRD and their consultants will continue working on the designs and will provide additional updates to the Committees in the near future.

VII. Review of Draft SOA

On 25 February, YN submitted a draft Statement of Agreement (SOA) to the Committees for review (see Attachment 1). Brandon Rogers said the purpose of the draft SOA is to provide a basis for decision making in the HCPs Tributary Committees. He indicated the SOA is draft and asked members to review and discuss it, edit it as necessary, and vote on it during the April meeting. Justin Yeager asked what precipitated the need for an SOA on decision making. Brandon responded the “NO” vote on the Scaffold Camp Acquisition #2 Project and the fact that the Committees have no clearly defined criteria for evaluating project proposals. Chris Fisher stated CCT cannot support the draft SOA nor will they support an SOA that will take away their right to prevent the YN from owning land in the Upper Columbia River basin. Jeremy Cram noted the language in the draft SOA is too strong and would force the Committees to vote “YES” on any project that has biological benefit. He said it appears to take way the Committees ability to require cost shares, to save money for future projects, and to reject projects based on a sponsor’s ability to implement the project. He added it places too much emphasis on cost-benefit relationships. Others agreed and said it takes away rights to reject projects based on criteria that may not be included in the draft SOA.

Tom Kahler reminded members that funding decisions require unanimous approval of the Committees (as described in HCPs), affording each member discretionary rights when reviewing and voting on project proposals. Tom provided examples within other HCP committees where parties have exercised this right and stated that Douglas PUD could not approve any agreement that would limit those discretionary rights. Furthermore, editing the draft SOA to preserve the discretionary voting rights of signatory parties would result in a very complicated document that would no longer fulfill the intent of YN in preparing the SOA. Catherine Willard pointed members to Section 9.4 of the Rock Island HCP, which states voting members "shall use their best efforts to exercise their rights and authority under statutes, regulations, and treaties, in a manner that allows the goals and objectives of the HCP Agreement to be fulfilled."

Kate Terrell and Justin asked why an SOA is necessary. The Committees have made funding decisions and justified those decisions for several years. Brandon responded that without some side boards, the Committees can make decisions based on anything they want, and these decisions may have nothing to do with what is best for the resource. Catherine again reminded members of the language in the HCPs. Chris commented that except for the Scaffold Camp Acquisition Project (and a YN protection project that was submitted through the PRCC Habitat Subcommittee), he has always voted based on what he believes is best for the resource. He said he can do nothing about Tribal politics and the issues between CCT and YN cannot be resolved within the HCP Committees.

Kate asked, given that CCT cannot support an SOA that takes away their right to prevent the YN from owning land within the Methow River basin, what is YN trying to accomplish with the draft SOA? Brandon stated that the SOA is less about the issues between the tribes and more about how the Tributary Committees make funding decisions. To that end, YN wants clear, transparent criteria that focus funding decisions on what is best for the resource. Kate asked what if the SOA is not approved. Brandon said YN will consider disputing the decision and they are also evaluating other options.

Tracy Hillman reminded the Committees that they directed him to identify possible criteria for evaluating project proposals (see Attachment 2). He reviewed those criteria with the Committees and asked if these provide the clarity and transparency the Committees desire. He added that these could be appended to an SOA or added to the Committees' Policies and Procedures for Funding Projects document (Section 5). Tracy also noted that YN is not the only party who has requested evaluation criteria. Others have as well, and Tracy said the criteria will help him prepare responses to project sponsors. Members liked the idea of having transparent criteria and Kate noted that she used the criteria when evaluating the Eightmile Creek Fisheries Assessment Project. She said the criteria were very useful and were consistent with how she has evaluated projects in the past.

Members discussed the idea of updating Section 5 in the Policies and Procedures for Funding Projects. Some members believe this would eliminate the need for an SOA. Kate and Jeremy noted this would allow the Committees to review and update evaluation criteria annually or more frequently if necessary. Brandon said he will discuss this internally, but still wants the Committees to review and edit (if necessary) the draft SOA. He said the YN will ask for a vote on the draft SOA (or edited version) during the April meeting.

Members will review and edit, if necessary, the draft SOA and be prepared to discuss it and vote on it during the April meeting. In addition, Tracy will recast the evaluation criteria, so they fit within the Policies and Procedures for Funding Projects document.

VIII. Review of Draft Wells HCP Tributary Committee Action Plan

On 17 January, Douglas PUD provided the Wells Committees with the Draft Wells HCP Tributary Committee Action Plan for 2019 for a 30-day review. Members reviewed the plan and CCT provided minor edits, which were incorporated into the plan. No other edits or comments were provided.

IX. Review of Draft Rock Island and Rocky Reach HCP Tributary Committees Action Plans

On 11 February, Chelan PUD provided the Rocky Reach and Rock Island Committees with the Draft Rocky Reach and Rock Island HCP Tributary Committees Action Plans for 2019 for a 30-day review. Members reviewed the plans and had no comments or edits.

X. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from February and March:

   Rock Island Plan Species Account:

   - $77.00 to Clifton Larson Allen for Rock Island financial administration in January 2019.
   - $35.00 to Clifton Larson Allen for Rock Island financial administration in February 2019.
   - $6,019.24 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project (for work in January).
   - $5,992.22 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project (for work in February).
   - $170.55 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project (for work in November and December 2018).
   - $583.14 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project (for work in January and February).
   - $985.20 to Chelan County Treasurer for the Monitor Side Channel Design Project (for work in December 2018).
   - $76.67 to Chelan County Treasurer for the Monitor Side Channel Design Project (for work in January).
   - $1,171.74 to Chelan County Treasurer for the Monitor Side Channel Design Project (for work in February).

   Rocky Reach Plan Species Account:

   - $77.00 to Clifton Larson Allen for Rocky Reach financial administration in January 2019.
   - $35.00 to Clifton Larson Allen for Rocky Reach financial administration in February 2019.
   - $142.73 to Chelan County Treasurer for the Peshastin Creek RM 8.8 Channel Reconnection – Environmental Site Assessment Project (for work in January).
   - $556.50 to Chelan County Treasurer for the Peshastin Creek RM 8.8 Channel Reconnection – Environmental Site Assessment Project (for work in February).
   - $44.89 to Cascade Columbia Fisheries Enhancement Group for the Burns-Garrity Restoration Design Project (for work in January).

- $406.60 to Cascade Columbia Fisheries Enhancement Group for the Entiat Basin Fish Passage and Screening Assessment Project (for work in January).

2. Becky Gallaher reported that the PUDs deposited funds into each of the Plan Species Accounts at the end of January 2019. Chelan PUD deposited $784,331 into the Rock Island Plan Species Account and $371,474 into the Rocky Reach Account. Douglas PUD deposited $284,793.79 into the Wells Account. As of March 2019, the unallocated balances within each account were $6,910,306 in the Rock Island Account, $3,215,267 in the Rocky Reach Account, and $1,813,698 in the Wells Account. Thus, among the three accounts, there is about $11,939,271 available.
3. Tracy Hillman shared the Salmon Recovery Funding Board (SRFB) Funding Schedule with the Committees (see Attachment 3). He said draft proposals are due on 12 April. Project tours are scheduled tentatively for 9 May (Okanogan and Methow), 13 May (Wenatchee), and 14 May (Entiat). Sponsors will give presentations on 12-13 June. The Committees will evaluate the draft proposals on 13 June and decide which projects should be submitted as final proposals. Final proposals are due on 28 June. The Committees will evaluate final proposals and make funding decisions on 11 July.
4. Tracy Hillman stated that John Ferguson (Chair of the HCP Coordinating Committees) sent letters to the Confederated Tribes of the Umatilla Indian Reservation and American Rivers inquiring about their interest in participating in a meeting with members of the HCP Coordination, Hatchery, and Tributary Committees. These parties were involved in negotiating the HCPs but elected not to sign the HCPs. This is an opportunity for the Committees to provide the two parties with a progress report on implementation, as well as give them an opportunity to ask questions of the Committees members. The two entities are to provide a formal response to the invitation by 15 April 2019.
5. Jeremy Cram gave a brief update on the Icicle Screening Projects (see Attachment 4). He indicated the cost of the City of Leavenworth screen has increased significantly, primarily because of the need to redesign the structure to address concerns with frazil ice, debris, and sweeping flows. Jeremy said unforeseen expenses included discovery that power did not run past the water treatment facility, the waterline between the intake and treatment plant runs parallel to flow within the bounds of ordinary high water (the proposed design relocates that portion of the line outside of the ordinary high water and keeps horizontal bends and removal of riparian trees to a minimum but requires substantial excavation), the pipe runs through an existing settling basin that is housed in a structurally failing concrete building, and material costs have gone up dramatically since the initial budget was developed. The redesigned City of Leavenworth screen will cost about $941,500. The ask from the Tributary Committees could be about $801,500, which is about 2.3 times greater than the ask last year. Members said they would consider supporting the project for $352,545, which was equivalent to 75% of the original ask. Recall the Committees required the City of Leavenworth to contribute 25% of the total cost. Jeremy will share this information with Jennifer Novak and Jeff Dengel.
6. The Committees were unable to discuss coordination with the Bureau of Reclamation and the targeted projects. They will discuss these items during the April meeting.

XI. Next Steps

The next scheduled meeting of the Tributary Committees will be on Thursday, 11 April 2019 at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Attachment 1
Draft SOA from the Yakama Nation

Rocky Reach, Rock Island, and Wells HCP Tributary Committees
DRAFT Statement of Agreement

Basis for Decision Making in HCP Tributary Committees
February 25, 2019

Statement

The Rocky Reach, Rock Island, and Wells Habitat Conservation Plans (HCP) Tributary Committees (TCs) agree that mitigation funding decisions will be based exclusively on the merit of proposed projects (biological benefit, technical merit, feasibility, durability, and cost effectiveness) having a direct nexus to plan species, plan species habitat, or plan species management. Signatories agree not to base funding decisions on criteria other than project merit.

Background

The Wells, Rocky Reach, and Rock Island HCP Tributary Committees' Policies and Procedures for Funding Projects (January 10, 2019) describes the eligibility and review criteria for evaluating project funding decisions. Section 5 of that document specifies that project funding decisions are made on the basis of biological benefit, technical merit, feasibility, durability, and cost effectiveness. However, Section 5 does not explicitly disallow criteria unrelated to resource benefits to be introduced into decision-making. The purpose of this SOA is to clarify that the Tributary Committees intend that all funding or other decisions regarding how PUD mitigation is implemented will have a direct nexus to the expected benefits to a plan species or plan species habitat. Decision making by a signatory for reasons unrelated to mitigation benefits are not within the spirit or intent of the HCPs and will impede the operation of the Committees. Any signatory attempting to vote on the basis of criteria other than those directly related to resource impacts may abstain from 'voting'.

Attachment 2
Draft Project Evaluation Criteria

HCP Tributary Committees Project Evaluation Rubric

I. General Criteria

Target Species

Does the proposed project address HCP Plan Species (spring Chinook, summer/fall Chinook, coho, sockeye, and/or steelhead)?

Target Area

Is the proposed project located within the geographic scope of the HCPs (projects must be in the Columbia River watershed from Rock Island Dam tailrace to Chief Joseph Dam tailrace)?

II. Restoration Projects

Biological Benefit

Does the proposed project reduce the effects of primary ecological concerns (limiting factors) at the project and reach scale?

Does the proposed project address limiting life stages of Plan Species within the watershed or AU?

Is the proposed project sited within an important spawning/rearing area, or provides access to habitat that would function as important spawning/rearing habitat for Plan Species?

Does the proposed project increase freshwater survival, capacity/abundance, spatial structure, and/or diversity for Plan Species at the project or reach scale?

Technical Merit

Are the methods outlined within the proposal adequate to achieve the stated objectives?

Is the proposed project appropriately scaled and scoped?

Is the proposed project sequenced properly?

Durability

Does the proposed project promote natural stream/watershed processes that are consistent with the geomorphology of the stream?

How long will it take for the proposed project to achieve its intended response?

How long will the proposed project and its benefits persist?

Will the proposed project ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?

Are there permitting or regulatory constraints that will prevent the proposed project from being implemented?

Are there funding constraints that will prevent the project from being implemented?

Does the project sponsor have the experience, resources, and infrastructure to implement the project successfully?

Cost Effectiveness

Is the proposed project cost effective (based on the assumed benefit)?

Does the proposed project need a cost share? If so, how much?

III. Protection Projects

Biological Benefit

Is the proposed project sited within an important spawning/rearing area for Plan Species?

To what extent does the proposed project protect high-quality habitat or habitat that can be restored to high quality with appropriate restoration actions?

What would be the anticipated loss in freshwater survival, capacity, spatial structure, and/or diversity of Plan Species at the project or reach scale if the proposed area was developed (i.e., what habitat values would be lost and to what degree would that loss reduce freshwater survival and/or distribution of Plan Species at the project/reach scale)?

Technical Merit

How imminent is the threat of habitat degradation to the proposed land if the project is not implemented?

Will the landowner allow public access?

Durability

Does the proposed project protect watershed processes or important high-quality habitat in perpetuity?

Are there any conditions regarding the protection of the property that could limit the existing high-quality habitat?

Will the proposed project help ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?

Are there funding constraints that will prevent the project from being implemented?

Does the project sponsor have the experience, resources, and infrastructure to implement the project successfully?

Cost Effectiveness

Is the proposed project cost effective (e.g., based on cost per linear foot of streambank or cost per acre of riparian/floodplain habitat protected)?

Does the proposed project need a cost share? If so, how much?

IV. Design Projects

Biological Benefit

Will the proposed design lead to development of projects that reduce the effects of primary ecological concerns (limiting factors) at the project and reach scale?
Will the proposed design lead to development of projects that address limiting life stages of Plan Species within the watershed or AU?
Is the proposed design sited within an important spawning/rearing area, or will provide access to habitat that would function as important spawning/rearing habitat for Plan Species?
If the design is implemented, will it increase freshwater survival, capacity/abundance, spatial structure, and/or diversity for Plan Species at the project or reach scale?

Technical Merit

Are the methods outlined within the proposal adequate to achieve the stated objectives?
Is the proposed project appropriately scaled and scoped?
Is the proposed project sequenced properly?

Durability

Will the proposed design lead to development of projects that promote natural stream/watershed processes that are consistent with the geomorphology of the stream?
If the design is implemented, how long will it take for the proposed project to achieve its intended response?
If the design is implemented, how long will the proposed project and its benefits persist?
If the design is implemented, will the proposed project ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?
Are there permitting or regulatory constraints that will prevent the design from being implemented?
Are there funding constraints that will prevent the design from being implemented?
Does the project sponsor have the experience, resources, and infrastructure to complete the designs?

Cost Effectiveness

Is the proposed project cost effective (based on the assumed benefit)?
Does the proposed project need a cost share? If so, how much?

V. Assessment Projects

Biological Benefit

Will the proposed assessment lead to projects that reduce the effects of primary ecological concerns (limiting factors) at the project and reach scale?
Will the proposed assessment lead to projects that address limiting life stages of Plan Species within the watershed or AU?

Is the proposed assessment sited within an important spawning/rearing area, or in an area that could function as important spawning/rearing habitat for Plan Species?

Technical Merit

Are the methods outlined within the proposal adequate to achieve the stated objectives?
Is the proposed project appropriately scaled and scoped?

Durability

Will the proposed assessment lead to projects that promote natural stream/watershed processes that are consistent with the geomorphology of the stream?
Will the proposed assessment lead to projects that ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?
Are there permitting or regulatory constraints that will prevent the assessment from being implemented?
Are there funding constraints that will prevent the assessment from being implemented?
Does the project sponsor have the experience, resources, and infrastructure to complete the assessment?

Cost Effectiveness

Is the proposed project cost effective (based on the assumed benefit)?
Does the proposed project need a cost share? If so, how much?

Attachment 3
Draft SRFB Funding Schedule

UPPER COLUMBIA SRFB/TRIB DRAFT 2019 FUNDING SCHEDULE

Update on Icicle Screening Projects

IPID and City of Leavenworth Fish Screen Projects Updated Cost Estimates

To: PRCC and Tributary Committees

From: Jennifer Novak, Project Manager;
Shawn Stanley, Project Engineer;
Jeff Dengel, Icicle Working Group Liaison

Date: March 14, 2019
Re: Updated Cost Estimates for IPID and City of Leavenworth Fish Screen Projects

Concept level designs were developed and presented to the Icicle Working Group (IWG) in December 2015. In January 2016, we were given 10 calendar days to develop a design and construction estimate and proposal for Bonneville Power Administration (BPA) distributed targeted solicitation funds for the City and IPID fish screens. The original construction estimate for the City design was $410k, with an additional $25k for permitting, and $41k for construction oversight, totaling $476k. That concept was for an airburst cleaned plate screen at the point of diversion using the existing infrastructure and the disturbed footprint would be minimal. The design concept and estimate were completed prior to having a robust topographic survey, hydraulic modeling, or any input from the City.

A design contract was executed in August 2017 with BPA. Minimal work was performed on the design through the end of the year due to competing demands for staff time. The funding request submitted January 2018 utilized the previously developed scoping estimate for an airburst system. WDFW began meeting with the City of Leavenworth staff and contractors for the boulder field project monthly to develop the City's screen design from Jan 2018 – Jan 2019. Due to concerns with frazil ice, debris, and sweeping flows, it became apparent that using the existing pod infrastructure would have ongoing operational challenges. The resulting design is 700 feet downstream of the original location in a different style building over a vault 15 feet deep in the ground to tie into the City's existing water conveyance pipe. A drastically different product than originally envisioned but much better functionally overall.

Benefits of relocating the screen include:

1. Improved operational function. The screen will not need to be pulled when frazil ice is present and there will be increased sweep past the screen compared to the original design, both benefitting fish.
2. Elimination of in-water construction work minimizes impacts on water resources during the construction process, reduces complexity of work, and minimizes opportunities for fouling.
3. Enhanced access for construction and maintenance equipment with the expectation of reducing construction complexity, duration, risk, and cost.
4. Increased level of safety for maintenance personnel.
5. Reduced operational and maintenance expenses and level of effort.

When this design change was made, cost trade off assumptions were made. Anticipated reductions in cost were:

1. Elimination of a generator and compressor setup from the design.
2. Improved access for equipment eliminates vertical work with a crane and expedites prosecution of work.
3. The building housing the compressor and generator was planned to be concrete block construction to attenuate equipment noise. This would be replaced by a cheaper pre-engineered metal building since the new hydraulically operated screen would not produce the equivalent noise.
4. Elimination of in-water work removes dewatering requirement.

Those savings were assumed to be equivalent to:

1. Excavation and installation of 200 feet of pipe and
2. Excavation and construction of a vault for the screen.

Unforeseen expenses added to the budget include:

1. Discovery that power did not run past the water treatment facility. It was assumed that power extended past the City's treatment plant (last location of aerial lines) buried adjacent to the road servicing residences and buildings past the plant. Power service ends at the plant. Power had to be ran for 1,600 feet instead of being able to tie into roadside power 60 feet away from the proposed building as originally expected.
2. The waterline between the intake and treatment plant runs parallel to flow within the bounds of ordinary high water (OHW). The proposed design relocates that portion of the line outside of OHW and keeps horizontal bends and removal of riparian trees to a minimum but requires substantial excavation.
3. The above mentioned pipe runs through an existing settling basin that is housed in a structurally failing concrete building. The concrete structure is also within OHW and, for the foreseeable future, will continue to harden the bank, disintegrate into the channel, and pose a liability risk for the City. The estimated cost to remove the building and regrade the bank is $70k.
4. Materials costs have gone up dramatically since the initial budget was developed Jan 2016. Steel is up 100%, concrete has been up as much as 100%, and fuel is up 100%. There is an abundance of work available for contractors to bid on at the present time. 2012-2016 saw considerably more competition on bids and lower prices than we have in 2017-2018. Bid prices have come in 20-30% higher than they did above previous work and costs. Estimated increase in job cost, $80-130k.

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 11 April 2019

Members Present: Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Tom Kahler (Douglas PUD), Brandon Rogers (Yakama Nation), Kate Terrell (USFWS), Catherine Willard (Chelan PUD), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Others Present: Becky Gallaher (Tributary Project Coordinator), Scott Hopkins (Chelan PUD Rock Island and Rocky Reach TCs Alternate), and Steve Kolk (Bureau of Reclamation; for Sugar Levee Coordination Agenda Item).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 11 April 2019 from 8:30 am to 12:00 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with the following changes:

- Review the revised budget for the Upper Kahler Stream and Floodplain Enhancement Project.

II. Review and Approval of Meeting Minutes

Tributary Committees members reviewed and approved the 14 March 2019 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- Barkley Irrigation – Under Pressure Project – The sponsor (Trout Unlimited; TU) started work on the MVID inlet modifications and reported that pipe has been delivered to the Phase 1 staging area. Completion of Phase 1 piping is scheduled for early June.
- Icicle Boulder Field Project – The sponsor (TU) reported they continue to work through the permitting process. Ecology is cautious because there is a lot of public focus on Icicle Creek. The sponsor met with Ecology to discuss the HEC-RAS (Hydrologic Engineering Center's River Analysis System) model output and focused on model runs that were requested by Ecology. Ecology would like to better understand slope stability at the conclusion of the project and the extent to which project impacts stay within the project area. Ecology also expressed a need to understand project impacts that extend beyond the project area.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – This project is complete. The sponsor (WDFW) will provide the next annual report on 31 December 2019.

- Burns-Garrity Design Project – This project is complete. The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) will provide a final report soon.
- Beaver Fever Project – The sponsor (TU) continues to reach out to landowners in the Roaring Creek watershed.
- Methow Basin Barrier Diversion Assessment Project – The sponsor (CCFEG) did not provide an update this month.
- Derby Creek Fish Passage Project – The sponsor (CCFEG) did not provide an update this month.
- Chiwawa Nutrient Enhancement Project – The sponsor (CCFEG) reported they are coordinating with Ecology to amend the water quality permit to allow an adjustment to the treatment period and allow for minimal phosphorous exceedances in the Chiwawa.
- Monitor Side Channel Design Project – The sponsor (Chelan County Natural Resources Department; CCNRD) reported they and Natural Systems Design completed a site visit to evaluate access, locate potential structures, and gather additional data such as pebble counts.
- Peshastin Creek Environmental Site Assessment Project – The sponsor (CCNRD) did not provide an update this month.
- Entiat Fish Passage and Barrier Assessment Project – The sponsor (CCFEG) reported there was no new activity this month.
- Twisp River Floodplain Left Bank Spring-fed Alcove Restoration Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) did not provide an update this month.
- Johnson Creek Habitat Restoration Project – The sponsor (TU) did not provide an update this month.
- Cottonwood Flats Floodplain Restoration Project – The sponsor (CCNRD) did not provide an update this month.

IV. Small Project Applications

East Fork Mission Creek Floodplain Restoration Project

In March, the Committees received a Small Project proposal from Chelan County Natural Resource Department titled: *East Fork Mission Creek Floodplain Restoration Project*. The purpose of this project is to develop permit-ready designs that will result in improved base flows in the Mission Creek watershed by reconnecting floodplain in a severely incised system and improve habitat for steelhead. This will be accomplished by removing an eroding road prism located within the floodplain, adding in-stream wood, and addressing potential passage barriers. The project is located along a 2.8 mile stretch of East Fork Mission Creek in the upper Mission Creek watershed. The total cost of the project is $96,169. The sponsor requested $74,669 from HCP Plan Species Account Funds.

During the March meeting, the Committees were unable to make a funding decision. This is because they needed more information about the status of the road. The proposal stated, "Rd 7100 is permanently closed to motorized vehicles and was formally abandoned in 2013…" During the March meeting, however, the project sponsor indicated the statement in the proposal was incorrect. Therefore, the Committees asked CCNRD to provide clarification on the closure of the road.

On 27 March, CCNRD reported that the Forest Service Road is not officially and permanently closed. Based on this information, the Committees elected to not fund the project. They indicated they would reconsider the proposal if the road is officially and permanently closed, and the trail has been rerouted and constructed out of East Fork Mission Creek and the riparian area.

V. General Salmon Habitat Program Applications

Upper Kahler Stream and Floodplain Enhancement Project

During the March meeting, the Rock Island Tributary Committee agreed to fund the large wood structures within Nason Creek (i.e., upper log structure site 1, lower log structure site 1, log structure site 3, and log structure site 4). They indicated they would not fund any actions associated with filling the avulsion channel. They asked the Yakama Nation to provide a detailed budget for the construction of the four large wood structures within Nason Creek.

On 1 April, the Yakama Nation provided a revised budget for the construction of the four wood structures within Nason Creek (see Attachment 1). After review of the revised budget, the Rock Island Tributary Committee approved the budget for $149,000.

Evaluating Environmental Impacts of Tumwater Dam

The Committees received a General Salmon Habitat Program proposal from Cascade Columbia Fisheries Enhancement Group titled: *Evaluating Environmental Impacts of Tumwater Dam*. The purpose of the project is to evaluate how Tumwater Dam affects water quality and habitat forming processes. Specifically, the project will (1) quantify the difference between existing and historic habitat conditions within the vicinity of the dam and Lake Jolanda, (2) evaluate how water quality (temperature, dissolved oxygen, etc.) in Lake Jolanda may affect fish migration and behavior, (3) quantify and classify sediments stored behind Tumwater Dam, (4) test sediment behind Tumwater Dam for toxins or heavy metals, and (5) evaluate hydraulics and slope stability of Highway 2 and Lake Jolanda shorelines within a dam removal scenario. The total cost of the project is $279,600. The sponsor requested $139,800 from HCP Plan Species Account Funds. After careful review, the Committees elected to not fund the assessment.

Although the Committees see some value in better understanding entrance efficiency, thermal regimes, and sediments, the Committees believe the cost of the proposed work is too expensive and noted that results from the work will not be compelling enough to lead to dam removal in the near future. Indeed, much of this work would need to be repeated in the future should dam removal ever be considered. Furthermore, the effects of Tumwater Dam on fish have not been identified as important data gaps by the Regional Technical Team, nor is Tumwater Canyon (middle Wenatchee) a priority area for restoration. As noted in the Tributary Committees Funding Policies and Procedures document, an assessment is fundable if the results of the assessment directly and clearly lead to identification, siting, or design of a habitat protection or restoration project or fill a data gap that is identified as a priority in the Upper Columbia Biological Strategy.

VI. Coordination with Bureau of Reclamation on the Sugar Levee Project

Steve Kolk with BOR met with the Committees to discuss a cooperative relationship between the Bureau of Reclamation and the Tributary Committees on the Sugar Levee Project. The purpose of the project is to evaluate removal or breaching of the Sugar Levee, which is located near RM 42.2 in the Middle Reach of the Methow River just upstream from the Town of Twisp. This project will reconnect side channels and more than 17 acres of floodplain habitat. This project was identified as a possible targeted project by the Tributary Committees.

Steve said their Technical Services Center in Denver, CO, is currently using a 2D model to evaluate existing conditions. He said before they begin evaluating possible enhancement alternatives, they need a funding partner. He asked the Tributary Committees if they would be willing to "sign on" with project development. If so, he wants the Tributary Committees engaged in meetings and project development discussions. He also said early involvement in the process will allow all parties to work collaboratively and develop a project with high biological benefit. Although this project is not schedule driven, Steve said they would like to start developing and reviewing alternative designs this summer. BOR is currently in the process of hiring a group to work on designs.

Following Steve's visit with the Tributary Committees, members discussed the risks and benefits of teaming with BOR on this project. Because the relationship allows any party to exit the process at any time, the Committees agreed to work with BOR on developing the Sugar Levee Enhancement Project. Members discussed who from the Committees would participate in the meetings and on conference calls. Kate Terrell, Jeremy Cram, Chris Fisher, and Brandon Rogers agreed to participate in the meetings as time allows. In order to keep all members informed, Tracy Hillman recommended that email communications on the project be shared with everyone on the Committees. In addition, members participating in the process will provide monthly updates to all members on the Committees.

VII. Review of the Yakama Nation Draft SOA

On 25 February, the Yakama Nation submitted a draft Statement of Agreement (SOA) to the Committees for review (see Attachment 2). During the March meeting of the Tributary Committees, Brandon Rogers said the purpose of the draft SOA is to provide a basis for decision making in the HCPs Tributary Committees. He indicated the SOA is draft and asked members to review and discuss it, edit it as necessary, and vote on it during the April meeting. Although members discussed the need (or no need) for an SOA during the March meeting, the Yakama Nation asked members to edit the draft SOA if necessary and be prepared to vote on it during the April meeting.

Tracy Hillman reported that he received no edits to the draft SOA. Therefore, he asked each member to vote on the draft SOA as written and provide their reasons for their yes or no vote. Members voted as follows:

- YN voted yes because there are no written rules for what criteria can and cannot be used to evaluate proposed projects. For example, a member can vote no on a proposed project based on criteria that have nothing to do with the project.
- NMFS voted no because they see no need for an SOA, and it does not address the issue between the tribes (between YN and CCT).
- CCT voted no because they cannot support an SOA that removes their right to prevent the Yakama Nation from owning property in the Upper Columbia.
- USFWS voted no because they see no need for an SOA. They believe the evaluation criteria developed for the Policies and Procedures document provide a sufficient foundation for evaluating project proposals.
- WDFW voted no because the SOA is too restrictive and other factors need to be evaluated in making funding decisions (e.g., competency of the project sponsor to implement the project, cost shares, etc.).
- CPUD voted no because they see no need for the SOA. They support the proposed evaluation criteria in the Policies and Procedures document.
- DPUD voted no because they see no need for the SOA and believe the evaluation criteria being developed are sufficient for evaluating proposed projects. In addition, they do not want members to lose their discretionary voting rights.

Tracy summarized the votes and reasons for the votes and asked the Yakama Nation if they intend to dispute the decision by the Tributary Committees. Brandon said they will discuss this internally and decide what they intend to do. Several members indicated that their organization's vote today will not change in the Coordinating Committee or Policy Committee. Thus, this issue is unlikely to be resolved in any of the HCP Committees. Tracy asked Brandon to let him (Tracy) know if the Yakama Nation needs guidance on initiating the dispute resolution process should they choose to dispute the Tributary Committees decision.

Chris Fisher reminded the group that except for the Scaffold Camp Acquisition #2 Project, the Committees have always made funding decisions based on the cost and biological merits of the proposed project. He said Tracy requires us to provide justification for our decisions. This gives Tracy and Becky the information they need to respond to project sponsor when sponsors question our funding decisions. Chris stated the issue with the Scaffold Project was a policy-level decision for which he had no control. He said policy-level intervention is not likely to change anytime soon.

Tracy thanked everyone for their candid and open discussion on the draft SOA.

VIII. Review of Section 5 of the Policies and Procedures Document

Tracy Hillman said the Committees directed him to add the review criteria discussed during the March meeting to Section 5 of the Committees' Policies and Procedures for Funding Projects. On 21 March 2019, Tracy submitted a draft of Section 5 to the Committees for review. Tracy said he received edits only from Brandon Rogers, which he shared with the Tributary Committees. Brandon's edits included the need for determining if the proposed project was sited within a priority area for restoration or protection. Although members agreed to include the edits, they indicated the need to identify priority areas in the Okanagan subbasin in Canada. The Upper Columbia Regional Technical Team has identified priority areas for restoration and protection only within the U.S. portion of the Upper Columbia. Chris Fisher said he will work with the Okanagan Nation Alliance to identifying priority areas for restoration and protection in Canada.

Following discussion, the Tributary Committees unanimously approved the updated Section 5 of the Policies and Procedures for Funding Projects document (see Attachment 3). They directed Tracy to finalize the Policies and Procedures document. Tracy reminded the Committees they can review and update the evaluation criteria anytime they see necessary.

IX. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from March and April:

   Rock Island Plan Species Account:

   - $112.50 to Clifton Larson Allen for Rock Island financial administration in March 2019.
   - $884.80 to Chelan PUD for Rock Island project coordination and administration during the first quarter of 2019.
   - $247.28 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project.
   - $5,978.75 to Chelan County Treasurer for the Monitor Side Channel Design Project.

   Rocky Reach Plan Species Account:

   - $112.50 to Clifton Larson Allen for Rocky Reach financial administration in March 2019.
   - $863.50 to Chelan PUD for Rocky Reach project coordination and administration during the first quarter of 2019.
   - $183.92 to Cascade Columbia Fisheries Enhancement Group for the Entiat Basin Fish Passage and Screening Assessment Project.

   Wells Plan Species Account:

- $435.11 to Chelan PUD for Wells project coordination and administration during the first quarter of 2019.

2. Tracy Hillman shared the Salmon Recovery Funding Board (SRFB) Schedule with the Committees (see Attachment 4). He said draft proposals are due on 12 April. Project tours are scheduled tentatively for 9 May (Okanogan and Methow), 13 May (Wenatchee), and 14 May (Entiat). Sponsors will give presentations on 12-13 June. The Committees will evaluate the draft proposals on 8 May and decide which projects should be submitted as final proposals. Final proposals are due on 28 June. The Committees will evaluate final proposals and make funding decisions on 11 July.
3. Time permitting, the Tributary Committees will discuss targeted projects during the May meeting.

X. Next Steps

The next scheduled meeting of the Tributary Committees will be on Wednesday, 8 May 2019 at Grant PUD in Wenatchee. The Committees will visit proposed project sites on 9, 13, and 14 May.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Attachment 1
Revised Budget on the Upper Kahler Project

3/29/2019 Cost Proposal to the Rock Island Tributary Committee
Nason Creek - Kahler

Item #	Description	Quantity	Units	Price	Extended Price
001	TESC, SPCC	1	LS	$ 5,000	$ 5,000
002	Mobilization	1	LS	$ 16,000	$ 16,000
003	Road Maintenance	1	LS	$ 5,000	$ 5,000
004	Site Prep, Salvage Trees and Shrubs	1	AC	$ 8,000	$ 8,000
005	Upper Log Structure Site 1	1	LS	$ 30,000	$ 30,000
006	Lower Log Structure Site 1	1	LS	$ 30,000	$ 30,000
007	Log Structure Site 4	1	LS	$ 30,000	$ 30,000
008	Log Structure Site 3	1	LS	$ 25,000	$ 25,000
	Project Total				**$ 149,000.00**

Attachment 2
Draft SOA from the Yakama Nation

Rocky Reach, Rock Island, and Wells HCP Tributary Committees
DRAFT Statement of Agreement

Basis for Decision Making in HCP Tributary Committees
February 25, 2019

Statement

The Rocky Reach, Rock Island, and Wells Habitat Conservation Plans (HCP) Tributary Committees (TCs) agree that mitigation funding decisions will be based exclusively on the merit of proposed projects (biological benefit, technical merit, feasibility, durability, and cost effectiveness) having a direct nexus to plan species, plan species habitat, or plan species management. Signatories agree not to base funding decisions on criteria other than project merit.

Background

The Wells, Rocky Reach, and Rock Island HCP Tributary Committees' Policies and Procedures for Funding Projects (January 10, 2019) describes the eligibility and review criteria for evaluating project funding decisions. Section 5 of that document specifies that project funding decisions are made on the basis of biological benefit, technical merit, feasibility, durability, and cost effectiveness. However, Section 5 does not explicitly disallow criteria unrelated to resource benefits to be introduced into decision-making. The purpose of this SOA is to clarify that the Tributary Committees intend that all funding or other decisions regarding how PUD mitigation is implemented will have a direct nexus to the expected benefits to a plan species or plan species habitat. Decision making by a signatory for reasons unrelated to mitigation benefits are not within the spirit or intent of the HCPs and will impede the operation of the Committees. Any signatory attempting to vote on the basis of criteria other than those directly related to resource impacts may abstain from 'voting'.

Attachment 3
Proposed Section 5 for the Policies and Procedures Document

5 Review Procedures

The Committees will make funding decisions based on eligibility criteria (see Section 4), fund availability, and if necessary, the recommendations from technical advisors. During review of project proposals, the Committees will act in good faith and within the spirit of the collaborative nature of the HCPs to make project funding decisions and having a direct nexus to plan species, plan species habitat, or plan species management. Furthermore, consistent with Section 9 of the HCPs, voting members shall use their best efforts to exercise their rights and authority under statutes, regulations, and treaties, in a manner that allows the goals and objectives of the HCP Agreement to be fulfilled. Importantly, as agreed to during HCP negotiations, funding decisions require unanimous approval of the Committees (as described in HCPs Section 7), affording each member discretionary rights when reviewing and voting on project proposals.

Project proposals will be evaluated based on general and specific criteria. Below we identify the general criteria, which are from the HCPs, and specific criteria, which are based on biological and technical merit, feasibility, durability, and cost-effectiveness. The Committees may also solicit reviews of project proposals from technical experts outside the Committees.

5.1 General Criteria

Project proposals will first be evaluated based on the following general criteria.

Target Species

Does the proposed project address HCP Plan Species (spring Chinook, summer/fall Chinook, coho, sockeye, and/or steelhead)?

Target Area

Is the proposed project located within the geographic scope of the HCPs (projects must be in the Columbia River watershed from Rock Island Dam tailrace to Chief Joseph Dam tailrace)?

5.2 Specific Criteria

Project proposals that address target species within the target area will be evaluated based on biological and technical merit, feasibility, durability, and cost-effectiveness. Separate criteria were established for restoration, protection, design, and assessment projects.

5.2.1 RESTORATION PROJECTS

Biological Benefit

Is the proposed project located within a priority assessment unit or area for restoration?[1]

Is the proposed project sited within an important spawning/rearing area for Plan Species?

Does the proposed project reduce the effects of primary ecological concerns (limiting factors) at the project and reach scale?

Does the proposed project address limiting life stages of Plan Species within the watershed or AU?

Is the proposed project sited within an important spawning/rearing area, or provides access to habitat that would function as important spawning/rearing habitat for Plan Species?

Does the proposed project increase freshwater survival, capacity/abundance, spatial structure, and/or diversity for Plan Species at the project or reach scale?

Technical Merit

Are the methods outlined within the proposal adequate to achieve the stated objectives?

Is the proposed project appropriately scaled and scoped?

Is the proposed project sequenced properly?

Durability

Does the proposed project promote natural stream/watershed processes that are consistent with the geomorphology of the stream?

How long will it take for the proposed project to achieve its intended response?

How long will the proposed project and its benefits persist?

Will the proposed project ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?

Are there permitting or regulatory constraints that will prevent the proposed project from being implemented?

Are there funding constraints that will prevent the project from being implemented?

Does the project sponsor have the experience, resources, and infrastructure to implement the project successfully?

[1] Refer to the UCRTT Biological Strategy for a listing of priority areas for spring Chinook salmon and steelhead. The HCP Hatchery Committees have identified important spawning and rearing areas for summer Chinook. High priority areas for sockeye salmon include spawning habitat in tributaries upstream from Lake Wenatchee and Lake Osoyoos.

Cost Effectiveness

Is the proposed project cost effective (based on the assumed benefit)?

Would other approaches achieve similar or increased biological benefit at lower cost?

Does the proposed project need a cost share? If so, how much?

5.2.2 PROTECTION PROJECTS

Biological Benefit

Is the proposed project located within a priority assessment unit or area for protection? [2]

Is the proposed project sited within an important spawning/rearing area for Plan Species?

To what extent does the proposed project protect high-quality habitat or habitat that can be restored to high quality with appropriate restoration actions?

What would be the anticipated loss in freshwater survival, capacity, spatial structure, and/or diversity of Plan Species at the project or reach scale if the proposed area was developed (i.e., what habitat values would be lost and to what degree would that loss reduce freshwater survival and/or distribution of Plan Species at the project/reach scale)?

Technical Merit

How imminent is the threat of habitat degradation to the proposed land if the project is not implemented?

Will the landowner allow public access?

Will the landowner allow restoration actions?

Durability[3]

Does the proposed project protect watershed processes or important high-quality habitat in perpetuity?

Are there any conditions regarding the protection of the property that could limit the existing high-quality habitat?

Will the proposed project help ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?

Are there funding constraints that will prevent the project from being implemented?

---

[2] Refer to the UCRTT Biological Strategy for a listing of priority areas for spring Chinook salmon and steelhead. The HCP Hatchery Committees have identified important spawning and rearing areas for summer Chinook. High priority areas for sockeye salmon include spawning habitat in tributaries upstream from Lake Wenatchee and Lake Osoyoos.

[3] In Section 7 under Ownership of Assets, the HCPs state that "[a]ll real property purchased shall include permanent deed restrictions to assure protection and conservation of habitat."

Does the project sponsor have the experience, resources, and infrastructure to implement the project successfully?

Cost Effectiveness

Is the proposed project cost effective (based on the assumed benefit)?

Would other approaches achieve similar or increased biological benefit at lower cost?

Does the proposed project need a cost share? If so, how much?

5.2.3 DESIGN PROJECTS

Biological Benefit

Is the proposed project located within a priority assessment unit or area for restoration? [4]

Is the proposed project sited within an important spawning/rearing area for Plan Species?

Will the proposed design lead to development of projects that reduce the effects of primary ecological concerns (limiting factors) at the project and reach scale?

Will the proposed design lead to development of projects that address limiting life stages of Plan Species within the watershed or AU?

Is the proposed design sited within an important spawning/rearing area, or will provide access to habitat that would function as important spawning/rearing habitat for Plan Species?

If the design is implemented, will it increase freshwater survival, capacity/abundance, spatial structure, and/or diversity for Plan Species at the project or reach scale?

Technical Merit

Are the methods outlined within the proposal adequate to achieve the stated objectives?

Is the proposed project appropriately scaled and scoped?

Is the proposed project sequenced properly?

Durability

Will the proposed design lead to development of projects that promote natural stream/watershed processes that are consistent with the geomorphology of the stream?

If the design is implemented, how long will it take for the proposed project to achieve its intended response?

If the design is implemented, how long will the proposed project and its benefits persist?

---

[4] Refer to the UCRTT Biological Strategy for a listing of priority areas for spring Chinook salmon and steelhead. The HCP Hatchery Committees have identified important spawning and rearing areas for summer Chinook. High priority areas for sockeye salmon include spawning habitat in tributaries upstream from Lake Wenatchee and Lake Osoyoos.

If the design is implemented, will the proposed project ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?

Are there permitting or regulatory constraints that will prevent the design from being implemented?

Are there funding constraints that will prevent the design from being implemented?

Does the project sponsor have the experience, resources, and infrastructure to complete the designs?

Cost Effectiveness

Is the proposed project cost effective (based on the assumed benefit)?

Does the proposed project need a cost share? If so, how much?

5.2.4 ASSESSMENT PROJECTS

Biological Benefit

Is the proposed assessment located within a priority assessment unit or area? [5]

Is the proposed assessment sited within an important spawning/rearing area for Plan Species?

Will the proposed assessment lead to projects that reduce the effects of primary ecological concerns (limiting factors) at the project and reach scale?

Will the proposed assessment lead to projects that address limiting life stages of Plan Species within the watershed or AU?

Is the proposed assessment sited within an important spawning/rearing area, or in an area that could function as important spawning/rearing habitat for Plan Species?

Technical Merit

Are the methods outlined within the proposal adequate to achieve the stated objectives?

Is the proposed project appropriately scaled and scoped?

Durability

Will the proposed assessment lead to projects that promote natural stream/watershed processes that are consistent with the geomorphology of the stream?

[5] Refer to the UCRTT Biological Strategy for a listing of priority areas for spring Chinook salmon and steelhead. The HCP Hatchery Committees have identified important spawning and rearing areas for summer Chinook. High priority areas for sockeye salmon include spawning habitat in tributaries upstream from Lake Wenatchee and Lake Osoyoos.

Will the proposed assessment lead to projects that ameliorate the effects of climate change?

Feasibility

Is there a signed landowner agreement form?

Are there permitting or regulatory constraints that will prevent the assessment from being implemented?

Are there funding constraints that will prevent the assessment from being implemented?

Does the project sponsor have the experience, resources, and infrastructure to complete the assessment?

Cost Effectiveness

Is the proposed project cost effective (based on the assumed benefit)?

Does the proposed project need a cost share? If so, how much?

All decisions on funding will be held in a closed executive session. The Committees reserve the right to hold closed sessions on other issues, when necessary. Project proposal presentations may be open to the public. All other meetings will be open by invitation only. The Committees may use the Mid-Columbia Forum[6] to inform stakeholders of the status of the Plan Species Account(s). Decisions by the Committees are final and not subject to review by any entity.

The Committees may sponsor workshops for all stakeholders to present the annual Plan activities and project selection policies and procedures. Successful project applicants may be asked to present the status of their projects during these workshops.

[6] The Mid-Columbia Forum is a meeting of the HCP Coordinating, Hatchery, and Tributary Committees with stakeholders, including the Confederated Tribes of the Umatilla Indian Reservation and American Rivers, who were involved in negotiating the HCPs but elected to not sign the HCPs. The purpose of the meeting is to provide stakeholders with a progress report on implementation, as well as give them an opportunity to ask questions of the Committee members.

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 8 May 2019

Members Present: Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Tom Kahler (Douglas PUD), Brandon Rogers (Yakama Nation), Kate Terrell (USFWS), Catherine Willard (Chelan PUD), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Others Present: Becky Gallaher (Tributary Project Coordinator).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Wednesday, 8 May 2019 from 9:00 am to 12:00 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda.

II. Review and Approval of Meeting Minutes

Tributary Committees members reviewed and approved the 11 April 2019 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- Barkley Irrigation – Under Pressure Project – The sponsor (Trout Unlimited; TU) reported they continue to make progress on the MVID inlet and Phase 1 piping. Phase 1 piping should be completed by early June.
- Icicle Boulder Field Project – The sponsor (TU) reported they continue to work through the permitting process. Department of Ecology has requested the sponsor develop a boulder breaking plan and a Temporary Erosion and Sediment Control Plan. They will also be developing a Stormwater Pollution Prevention Plan as part of the NPDES permit. Public comment period closed on the SEPA and county shorelines. There were no notable comments.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – This project is complete. The sponsor (WDFW) will provide the next annual report on 31 December 2019.
- Burns-Garrity Design Project – This project is complete. The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) provided a final report, which was uploaded to the Extranet site.
- Beaver Fever Project – The sponsor (TU) indicated they have been coordinating with USFS on BDA installations in Potato and Roaring creeks. The sponsor is also working with USFS on the permitting pathway.

- Methow Basin Barrier Diversion Assessment Project – The sponsor (CCFEG) did not provide an update this month.
- Derby Creek Fish Passage Project – The sponsor (CCFEG) reported NRCS has completed the hydraulic review and the sponsor can now order the box culvert. They are currently evaluating whether to construct this year or next. Before bidding the project, the sponsor needs a construction estimate and final designs and construction documents from WDFW engineering.
- Chiwawa Nutrient Enhancement Project – The sponsor (CCFEG) reported no new activity this month.
- Monitor Side Channel Design Project – The sponsor (Chelan County Natural Resources Department; CCNRD) reported they and Natural Systems Design refined restoration plans and produce a preliminary site map and construction cost estimates. These were included in the draft SRFB/TC application.
- Peshastin Creek Environmental Site Assessment Project – The sponsor (CCNRD) reported that Phase 1 fieldwork will be completed on 10 May 2019.
- Entiat Fish Passage and Barrier Assessment Project – The sponsor (CCFEG) reported there was no new activity this month.
- Twisp River Floodplain Left Bank Spring-fed Alcove Restoration Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported they are working on SEPA and JARPA.
- Johnson Creek Habitat Restoration Project – The sponsor (TU) did not provide an update this month.
- Cottonwood Flats Floodplain Restoration Project – The sponsor (CCNRD) reported that construction will begin fall 2020.

IV. General Salmon Habitat Program Draft Applications

The Committees received 18 General Salmon Habitat Program draft proposals. The Committees reviewed each draft proposal and selected those they believe warranted a final proposal.[1] Projects the Committees dismissed were either inconsistent with the intent of the Tributary Fund, did not have strong technical merit, or had low benefits per cost (not cost effective). The Committees assigned draft proposals to one of two categories: Fundable (would like to see a final application) and Not Fundable (would not like to see a final application). It is important to note that these are ratings of draft proposals and do not reflect ratings of final proposals. The Committees directed Tracy Hillman to notify sponsors with appropriate projects to submit a final proposal, with a discussion of the questions/comments identified for each draft proposal listed below. Tracy will also notify sponsors with projects that have no chance or a low likelihood of receiving funding from the Tributary Committees.

Nason and Kahler Creek Confluence Acquisition Project (Fundable)

The Committees recommend that the project sponsor (Chelan Douglas Land Trust) submit a full proposal. The Committees had no comments on this project.

Restore Lower Chiwaukum Creek – Phase 1 (Fundable)

The Committees recommend that the project sponsor (Cascade Columbia Fisheries Enhancement Group) address the following comments/suggestions as they develop the full proposal:

[1] The Committees held a conference call on Tuesday, 21 May 2019 to discuss observations from the site visits and reassess their designation of proposed projects as fundable (would like to see a final application) or not fundable (do not want to see a final application).

- Identify any constraints the Forest Service may have on this project before identifying enhancement alternatives.
- Evaluation of alternatives needs to consider post-fire effects (e.g., changes in hydrology, debris flows, temperature effects, etc.).
- The evaluation of alternatives needs to consider the removal of camping sites located within the riparian area.

Monitor Side Channel Construction Project (Fundable)

The Committees recommend that the project sponsor (Chelan County Natural Resources Department) submit a full proposal. The Committees had no comments on this project.

Upper Wenatchee Side Channel RM 38.9-40.2 Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- The Yakama Nation will be implementing enhancement actions at this site. Thus, there is no need for another project at this site.

Peshastin RM 4.3 Side Channel Project (Fundable)

The Committees recommend that the project sponsor (Chelan County Natural Resources Department) address the following comments/suggestions as they develop the full proposal:

- Need to update the project schedule within the application.
- Include a signed landowner willingness form with the final application.
- Use the segments of Peshastin Creek upstream and just downstream from the proposed project site as a reference for designing the floodplain and side channel reconnections.

Icicle and Peshastin Irrigation Districts Full Season Pumping Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- The Committees believe there are too many unknowns regarding the implementation of this project. Some of those include:
    - The precise location of the proposed micro-hydropower facility is unclear.
    - It is unknown how power generated at the micro-hydropower facility will enter the power grid and what infrastructure is required to make that happen.
    - There are uncertainties regarding Snow Creek water rights.
    - It is unclear if there is or has been coordination with the Leavenworth Fish Hatchery.
    - O&M costs are mostly unknown and there is no cost estimate for the construction of a micro-hydropower facility.
    - There are no results from the original pump-station design.

The Committees are interested in better understanding this project and would like to schedule a meeting with Tony Jantzer to discuss the project in more detail.

Nason Ridge Acquisition Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- The Committees are not interested in funding an acquisition that includes mostly uplands. However, the Committees would review a proposal seeking funds to acquire the floodplain and riparian habitat along Nason Creek if the floodplain can be separated from the uplands.

Wenatchee EDT Model Development Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- The Committees understand that the Upper Columbia Regional Technical Team is developing a prioritization tool for the Wenatchee sub-basin. They also understand that this tool, which is intended to update the Upper Columbia Biological Strategy, has not been fully developed and tested at this time. If it is determined that the prioritization tool works, there may be no need for a second prioritization tool.
- Given that EDT has produced some questionable results in the Methow sub-basin, the Committees want to see how well the model performs in the Methow once additional habitat data are collected to help populate the model, before proceeding with EDT implementation in the Wenatchee.

Eagle Creek Fish Passage Barrier Removal – RM 0.3 Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- Although the barrier prioritization tool identified the lower Eagle Creek culvert as a priority barrier, the tool also evaluates clusters of barriers within a stream or small watershed. In this case, it is not appropriate to evaluate the lower barrier (which is a partial barrier) in isolation from the other roughly 20 barriers in Eagle Creek. When evaluating the cluster of barriers within the stream, it does not appear the biological benefit justifies the cost of replacing all barriers at the per-barrier cost in the proposal. That is, barrier replacement in Eagle Creek does not appear to be cost effective.
- Eagle Creek is not considered a high priority area for restoration.

Lower Wenatchee Instream Flow Enhancement Phase II Project (Fundable)

The Committees recommend that the project sponsor (Trout Unlimited) address the following comments/suggestions as they develop the full proposal:

- Identify the level of certainty that the sponsor will receive the $2M cost share.
- Provide specific information on the quality of water discharged back into the Wenatchee River. If available, provide the concentrations of pollutants and the temperature of the return water.
- Indicate the average amount of irrigation water returned to the Wenatchee River under current conditions. Also, indicate the amount of flow within the Wenatchee River at the times when water is diverted.

<u>Burns-Garrity Side Channel Project (Not Fundable)</u>

The Committees recommend that this project, sponsored by Cascade Columbia Fisheries Enhancement Group, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- The Committees believe the groundwater yield is too low to support Plan Species.
- The Committees would like to better understand the evolution of the main channel given the recent avulsion. They are not convinced the side channel will function appropriately for Plan Species over the long term given the dynamic nature of the main channel at this location.

<u>Restoration Strategy for the Upper Methow Project (Not Fundable)</u>

The Committees recommend that this project, sponsored by Cascade Columbia Fisheries Enhancement Group, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- The Committees believe the Upper Methow Reach Assessment provides adequate information to guide enhancement projects in this reach of the upper Methow River. They see no need for additional assessments in this reach.
- A better approach is to submit an application for design work, which includes enough budget to assess alternatives.

<u>Okanogan Basin Barrier Assessment Project (Not Fundable)</u>

The Committees recommend that this project, sponsored by Cascade Columbia Fisheries Enhancement Group, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- The Committees believe barriers within the anadromous zone within the Okanogan sub-basin are mostly known and have been or are being addressed.
- The Committees also understand that barriers upstream from natural barriers are clustered and the biological benefit gained from addressing clusters of barriers outside the anadromous zone will not justify the cost.

<u>Fuller Side Channel Well Conversion Project (Not Fundable)</u>

The Committees recommend that this project, sponsored by the Methow Salmon Recovery Foundation, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- This project will have little to no biological benefit.
- The Committees also believe this project is too expensive. The total cost of the project should be under $100,000.

<u>Upper Burns and Angle Point Areas Habitat Enhancement Project (Fundable)</u>

The Committees recommend that the project sponsor (Yakama Nation) address the following comments/suggestions as they develop the full proposal:

- Provide maps, pictures, preliminary design drawings, and modeling results supporting design in the final proposal.
- Indicate whether the landowner supports this project.
- Consider a seasonal side channel. Not all side channels need to be perennial and this may be a good location for a seasonal channel.
- Consider adjustments to the opening of the side channel and let the river carve the side channel.
- The application refers to enhancement work that began in 2017 adjacent to the proposed project

area. If available, provide any data or information on the use of these enhancement structures by Plan Species (i.e., Chinook, steelhead, and/or coho).

- Consider a construction method that minimizes disturbance of existing riparian vegetation, such as excavating a trench to design elevation and allowing the river to contour the channel banks, rather than grading side slopes to form a trapezoidal channel. If the design team determines that such an approach is not acceptable, please provide and justify the rationale for that decision.

Nason Confluence Habitat Enhancement Project (Not Fundable)

The Committees recommend that this project, sponsored by the Yakama Nation, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- Because of the sediment dynamics and high sediment load within Nason Creek, the Committees believe maintaining a side channel at the mouth of Nason Creek will be difficult. Thus, they question the longevity of the project.
- The Committees are concerned regarding the amount of established riparian vegetation that would be removed or destroyed during project implementation.
- The application would benefit from having maps, pictures, and preliminary design drawings.

Golden Doe Large Wood Project (Fundable)

The Committees recommend that the project sponsor (Yakama Nation) address the following comments/suggestions as they develop the full proposal:

- Provide maps, pictures, and preliminary design drawings in the final proposal.
- Because this is a dynamic area, consider using large-wood apex jams at the upstream end of the project area (to direct flows into specific channels) and drive pilings downstream from the apex jams to catch wood to improve peripheral and transitional habitat.
- The Committees are concerned that the side channel will not be maintained because of the sediment dynamics at this site. The sponsor needs to describe how the side channel will be maintained over time.
- Indicate if the proposed project intends to use groundwater to maintain flows in the side channel. If so, will intercepting groundwater affect riparian vegetation along the channel?

Napeequa Side Channel Connection Project

Although it was not clear in the application if the project sponsor (Cascade Columbia Fisheries Enhancement Group) was seeking funding from the Habitat Conservation Plans Tributary Committees, the Committees nevertheless reviewed the application. The purpose of the project is to remove a culvert and associated fill to restore hydraulic connectivity to a side channel along the lower Napeequa River, a tributary to the White River. This action will improve juvenile steelhead and spring Chinook survival and productivity by providing access to an important spring-fed side channel. The total cost of the project is $58,290.00. After careful review of the proposal, the ***Rocky Reach Tributary Committee elected to contribute $49,399.00 to the project*** (the project has a cost share of $8,891.00). The Committee recommended the sponsor consider a less expensive pedestrian bridge over the Napeequa River.

V. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from April and May:

   Rock Island Plan Species Account:

- $865.51 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project.
- $461.69 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project.
- $8,996.08 to Chelan County Treasurer for the Monitor Side Channel Design Project.

Rocky Reach Plan Species Account:

- $141.07 to Cascade Columbia Fisheries Enhancement Group for the Burns-Garrity Restoration Design Project.
- $690.90 to Cascade Columbia Fisheries Enhancement Group for the Entiat Basin Fish Passage and Screening Assessment Project.

2. Tracy Hillman shared the Salmon Recovery Funding Board (SRFB) Schedule with the Committees (see Attachment 1). He said project tours are scheduled for 9 May (Methow), 13 May (Wenatchee), and 14 May (Entiat). Sponsors will give presentations on 12-13 June. Final proposals are due on 28 June. The Committees will evaluate final proposals and make funding decisions on 16 July.
3. Tracy Hillman reported that he informed Steve Kolk (Bureau of Reclamation; BOR) that the Tributary Committees are interested in partnering with BOR on the Sugar Levee Project. BOR will coordinate with the Committees on future meetings and field trips. BOR should have 2D model results available for Committees' review by the end of April.

VI. Next Steps

The next scheduled meeting of the Tributary Committees will be on Tuesday, 16 July at Grant PUD in Wenatchee. The Committees will visit proposed project sites on 9, 13, and 14 May and attend presentations on 12-13 June.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 16 July 2019

Members Present: Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Tom Kahler (Douglas PUD), Brandon Rogers (Yakama Nation), Kate Terrell (USFWS), Catherine Willard (Chelan PUD), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Others Present: Becky Gallaher (Tributary Project Coordinator).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Wednesday, 16 July 2019 from 9:00 am to 12:40 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda.

II. Review and Approval of Meeting Minutes

Tributary Committees members reviewed and approved the 8 May 2019 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- Barkley Irrigation – Under Pressure Project – The sponsor (Trout Unlimited; TU) reported they completed Phase 1 piping on 10 June. This allowed Barkley/MVID to start running irrigation to their shareholders. The easements with the DOT/FAA and adjacent property owners along the Barkley and MVID pipe aliment continue to move slowly.
- Icicle Boulder Field Project – The sponsor (TU) reported they are waiting on federal permits and are planning on a late summer/early fall bid walk. They also continue to work closely with WDFW and are also working through the funding process for the City of Leavenworth fish screen.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – This project is complete. The sponsor (Washington Department of Fish and Wildlife; WDFW) will provide the next annual report on 31 December 2019.
- Beaver Fever Project – The sponsor (TU) reported they continue to wait on the USFS internal processes for moving forward with Roaring Creek and Potato Creek BDA installation in 2019 or 2020.
- Methow Basin Barrier Diversion Assessment Project – The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) did not provide an update this month.

- Derby Creek Fish Passage Project – The sponsor (CCFEG) reported that because of a delay in final design development, it will be too late to have the concrete box culvert manufactured this year. Therefore, they requested a time extension to 15 December 2020 (see discussion below).
- Chiwawa Nutrient Enhancement Project – The sponsor (CCFEG) reported they are preparing for the field season.
- Monitor Side Channel Design Project – The sponsor (Chelan County Natural Resources Department; CCNRD) reported they conducted a site tour with WDFW and WDOT to secure early feedback on project plan and preliminary designs.
- Peshastin Creek Environmental Site Assessment Project – The sponsor (CCNRD) reported that their consultant is working on the draft report.
- Entiat Fish Passage and Barrier Assessment Project – The sponsor (CCFEG) reported they are preparing for the field season.
- Twisp River Floodplain Left Bank Spring-fed Alcove Restoration Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported permits have been secured with WDFW and Okanogan County. They expect permits from the Corps of Engineers and Ecology soon. They currently have a landowner agreement with one of the three landowners. Construction is scheduled to start 12 July.
- Johnson Creek Habitat Restoration Project – The sponsor (TU) did not provide an update this month.
- Cottonwood Flats Floodplain Restoration Project – The sponsor (CCNRD) reported construction will occur during fall 2020.
- Upper Kahler Stream and Floodplain Project – The Tributary Committee/Sponsor Agreement has been executed.
- Stormy Area "A: Stream and Floodplain Enhancement Project – The Tributary Committee/Sponsor Agreement has been executed.
- Napeequa Side Channel Connection Project – The Tributary Committee/Sponsor Agreement is ready for signature.

IV. Budget Amendment Request

Lower Derby Creek Fish Passage Project

In June, the Rock Island Tributary Committee received a budget amendment request from Cascade Columbia Fisheries Enhancement Group on the Lower Derby Creek Fish Passage Project. Because of unforeseen changes in the project, the sponsor requested an additional $32,196 from the Committee. The Committee originally approved $65,000 for the project. With the budget amendment, the total request from the Rock Island Tributary Committee will be $97,196. In June, the Rock Island Tributary Committee approved the budget amendment.

V. Time Extension Request

Lower Derby Creek Fish Passage Project

In July, the Rock Island Tributary Committee received a time extension request from Cascade Columbia Fisheries Enhancement Group on the Lower Derby Creek Fish Passage Project. Because of a delay in completing final designs, the sponsor requested a time extension from 1 December 2019 to 1 December 2020. After careful consideration, the Rock Island Tributary Committee approved the time extension.

VI. General Salmon Habitat Program Draft Applications

The Committees received 12 General Salmon Habitat Program proposals that were cost shares with the Salmon Recovery Funding Board (SRFB). In addition, they received an application from WDFW that was not a cost share with the SRFB.

Before reviewing the proposals and consistent with the Committees' Operating Procedures, members of the Committees identified potential conflicts of interest. Brandon Rogers recused himself from discussing and voting on the two Yakama Nation proposals.

Becky Gallaher provided the Committees with the unallocated balances within each Plan Species Account. The Wells Account has $1,813,698, the Rocky Reach Account has $2,270,634, and the Rock Island Account has $6,389,534. In sum, among the three accounts, there is $10,473,866 available to fund projects.

Nason and Kahler Creek Confluence Acquisition Project

Chelan-Douglas Land Trust is the sponsor of the Nason and Kahler Creek Confluence Acquisition Project. The purpose of this project is to purchase and protect 80 acres of riparian/floodplain habitat along lower Kahler Creek, a tributary to Nason Creek. The total cost of the acquisition was $369,150. The sponsor requested $231,500 from HCP Plan Species Account Funds. Although the Committees found the project worthy of funding, they withdrew the application because the Priest Rapids Coordinating Committee Habitat Subcommittee elected to fund this project.

Restore Lower Chiwaukum Creek – Phase I Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the Restore Lower Chiwaukum Creek – Phase I Project. The purpose of the project is to evaluate the geomorphology and fish habitat within the lower one mile of Chiwaukum Creek, and create effective enhancement designs. Chiwaukum Creek is a tributary to the Wenatchee River. The total cost of the project was $116,256. The sponsor requested $55,098 from HCP Plan Species Account Funds. The ***Rock Island Tributary Committee elected to contribute $55,098 to the project***. As part of funding for this project, the Committee requires that they review and approve restoration scenarios and designs.

Monitor Side Channel Construction Project

Chelan County Natural Resources Department is the sponsor of the Monitor Side Channel Construction Project. The purpose of the project is to construct large wood structures and boulder clusters within the Monitor Side Channel and enhance riparian habitat along the side channel, which is located within the lower Wenatchee River. The total cost of the project was $296,530. The sponsor requested $148,265 from HCP Plan Species Account Funds. The ***Rock Island Tributary Committee elected to contribute $148,265 to the project***.

Peshastin RM 4.3 Side Channel Project

Chelan County Natural Resources Department is the sponsor of the Peshastin RM 4.3 Side Channel Project. The purpose of the project is to design a 1,200-foot long side channel along Peshastin Creek, a tributary to the Wenatchee River. The total cost of the project was $99,010. The sponsor requested $19,802 from HCP Plan Species Account Funds. The ***Rock Island Tributary Committee elected to contribute $19,802 to the project***.

IPID Full Season Pumping Project

Chelan County Natural Resources Department is the sponsor of the IPID Full Season Pumping Project. The purpose of the project is to design a full-season, pressurized, pumpback system for the Icicle and Peshastin Irrigation Districts. This system will allow for the decommissioning of the Peshastin Irrigation

Diversion. The total cost of the project was $135,000. The sponsor requested $67,500 from HCP Plan Species Account Funds. The Committees declined the opportunity to fund this project.

The Committees understand there is about $120,000 remaining in the Peshastin Irrigation District Pump Exchange Preliminary Design Project. Because of landowner issues associated with that project, and the clear overlap in project scope with the proposed project, the Committees recommend that the sponsor work with the Salmon Recovery Funding Board on changing the scope of the Peshastin Irrigation District Pump Exchange Preliminary Design Project and amend its budget to include the proposed work. The Committees would review a revised proposal if the resulting budget amendment is inadequate to complete the Peshastin Irrigation District Full-Season Pumpback Project.

Nason Ridge Acquisition Project

Chelan County Natural Resources Department is the sponsor of the Nason Ridge Acquisition Project. The purpose of the project is to protect 3,714 acres of riparian, floodplain, and upland habitat within the Nason Creek watershed. In sum, the acquisition will protect 506 acres of riparian and floodplain habitat along lower Nason Creek. The acquisition will also allow upland restoration actions that will reduce fine sediment recruitment to Nason Creek. The total cost of the project was $5,500,000. The sponsor requested $500,000 from HCP Plan Species Account Funds. The ***Rock Island Tributary Committee elected to contribute $500,000 to the project***. This funding is contingent on the Committee’s review and approval of the draft management plan. At a minimum, it is important to the Committee that the road density be reduced to at least 2 miles per square mile. This will directly benefit Plan Species within the project area.

Wenatchee EDT Model Development Project

Chelan County Natural Resources Department is the sponsor of the Wenatchee EDT Model Development Project. The purpose of the project is to build a model-based synthesis platform for monitoring data to support habitat status and trends reporting and restoration planning. The tool will help identify and prioritize enhancement actions, develop conceptual designs, and evaluate biological benefits and feasibility. The total cost of the project was $318,000. The sponsor requested $48,000 from HCP Plan Species Account Funds. The Committees declined the opportunity to fund this project.

The Committees understand that the Upper Columbia Regional Technical Team is developing a prioritization tool for the Wenatchee sub-basin. The Committees also understand that this tool, which is intended to update the Upper Columbia Biological Strategy, has not been fully developed and tested at this time. If it is determined the prioritization tool works, there may be no need for a second prioritization tool, such as EDT. In addition, given that EDT has produced some questionable results in the Methow sub-basin, the Committees want to see how well the model performs in the Methow once additional habitat data are collected to help populate the model, before proceeding with EDT implementation in the Wenatchee sub-basin. This was the expressed opinion of the Committees regarding the 2018 application, and given the remaining uncertainty around the suitability of the Methow EDT, the Committees’ decision is unchanged.

Lower Wenatchee Instream Flow Enhancement Phase II Project

Trout Unlimited is the sponsor of the Lower Wenatchee Instream Flow Enhancement Phase II Project. The purpose of the project is to conserve up to 15 cfs of water in the lower Wenatchee River by developing a pressurized irrigation system. The system will also eliminate the return of warm irrigation water that is contaminated with agricultural chemicals. The total cost of the project was $2,500,000. The sponsor requested $250,000 from HCP Plan Species Account Funds. The ***Rock Island Tributary Committee elected to contribute $250,000 to the project***.

Upper Burns and Angle Point Areas Habitat Enhancement Project

The Yakama Nation is the sponsor of the Upper Burns and Angle Point Areas Habitat Enhancement Project. The purpose of the project is to reconnect relic side channels and install large wood structures within the mainstem Entiat River. The total cost of the project was $1,070,500. The sponsor requested $189,000 from HCP Plan Species Account Funds. The ***Rock Island Tributary Committee elected to contribute $189,000 to the project***.

Golden Doe Large Wood Project

The Yakama Nation is the sponsor of the Golden Doe Large Wood Project. The purpose of the project is to recreate large, bar-apex wood structures in a wide anabranching segment of the Methow River between Twisp and Carlton. The total cost of the project was $1,004,590. The sponsor requested $200,270 from HCP Plan Species Account Funds. The Committees declined the opportunity to fund this project.

The Committees believe the proposed enhancement site is located in a very dynamic reach, which means there is considerable uncertainty as to how the river will respond to the proposed structures and whether the structures will provide habitat for HCP Plan Species for a long enough period of time to warrant the substantial investment. Given these uncertainties, the Committees believe a lighter, less expensive approach, which includes the use of a few apex jams and pilings, would be best suited for this site.

Upper Methow Restoration Assessment and Design Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the Upper Methow Restoration Assessment and Design Project. The purpose of the project is to develop restoration designs and a protection strategy for the Upper Methow River. The sponsor will compile available data, identify and fill data gaps, initiate stakeholder outreach, and develop enhancement concepts and a protection strategy. The total cost of the project was $80,200. The sponsor requested $35,500 from HCP Plan Species Account Funds. The Committees declined the opportunity to fund this project because they are not interested in funding additional assessment work. However, they would review applications for preliminary and final enhancement designs.

Okanogan Basin Barrier Assessment Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the Okanogan Basin Barrier Assessment Project. The purpose of the project is to conduct a comprehensive fish passage barrier assessment throughout the Okanogan River sub-basin, including areas upstream from anadromy. The total cost of the project was $193,826. The sponsor requested $22,000 from HCP Plan Species Account Funds. The Committees declined the opportunity to fund this project because they believe barriers within the anadromous zone are already known. In addition, they see relatively little value in assessing barriers outside the anadromous zone because there is a low likelihood those barriers will be addressed anytime soon. Finally, barriers above the anadromous zone are also outside the zone for Plan Species, and thus ineligible for Tributary Committees funding.

2019 Eightmile Creek Fisheries Assessment Project

Washington Department of Fish and Wildlife is the sponsor of the 2019 Eightmile Creek Fisheries Assessment Project. This project did not have a SRFB cost share. The purpose of the project is to identify fish abundance, stream flows, and water temperatures to guide permitting and selecting a brook trout removal strategy for Eightmile Creek, a tributary to the Chewuch River. The total cost of the project was $130,183. The sponsor requested $125,183 from HCP Plan Species Account Funds. The Committees were unable to make a funding decision at this time. This is primarily because the fish passage barrier is scheduled to be removed in 2020 and therefore there is no need for an assessment or development of a brook trout management plan. The Committees believe the sponsor should focus on removing as many brook trout as they can before passage is provided. As such, the Committees recommended the following:

- Propose a multiple-pass electrofishing effort to remove as many brook trout as possible before they spawn this fall. An additional removal effort could also occur next summer before barrier removal. Under this approach, there is no need for block nets because the entire length of stream is fished on more than one occasion within a short period of time (see Thompson and Rahel (1996) and Buktenica et al. (2013), which were provided to the sponsor earlier).
- Remove genetic sampling as there is no need for it given that passage will be provided and, because a rotenone treatment is not necessary (given electrofishing removal efforts), there is also no need to identify or quantify bull trout losses that would occur with piscicide application. The Committees appreciate the desire to better understand the genetics of bull trout and brook trout; however, neither are Plan Species, and as a result, Plan Species Account Funds cannot be used to fund this effort.
- Please remove any costs associated with renting electrofishing gear. The Committees understand that WDFW has electrofishing gear available for the work and the Colville Confederated Tribes (CCT) have indicated they are willing to let the sponsor use their electrofishing gear if necessary.
- The Committees recommend that you discuss this project with both Jeremy Cram (WDFW) and Chris Fisher (CCT). Chris Fisher indicated that he may be able to provide technicians and gear if necessary.

Summary of Review of 2019 General Salmon Habitat Program Projects

Project Name	Sponsor[1]	Total Cost	Request from T.C.	T.C. Contribution[2]
Nason and Kahler Creek Confluence Acquisition	CDLT	$369,150	$184,575	$0
Restore Lower Chiwaukum Creek – Phase 1	CCFEG	$116,256	$55,098	RI: $55,098
Monitor Side Channel Construction	CCNRD	$296,530	$148,265	RI: $148,265
Peshastin RM 4.3 Side Channel	CCNRD	$99,010	$19,802	RI: $19,802
IPID Full Season Pumping Project	CCNRD	$135,000	$67,500	$0
Nason Ridge Acquisition	CCNRD	$5,500,000	$500,000	RI: $500,000
Wenatchee EDT Model Development	CCNRD	$318,000	$48,000	$0
Lower Wenatchee Instream Flow Enhancement	TU	$2,500,000	$250,000	RI: $250,000
Upper Burns & Angle Point Areas Enhancement	YN	$1,070,500	$189,000	RI: $189,000
Golden Doe Large Wood Project	YN	$1,004,590	$200,270	$0
Upper Methow Restoration Assessment and Design	CCFEG	$80,200	$35,500	$0
Okanogan Basin Barrier Assessment	CCFEG	$193,826	$22,000	$0
2019 Eightmile Creek Fisheries Assessment	WDFW	$130,183	$125,183	No decision
Total:		**$11,813,245**	**$1,845,193**	**$1,162,165**

[1] CCFEG = Cascade Columbia Fisheries Enhancement Group; CCNRD = Chelan County Natural Resources Department, CDLT = Chelan-Douglas Land Trust, TU = Trout Unlimited, WDFW = Washington Department of Fish and Wildlife, and YN = Yakama Nation.

[2] RI = Rock Island Plan Species Account; RR = Rocky Reach Plan Species Account; W = Wells Plan Species Account.

VII. HCP Policy Committees Guidance

Tracy Hillman shared with the HCP Tributary Committees the guidance that was provided by the HCP Policy Committees. Specific to the HCP Tributary Committees:

- The Tribal Councils of the Yakama Nation and Colville Confederated Tribes will meet to discuss a third-party owner (e.g., WDFW) for the Scaffold Camp #2 Acquisition Project in the Twisp River watershed. Brandon Rogers reported that the Yakama Nation already purchased the property. Therefore, there is no need for the Policy Committees to address the Scaffold Camp #2 Acquisition Project.
- The Tribal Councils will also provide guidance on landownership. PUD staff and other signatories will likely be asked to describe the meaning and intent of the HCPs to the Councils.
- The Tributary Committees will evaluate all project applications based on biological and technical merits, feasibility, durability, and cost-effectiveness. All policy-level issues will be evaluated by the HCP Policy Committees. In addition, technical members can abstain from voting on a decision item that has policy-level implications.

VIII. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from May, June, and July:

   Rock Island Plan Species Account:

   - $127.50 to Clifton Larson Allen for Rock Island financial administration in April and May 2019.
   - $75.00 to Clifton Larson Allen for Rock Island financial administration in June 2019.
   - $602.48 to Chelan PUD for Rock Island project coordination and administration during the second quarter of 2019.
   - $259.61 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project for work in May.
   - $1,509.66 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project for work in June.
   - $395.16 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project for work in May.
   - $680.03 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project for work in June.
   - $1,195.56 to Chelan County Treasurer for the Monitor Side Channel Design Project for work in May.
   - $3,701.08 to Chelan County Treasurer for the Monitor Side Channel Design Project for work in June.
   - $808.13 to Trout Unlimited for the Beaver Fever: Restoring Ecosystem Function Project.
   - $15,492.41 to Trout Unlimited for the MVID Instream Flow Improvement Project.

   Rocky Reach Plan Species Account:

- $127.50 to Clifton Larson Allen for Rocky Reach financial administration in April and May 2019.
- $75.00 to Clifton Larson Allen for Rocky Reach financial administration in June 2019.
- $571.23 to Chelan PUD for Rocky Reach project coordination and administration during the second quarter of 2019.
- $200.20 to Chelan County Treasurer for the Peshastin Creek RM 8.8 Channel Reconnection – Site Assessment Project for work in May.
- $2,577.50 to Chelan County Treasurer for the Peshastin Creek RM 8.8 Channel Reconnection – Site Assessment Project for work in June.
- $1,220.68 to Cascade Columbia Fisheries Enhancement Group for the Entiat Basin Fish Passage and Screening Assessment Project for work in May.
- $1,380.50 to Cascade Columbia Fisheries Enhancement Group for the Entiat Basin Fish Passage and Screening Assessment Project for work in June.

Wells Species Account:

- $319.06 to Chelan PUD for Wells project coordination and administration during the second quarter of 2019.

2. Tracy Hillman reported that he received a request from the Upper Columbia Salmon Recovery Board asking if the Tributary Committees would be interested in helping sponsor the 2020 Science Conference, which will be on 23-24 January 2020 in Wenatchee. The Wells, Rocky Reach, and Rock Island Tributary Committees each agreed to donate $1,000.00 to the Conference. Funding will come from administrative expenses (not to exceed $80,000 per year per account) under the Plan Species Accounts. This level of sponsorship identifies each of the Committees as a "Gold Sponsor."
3. Tracy Hillman reminded the Committees that there will be a Peshastin Pumpback Project meeting on 23 July from 10:00 am to noon at the IPID office at 5594 Wescott Dr. in Cashmere. Members are encouraged to attend this meeting.

IX. Next Steps

The next scheduled meeting of the Tributary Committees will be on Thursday, 8 August at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 8 August 2019

Members Present: Chris Fisher (Colville Tribes), Tom Kahler (Douglas PUD), Brandon Rogers (Yakama Nation), Kate Terrell (USFWS), Catherine Willard (Chelan PUD), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Members Absent: Jeremy Cram (WDFW)

Others Present: Becky Gallaher (Tributary Project Coordinator), Allison Lutes (Chelan County Natural Resources Department), Nic Truscott (Natural Systems Design), Kari Alex (Okanagan Nation Alliance), Dave Duvall (Grant PUD), and Steve Kolk (Bureau of Reclamation).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Wednesday, 8 August 2019 from 9:00 am to 12:45 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with the removal of the Napeequa Side Channel budget amendment. The project sponsor (Cascade Columbia Fisheries Enhancement Group) pulled the budget amendment request.

II. Review and Approval of Meeting Minutes

Tributary Committees members reviewed and approved the 16 July 2019 meeting notes with edits.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- Barkley Irrigation – Under Pressure Project – The sponsor (Trout Unlimited; TU) reported the bid package for Phase II piping is in review and should be out for solicitation the third week of August. Work has begun on the Boesel well. The plan is to have all five wells drilled by the end of the month.
- Icicle Boulder Field Project – The sponsor (TU) reported they are working on the bid package for solicitation in mid-August. They continue to work through the permitting process.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – This project is complete. The sponsor (Washington Department of Fish and Wildlife; WDFW) will provide the next annual report on 31 December 2019.

- Beaver Fever Project – The sponsor (TU) reported that the Forest Service is still evaluating proposed projects. The sponsor is hopeful they will receive approval soon.
- Methow Basin Barrier Diversion Assessment Project – The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) did not provide an update this month.
- Derby Creek Fish Passage Project – The sponsor (CCFEG) held a design team meeting to discuss what work still needs to be completed before going to bid in 2020.
- Chiwawa Nutrient Enhancement Project – The sponsor (CCFEG) reported they are preparing for the field season.
- Monitor Side Channel Design Project – The sponsor (Chelan County Natural Resources Department; CCNRD) reported that their consultant (Natural Systems Design) continues to work on finalizing designs.
- Peshastin Creek Environmental Site Assessment Project – The sponsor (CCNRD) reported that their consultant completed the Phase 1 Environmental Assessment. The report was submitted to the Tributary Committee for review.
- Entiat Fish Passage and Barrier Assessment Project – The sponsor (CCFEG) reported they are preparing for the field season.
- Twisp River Floodplain Left Bank Spring-fed Alcove Restoration Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported that construction was completed on the alcove and crossing at the Coon property. Site planning was completed for riparian restoration. They also completed initial planning for inclusion of several BDA structures to improve alcove complexity.
- Johnson Creek Habitat Restoration Project – The sponsor (TU) did not provide an update this month. This work will occur in 2020.
- Cottonwood Flats Floodplain Restoration Project – The sponsor (CCNRD) reported construction will occur during fall 2020.
- Upper Kahler Stream and Floodplain Project – The sponsor (Yakama Nation; YN) reported that the project is complete. A final report will be available soon.
- Stormy Area "A: Stream and Floodplain Enhancement Project – The sponsor (YN) reported the project will be completed next week. A final report will be available soon.
- Napeequa Side Channel Connection Project – The sponsor (CCFEG) reported they are beginning the permitting process.

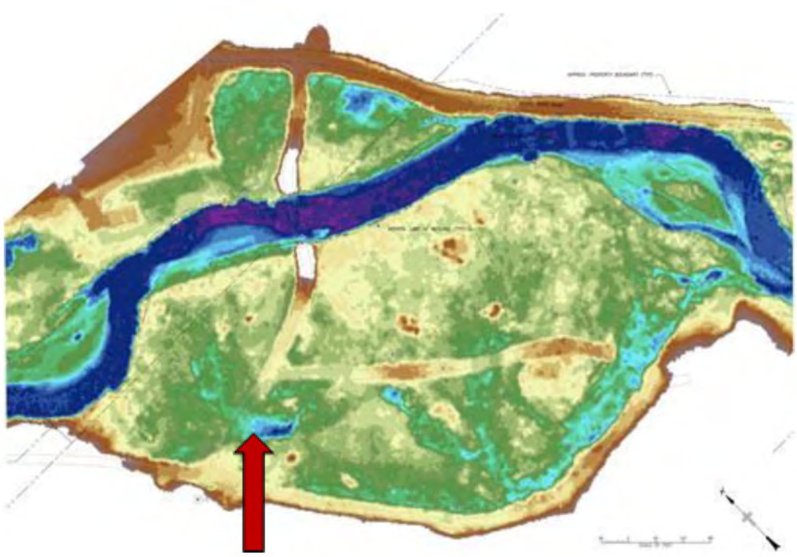
IV. Cottonwood Flats Connection Project Update

Allison Lutes (Chelan County Natural Resources Department) and Nic Truscott (Natural Systems Design) gave a presentation on the status of the Cottonwood Flats Floodplain Connection project (see Attachment 1). They began by providing an overview of the limiting factors and priority actions for the Stillwater Reach within the Entiat River (the proposed project is within the Stillwater Reach). They also provided some historical context on the Cottonwood Flats site and reminded the Committee the purpose and objectives of the proposed reconnection project. Originally, the project was to reconnect the floodplain at 500 cfs, construct a 1,200-foot long side channel, place wood in the side channel to increase structure and roughness, and remove fill and a bridge abutment. The total cost of the project was $600,598. Last year, the Rocky Reach Tributary Committee agreed to contribute $90,090 to the project. Although the SRFB agreed to fund the project, they reduced their contribution by 10% ($51,050). Thus, there is a shortfall in funding for the project. In addition, the landowner (Chelan-Douglas Land Trust) asked the sponsor to consider a design that allows reconnection at lower flows and creates a perennial alcove at the downstream end of the site.

Allison and Nic described the various design considerations including connectivity at 120 cfs, 240 cfs, and 500 cfs; inlet armoring considerations; and a perennial downstream alcove. They shared results from hydraulic modeling and described potential biological benefits from activating the floodplain at different flows. They also described inlet armoring at different flows including the cost and risks associated with armoring at different flows. Finally, they talked about the potential issues with providing a perennial downstream alcove. Because the water table is linked directly with flows in the mainstem Entiat River, it may be difficult to maintain groundwater within the perennial connection. Furthermore, an additional $40,000 will be needed to create a perennial downstream connection.

Allison and Nic then provided the Committee with three alternatives and costs. The first alternative would reconnect the floodplain at 500 cfs and provide a perennial alcove. Under this alternative, the floodplain would be activated for 84 days and no inlet hardening would be needed. This alternative would require an addition $51,000. The second alternative would reconnect the floodplain at 240 cfs and provide a perennial alcove. Under this alternative, the floodplain would be activated for 125 days and wood and/or FESL would be needed to protect the inlet. This alternative would require an additional $170,000. The final alternative would reconnect the floodplain at 120 cfs and provide a perennial alcove. Under this alternative, the floodplain would be activated for 236 days and rock and/or wood would be needed to protect the inlet. This alternative would require an additional $965,000. Allison noted that the landowner's preference is Alternative 2.

Following the presentation, the Rocky Reach Tributary Committee discussed the merits of each alternative and settled on some elements of Alternative 2. That is, they agreed with the 240-cfs connection, and wood and FESL inlet protection, but did not support a perennial alcove or the construction of a channel throughout the floodplain. Instead, they would like to see a feeder channel constructed from the inlet extending to about the first, large depression located near the old roadbed (see figure below). They believe flows exiting the feeder channel will carve out a channel or channels downgradient from the feeder channel. The Committees asked that the sponsor discuss this with their engineers and the landowner to see if this is reasonable and appropriate. If it is reasonable, the sponsor will need to provide a revised budget for the project. If it is not reasonable, the sponsor will need to explain why it is not reasonable and submit a revised budget reflecting a longer side channel (similar to the original design). The Committee will then reevaluate the need for a longer excavated side channel.



Arrow shows the location where the feeder channel would end.

V. Okanagan River Restoration Monitoring Presentation

Kari Alex with the Okanagan Nation Alliance (ONA) gave a presentation summarizing 20 years of the Okanagan River Restoration Initiative (ORRI) (see Attachment 2). Kari discussed the history of development within the Okanagan River valley and described how land uses and development disconnected the floodplain from the river. The river was dammed and channelized resulting in significant loss of habitat and connectivity. In total, 84% of the river was channelized resulting in a 50% reduction in river length, 90% of the riparian vegetation was lost, and most of the instream diversity and floodplain connectivity was lost. As a result, most native fish species declined in abundance and distribution, and exotic species expanded their distribution and increased in abundance. She said the goal of ORRI is to use an ecosystem-based approach to increase floodplain capacity, reconnect the floodplain, improve water quality, and create instream complexity. The program is managed adaptively and relies on collaboration.

Kari described the work conducted near Oliver. Here, enhancement included a large floodplain reconnection project, channel re-meandering, vertical drop structure (VDS) modification, construction of side channels and an amphibian pond, and restoration of a cottonwood meadow. Kari showed photos of these projects before and after enhancement and shared monitoring results, which included channel morphology responses, hydraulic responses, changes in fish habitat, changes in fish abundance and distribution, riparian vegetation responses, and wildlife responses. Importantly, rainbow trout and Chinook salmon returned to the enhanced reach, coverage of macrophytes decreased and Eurasian watermilfoil disappeared from the reach, and macroinvertebrate diversity and richness increased. This reach is now a preferred area for spawning, and egg incubation survival has increased significantly within the reach. Kari noted that although spawning gravels move within the reach, the quantity and quality of the gravels have not changed. In addition, large wood is recruiting to the reach, and side channels are improving overall water quality within the reach. Indeed, the side channels are providing thermal refugia for rainbow trout. She did note that the boulder clusters placed within the reach were not successful as they were eventually buried in the streambed.

Next, Kari talked about the enhancement work near Penticton. In this channelized reach, they added four large spawning beds and placed boulder clusters between spawning beds. The spawning beds were designed to improve spawning habitat for sockeye, kokanee, steelhead, and rainbow trout. They monitored channel morphology, fish habitat, hydraulic responses, and fish responses. They found that the spawning beds are used extensively. In fact, the kokanee bed has been saturated with kokanee since the beds were constructed. In addition, they found that egg incubation survival is similar to undisturbed areas, spawning beds are stable over time, macroinvertebrate diversity increased, habitat diversity increased, Eurasian watermilfoil decreased, and steelhead/rainbow use the boulder clusters. She noted that spawning habitat is still limiting within the Okanagan River.

Lastly, Kari discussed future projects, which include off-channel habitat enhancement, VDS removal, and creation of pool-riffle complexes within the Okanagan River. She also summarized the amount of habitat restored or enhanced within the Okanagan River valley and shared with the Committees information on an upcoming workshop titled, “15 years of Restoring Salmon Habitat.” The workshop will be held in Penticton on 1-2 October 2019.

VI. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from July and August:

   Rock Island Plan Species Account:

- $175.00 to Clifton Larson Allen for Rock Island financial administration in July 2019.
- $1,000.00 to the Upper Columbia Salmon Recovery Board for the 2020 Science Conference.
- $920.33 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project for work in July.
- $775.15 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project for work in July.
- $2,214.20 to Chelan County Treasurer for the Monitor Side Channel Design Project for work in July.

Rocky Reach Plan Species Account:

- $175.00 to Clifton Larson Allen for Rocky Reach financial administration in July 2019.
- $1,000.00 to the Upper Columbia Salmon Recovery Board for the 2020 Science Conference.
- $158.42 to Chelan County Treasurer for the Peshastin Creek RM 8.8 Channel Reconnection – Site Assessment Project for work in July.
- $712.30 to Cascade Columbia Fisheries Enhancement Group for the Entiat Basin Fish Passage and Screening Assessment Project for work in July.
- $1,152.16 to Cascade Columbia Fisheries Enhancement Group for the Napeequa Side Channel Project for work in July.

Wells Species Account:

- $1,000.00 to the Upper Columbia Salmon Recovery Board for the 2020 Science Conference.

2. Several members attended the Peshastin Pumpback Project meeting on 23 July from 10:00 am to noon at the IPID office in Cashmere. They reported that there are major uncertainties associated with O&M and the micro-hydropower facility. They also noted that the sponsor (CCNRD) is unwilling to move forward with the Committees' recommendation to work with the Salmon Recovery Funding Board on changing the scope of the Peshastin Irrigation District Pump Exchange Preliminary Design Project and amend its budget to include the proposed work. Members said they will continue to attend future meetings on the Peshastin Pumpack Project.
3. Members reviewed the Phase 1 Environmental Assessment report on the Peshastin Creek RM 8.8 Project. In sum, the report recommends the following: For the southern (WSDOT site) and northern (BRG quarry) parcels, there are no recognized environmental concerns. For the central portion of the site (Dietrich parcel), there may be some environmental concerns; however, it is anticipated that they can be mitigated during site clean-up. Based on what was observed on site, a Phase II Environmental Assessment is not recommended at this time. The Rocky Reach Tributary Committee directed Tracy Hillman to ask Jennifer Hadersberger (CCDNR) to attend the September meeting to discuss the Phase 1 findings and next steps. Tracy will invite Jennifer to the next meeting. This topic should be discussed jointly with the Tributary Committees and PRCC Habitat Subcommittee. Therefore, Tracy will also coordinate this agenda item with Denny Rohr, Chair of the PRCC Habitat Subcommittee.

4. Steve Kolk (Bureau of Reclamation; BOR) attended the end of the meeting to provide an update on the Sugar Levee Project. He said there has been little progress on the project; however, they (BOR) selected a contractor to help with project design. BOR selected Inter-Fluve, Inc. Steve indicated that there will be a kick-off meeting in September. He also reported that BOR will conduct a value planning study on the IPID Pumpback Project. In addition, they are working with the Yakama Nation on an upper Wenatchee project and assisting with BDA projects.
5. Justin Yeager reported that the Eightmile Creek Fisheries Assessment Project is unlikely to occur this year. According to Justin, WDFW will not have time to set up a contract and hire staff to do the work this year. In addition, it does not appear WDFW will be able to reduce their overhead to 15%.

VII. Next Steps

The next scheduled meeting of the Tributary Committees will be on Thursday, 12 September at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Attachment 1

Presentation by Allison Lutes and Nic Truscott on Cottonwood Flats Project

Stillwater Reach –

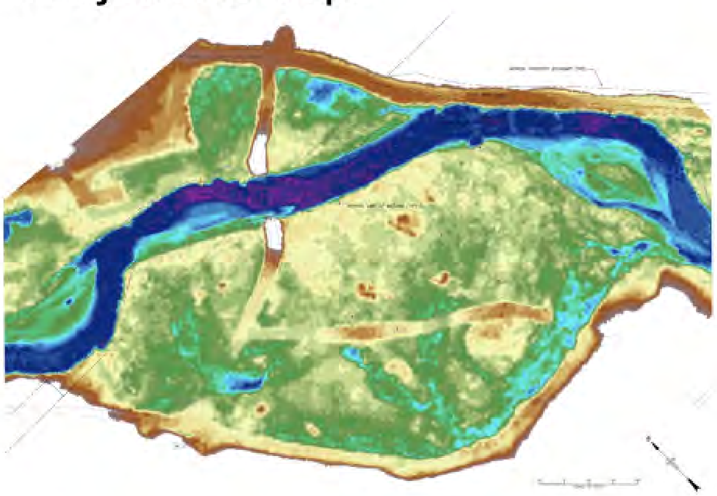
#1 Priority Reach for Restoration Actions in the Entiat River

Ecological Concerns:

#2 Peripheral/Transitional Habitat and

#3 Channel Structure and Form (in stream structural complexity) Priority Restoration Actions

Project Re-cap:

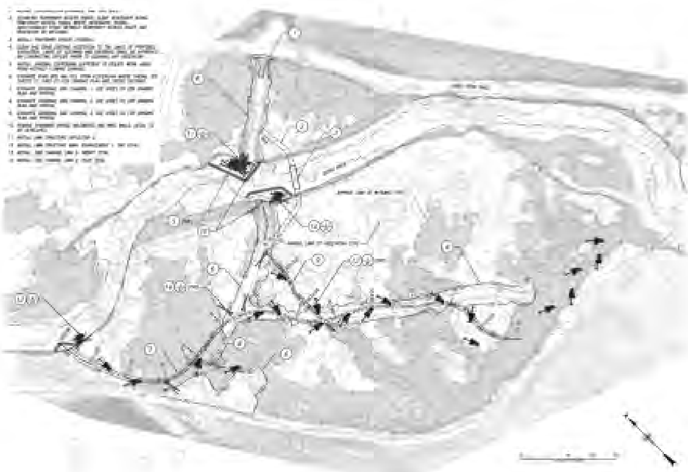


Historical fill violation (1997) on site ~ 5000 c.y. impacting est. 6 acres of wetland

Bridge deck and superstructure were removed in 2017; left bank abutment remains

CCNRD wrote grant for 2018 SRFB round for final design, permitting and construction

Project Re-Cap: 2018 SRFB/TribComm



1. Create a **floodplain side channel (1200' and 6 acres)** for high flow refugia for juvenile spring Chinook and steelhead fry.
   - **500 CFS seasonal connection**
2. Enhance connection between a **downstream alcove area** and the main-stem Entiat river (foraging habitat for spring Chinook and steelhead summer parr)
3. Strategically place main channel **large wood structures and side-channel roughness**
4. Remove 5000~ c.y. of floodplain fill to restore wetland habitat
5. Remove left bank bridge abutment and complete bank restoration

Project Re-Cap & Considerations

2018 SRFB Proposal Budget:

Cottonwood Flats Cost Estimate

Task	SRFB Request	Trib Com	Total
Final Engineering Design	$81,200		$81,200
Engineering Bid Assistance	$2,200		$2,200
Construction (see attached detail)	$348,408	$90,090	$438,498
Engineer Construction Observation	$19,200		$19,200
Cultural Resources	$4,500		$4,500
Permitting*	$9,000		$9,000
Project Management**	$24,000		$24,000
Construction Management and Environmental Compliance	$12,000		$12,000
Landowner time to review designs	$5,000		$5,000
Grant Administration, billings, progress reports	$5,000		$5,000
Total	$510,508	$90,090	$600,598

- Project funded, **budget cut $51,050** (10% by Citizens Committee)
- 2018 SRFB Engineers Estimate did not include earthwork details for downstream alcove. Will present on those details today.

Design Considerations for Discussion:

1. **Design Flows for side-channel (120 CFS vs. 240 CFS vs. 500 CFS)**
   1. Existing conditions
   2. Duration of connection and corresponding biological benefit
   3. **Inlet armoring considerations** for different side channel connections: cost vs benefit vs risk

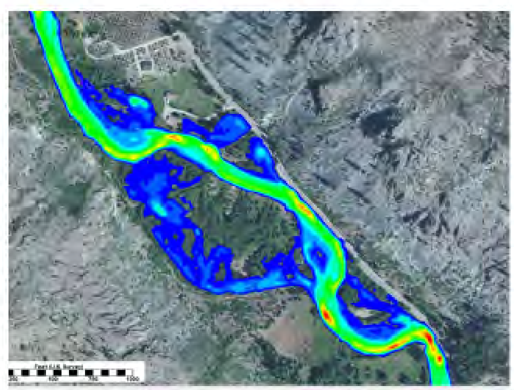
2. **Perennial downstream alcove**

- Groundwater infiltration galleries – possible or not?
- Will the outlet stay open?
- Revised excavation estimate details

6

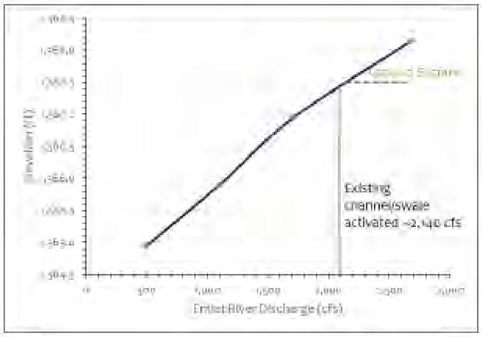
Design Flows for side-channel: Existing Conditions Modeling

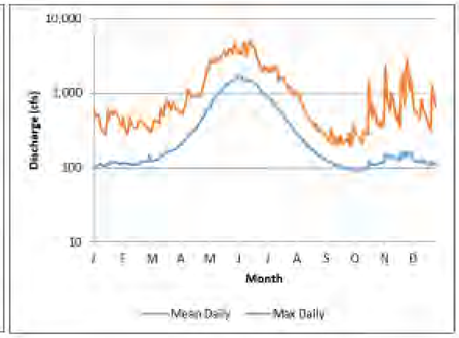
500 cfs



2680 cfs 2 year event

Design Flows for side-channel: Existing Conditions Modeling

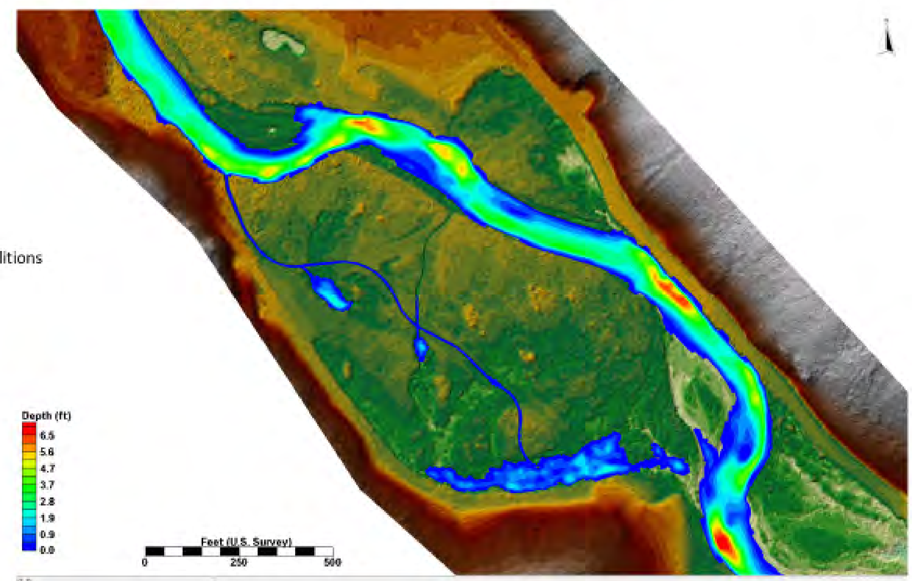




- Over the available period of record (22,550 days ~62 years) there were 400 days where average daily flow exceeded activation threshold… **side channel is active about 1.8% of the time under existing conditions**

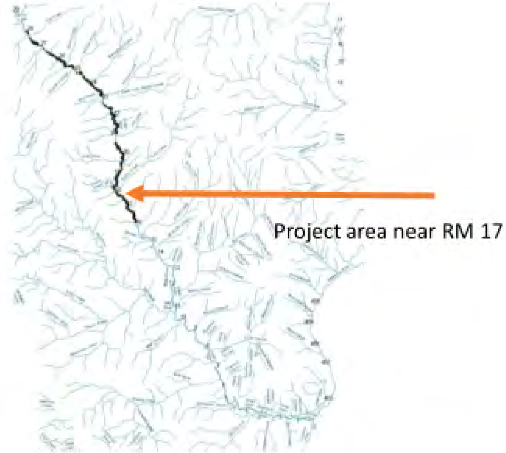
Design Flows for side-channel: Proposed Conditions Modeling: 500 CFS

Figure 1. Proposed conditions modeling at 500 cfs



Design Flows for side-channel: Biological Benefit

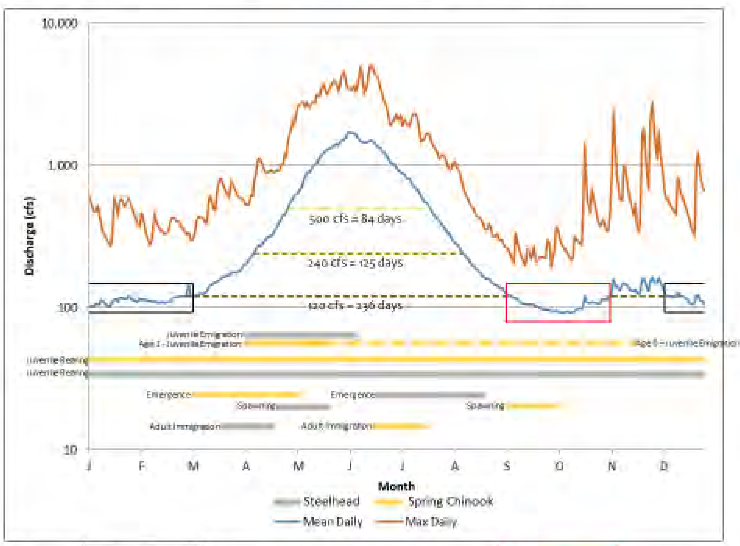
Spring Chinook (pink) and steelhead (yellow) locations in the Entiat River near the project site.



Note that the project area is near the downstream limits of spring Chinook spawning in the Entiat River.

Design Flows for side-channel: Biological Benefit

High Flow Refugia



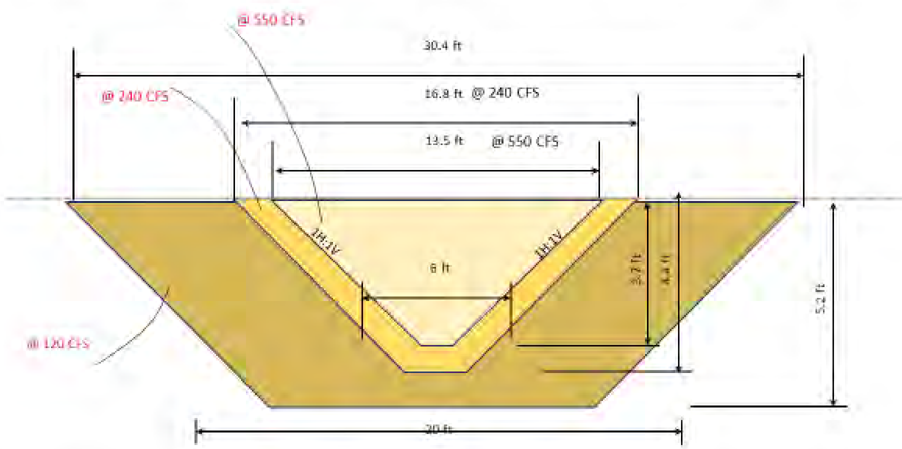
"Winter Flows"
Mean: 125
Median: 118
Min: 101

"Summer Flows"
Mean: 105
Median: 105
Min: 92

Design Considerations for Discussion:

1. **Design Flows for side-channel**
   1. Existing conditions
   2. Duration of connection = biological benefit under different flow scenarios (120 CFS vs 240 CFS vs 500 CFS)
   3. **Inlet armoring considerations** for different side channel connections: Cost vs benefit vs risk
      - 120 cfs
      - 240 cfs
      - 500 cfs
2. **Perennial downstream alcove**
   - Groundwater infiltration galleries – possible or not?
   - Will the outlet stay open?

Inlet Size and Armoring @ Different Side Channel Design Flows

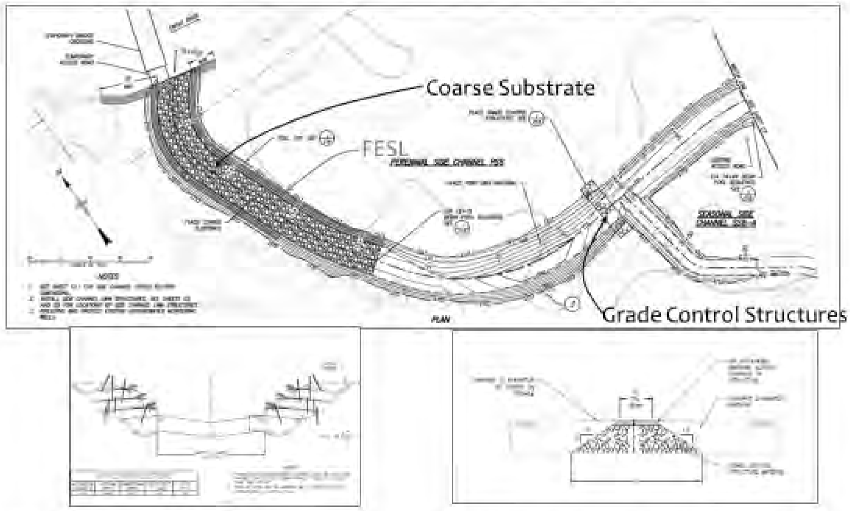


550 CFS Channel Area = 13.5' w X 3.7' d = 36.5 ft^2

240 CFS Channel Area = 16.8' w X ~4.4' d = 54.5 ft^2

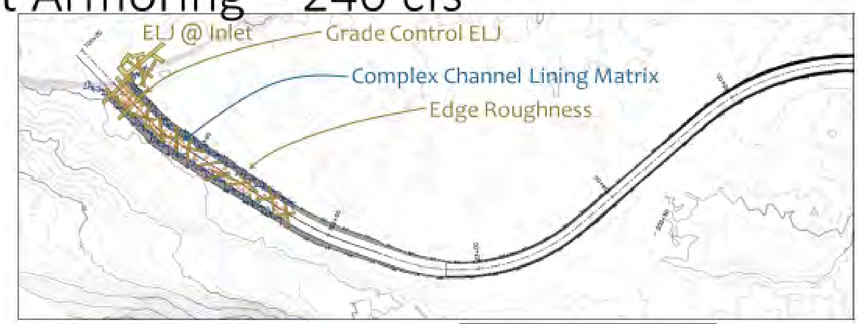
120 CFS Channel Area = 30.4' w X 5.2' d = 144 ft^2

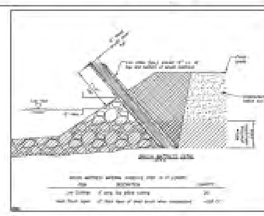
Inlet Armoring – 120 cfs



@ 120 CFS Design Flow the inlet will need more aggressive armoring due to risk in channel avulsion and shear stress risks

Inlet Armoring – 240 cfs





Inlet Hardening, Costs, Risk under Different Side Channel Design Flows

Design Alternative	Activation Flow (cfs)	Days with Surface Water Flow	Channel Excavation (CY)	Inlet Hardening	Construction Cost[1]	Design Certainty	Erosion Risk
120 cfs connection, **rock** inlet	120	236	8,600	Rock	~$1M	High	Moderately Low
120 cfs connection, **wood** inlet	120	236	8,600	Wood	~$925K	Moderately High	Moderate
240 cfs connection, **wood** inlet	240	125	1,500[2]	Wood	~$550K	Moderate	Moderate
500 cfs connection, **no hardening**	500	84	950	None	~$450K	Moderate	Moderate

[1] Construction costs were estimated using similar unit costs of $25/CY for channel excavation incl. haul; Construction Grant Total ~$440K
[2] Approximate excavation volume

Design Considerations for Discussion:

1. **Design Flows for side-channel**
   1. Existing conditions
   2. Duration of connection = biological benefit under different flow scenarios (120 CFS vs 240 CFS vs 500 CFS)
2. **Inlet armoring considerations** for different side channel connections: cost vs benefit vs risk
   - 120 cfs
   - 240 cfs
   - 500 cfs
3. **Perennial downstream alcove**

- Groundwater infiltration galleries – possible or not?
- Will the outlet stay open? What size channel/alcove is appropriate?

Perennial Downstream Alcove: Existing conditions

Alcove habitat

Perennial Downstream Alcove

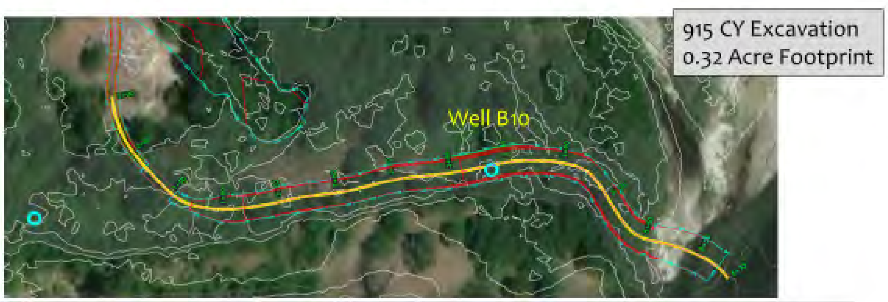
- Is a perennial downstream alcove a possibility?
  - Let's look at GW data from well b10

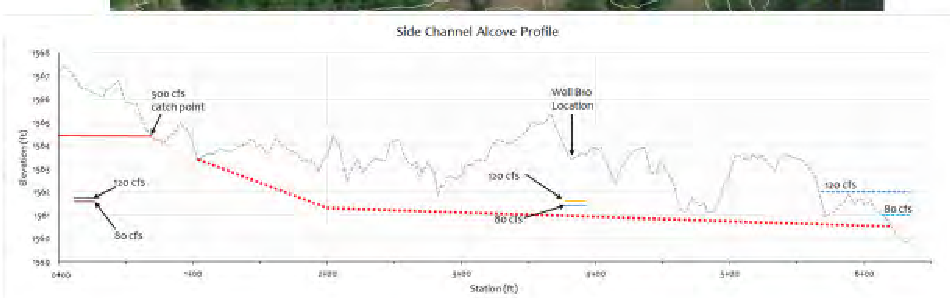
19

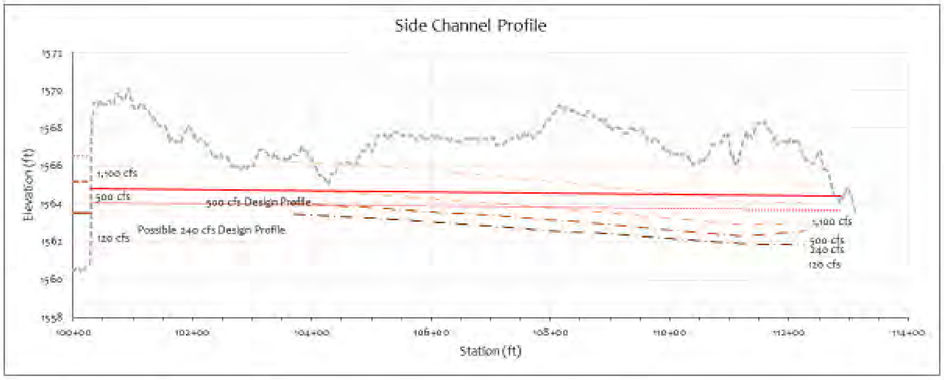
Perennial Downstream Alcove

- Similar to other wells at the site, GWSEs at B10 closely mimic flow fluctuations in Entiat River
  - Fluctuations in Entiat flow (even small) are mimicked in GWSE
  - Doesn't appear that outside sources heavily influence groundwater

Downstream Alcove: groundwater infiltration galleries?







- Side channel profile @ different design flow criteria up to beginning of downstream alcove

Groundwater Data - Takeaways

- GWSEs at all wells closely mimic flow fluctuations in Entiat River
  - Fluctuations in Entiat flow (even small) are mimicked in GWSE
  - Doesn't appear that outside sources heavily influence groundwater as fluctuations in flow and GWSE are visible across range of all flows
- Hydraulic gradient is generally from upstream to downstream with small variations laterally across floodplain
  - GWSEs generally vary approximately 1.6-1.7 ft from the furthest upstream well to the furthest downstream well
  - GWSEs may drop by 1.8-2.0 ft over the entire length of the side channel
- Need to rely upon excavation to have surface water in the side channel

Downstream Alcove – Costs & Uncertainties

- Additional Cost
  - Excavation – 915 CY @ $30/CY
  - Excavation cost likely a bit higher due to wet conditions
  - Site Isolation & Dewatering
  - Additional Access Road/Maintenance
  - Extra Mobilization Cost (Typically 10%)
  - Additional Sales Tax
  - **Estimated Cost Increase ~ $40K**

24

Design Alternatives and Costs:

	Alternative 1	**Alternative 2**	**Alternative 3**
Design Flow	500 CFS with perennial alcove	240 CFS with perennial alcove	120 CFS with perennial alcove
Days of connection	84 days of activation	125 days	236 days
Inlet Protection	No hardening	Wood/FESL	Rock option or Wood option
Additional Modeling/Engineering Costs	Modelling completed;60% grading designs/cross-sections and profiles; final designs funded	Modeling not completed; all new grading designs, sheets, cross-sections, and profiles	Modeling completed; all new grading designs, sheets, cross-sections, and profiles
Additional Cost	$51k - 10% cut from citizens committee **= $51k total**	$51k cut from citizens + additional 120k for engineering and construction **= $170k total**	$51k cut from citizens + additional 495k for engineering and construction **= $965k total**

Project Timeline

Task	Timeline
Contracting with RCO	Jan. 31, 2019
Hire Engineering Design Contractor	Feb. 2019
River left bio-engineering design	Fall 2019
River left voluntary bank restoration	Fall 2019
River right 80% design	Fall 2019
Secure permits for river right floodplain restoration	Spring 2020
Final design	Spring 2020
Bid to hire restoration contractor	June 1, 2020
Floodplain restoration river right	Oct 31, 2020

ORRI Oliver
Created Amphibian
Ponds (2014)

ORRI Oliver

GOALS 2018:

- Create a Cottonwood meadow.
- inundated at spring flows
- drain completely for no stranding of indigenous fish

ORRI monitoring

ORRI Oliver

- floodplain reconnection 2008
- re-meander 2009
- VDS13 modifications 2013
- side channel 2013
- Amphibian pond habitat 2014
- Cottonwood meadow 2018

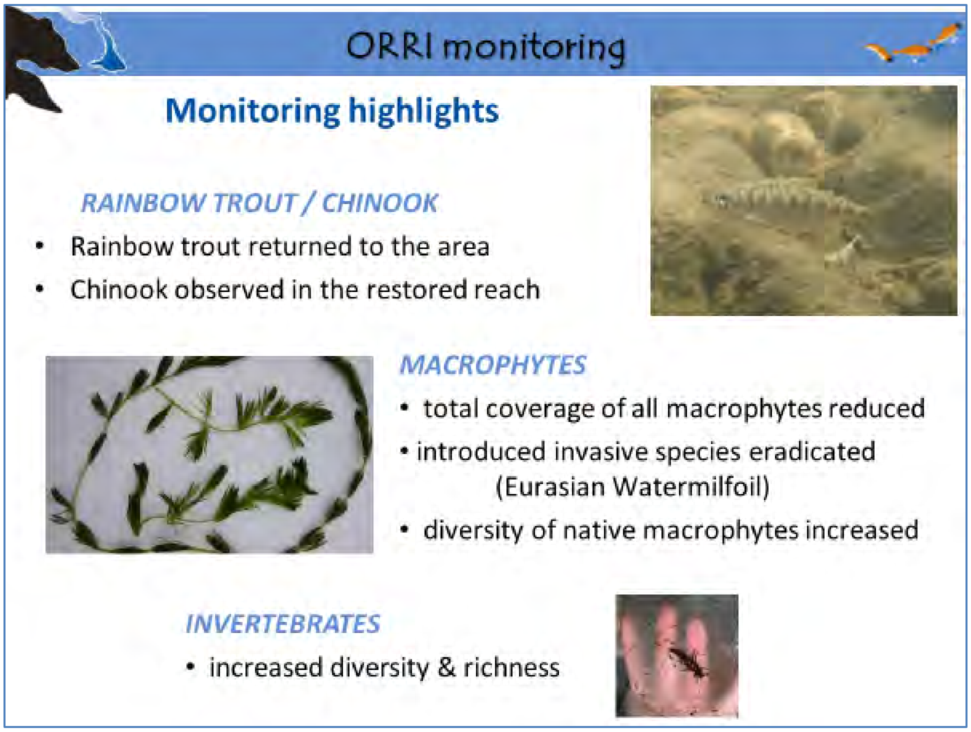
ORRI Penticton

- spawning beds 1 & 2 – 2014
- Spawning bed 3 - 2015
- Spawning bed 4 - 2018

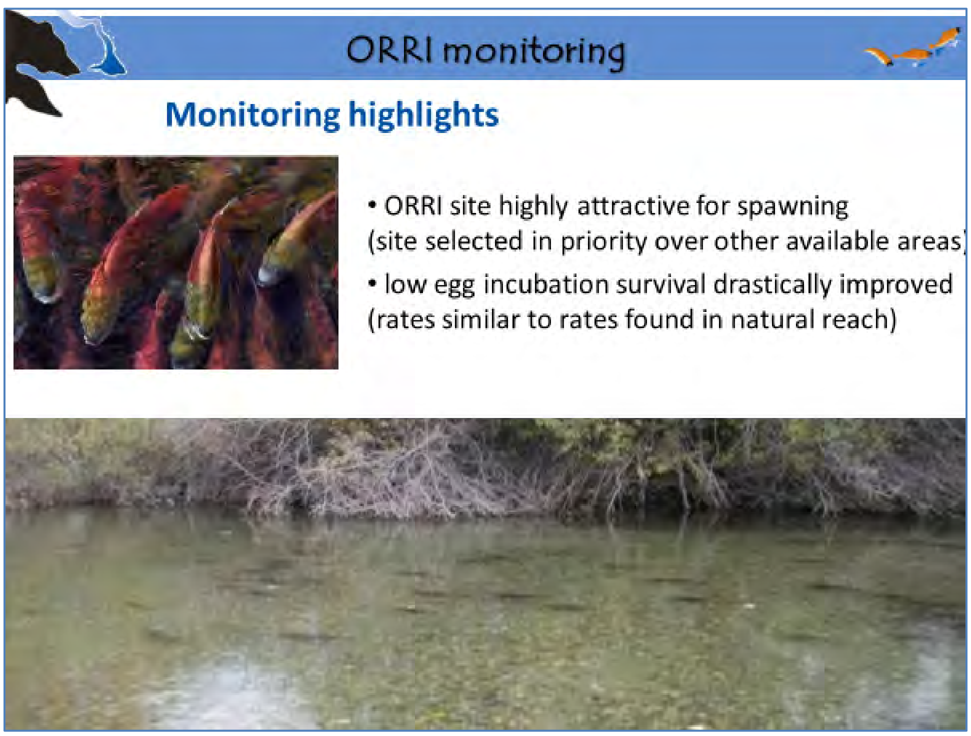
Monitoring 2008- 2018

- Channel morphology
- Hydraulic response
- Fish habitat & fish response
- Riparian response
- Wildlife response

Monitoring 2014- 2018



ORRI monitoring
Monitoring highlights
RAINBOW TROUT / CHINOOK
• Rainbow trout returned to the area
• Chinook observed in the restored reach
MACROPHYTES
• total coverage of all macrophytes reduced
• introduced invasive species eradicated (Eurasian Watermilfoil)
• diversity of native macrophytes increased
INVERTEBRATES
• increased diversity & richness



ORRI monitoring
Monitoring highlights
• ORRI site highly attractive for spawning
(site selected in priority over other available areas)
• low egg incubation survival drastically improved
(rates similar to rates found in natural reach)

ORRI monitoring

HABITAT FEATURES

- LWD increased overtime (natural transport)
- boulders are loss overtime (embedded in gravel); no trout observed

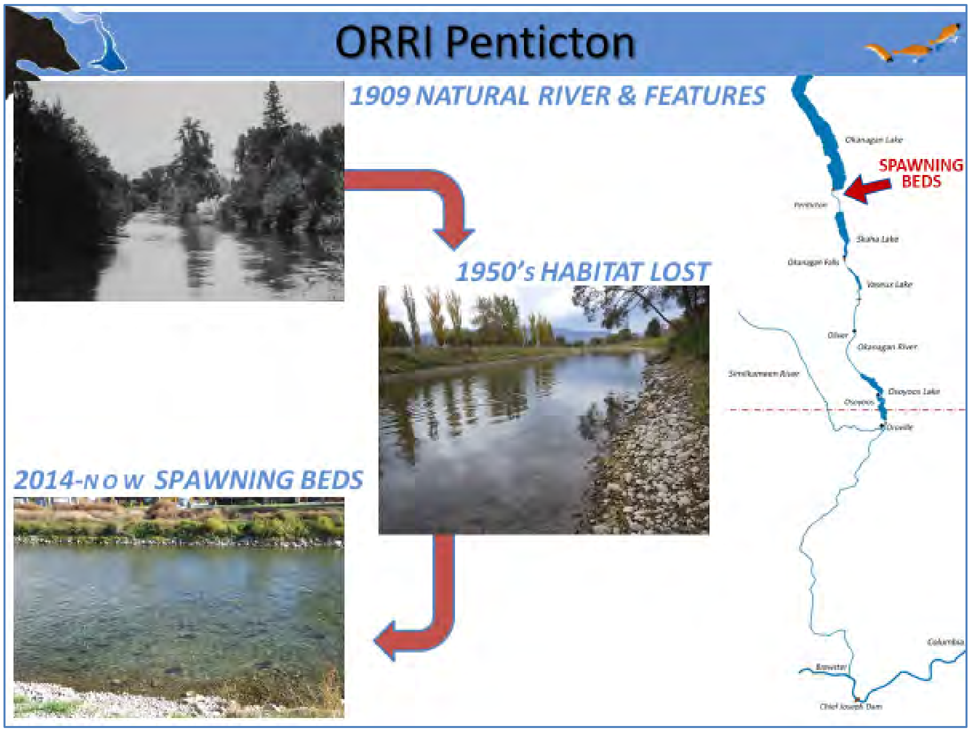
HABITAT REFUGE

Phase II side channel acted as a water quality refuge during a high turbidity event

ORRI monitoring

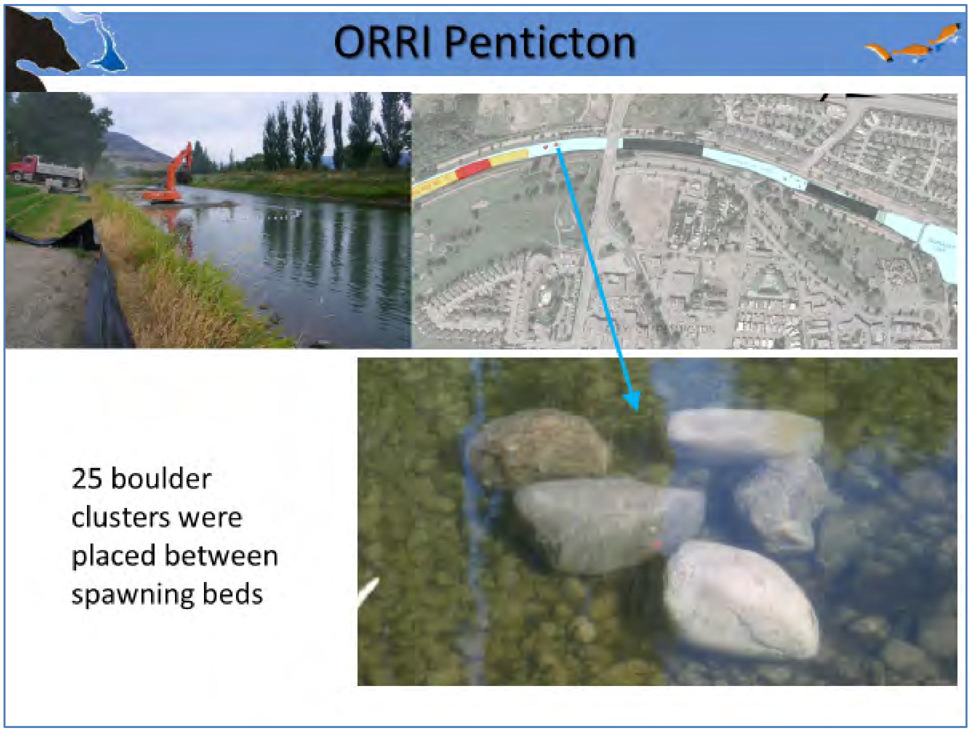
ORRI Oliver - what we learned and have used

- The Froude numbers Sockeye spawners selected was built into Penticton spawning beds successfully.
- Spawning gravels moved but the total area for spawning remains the same and the spawning gravels are retained.
- We continue to learn about the redd areas needed for Sockeye pairs.
- Learned from side channel that the summer flows are too warm but that spring flow of the side channel is utilized by O.mykiss. We would like to test for use by Chinook.
- The boulder clusters we placed all dug themselves into the bed. The design was fixed for boulder clusters in the Penticton channel.
- Tested hydraulic features that can be created to eradicate milfoil.
- Used all the flow and floodplain inundation data to build the cottonwood meadow.

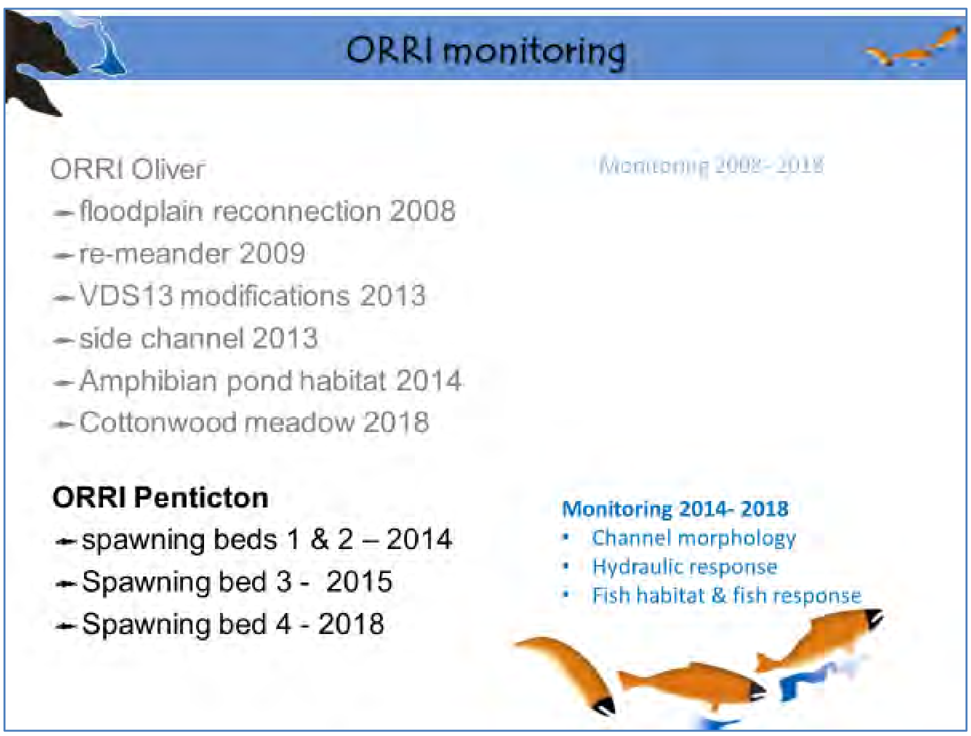


ORRI Penticton

Spawning Bed	Year built	Targeted species	Design gravel size	Bed length	Created area
Bed No.1	2014	Chinook	50-100 mm (D_{50}= 75 mm)	20 m (built)	480 m^2
		Sockeye & Steelhead	25-75 mm (D_{50}= 50 mm)	153 m (built)	3,400 m^2
Bed No.2	2014	Sockeye & Steelhead	25-75 mm (D_{50}= 50 mm)	163 m (built)	3,600 m^2
Bed No.3	2015	Sockeye & Steelhead	19-75 mm (D_{75}= 50 mm)	200 m (built 3A & 3C)	4,040 m^2
		Kokanee & Rainbow	19-50 mm (D_{50}= 25 mm)	70 m (built 3B)	1,460 m^2
Existing Kokanee Bed	1986; enhanced in 2018	Kokanee & Rainbow	6-38 mm (1985 design) 13-50 mm (enhancements)	160 m	4,320 m^2
Bed No.4	2018	Sockeye & Steelhead	25-75 mm (D_{50}= 50 mm)	350 m	6,250 m^2
		Kokanee & Rainbow	25-50 mm (D_{50}= 35 mm)	310 m	5,520 m^2



ORRI Penticton
25 boulder clusters were placed between spawning beds



ORRI monitoring
ORRI Oliver
- floodplain reconnection 2008
- re-meander 2009
- VDS13 modifications 2013
- side channel 2013
- Amphibian pond habitat 2014
- Cottonwood meadow 2018
Monitoring 2008 - 2018
ORRI Penticton
- spawning beds 1 & 2 – 2014
- Spawning bed 3 - 2015
- Spawning bed 4 - 2018
Monitoring 2014- 2018
• Channel morphology
• Hydraulic response
• Fish habitat & fish response

ORRI monitoring

Monitoring highlights

- Kokanee utilized Bed No.3 close to maximal capacity every year.
- Spawning habitat is still limited.
- Egg incubation survival rates similar to rates found in Natural & Semi Natural sections.
- Beds stable overtime (high freshet flows)
- Benthic invertebrate diversity has increased.

ORRI monitoring

Monitoring highlights

- Habitat diversity increased. Glides decreased (replaced by riffles and pools).
- Invasive Eurasian watermilfoil drastically decreased with construction at beds.
- *O. mykiss* observed using the boulders in 2014, 2015 and 2017

ORRI monitoring

ORRI Penticton- what we learned and have used

- The Froude numbers Sockeye spawners select is 0.31 ± 0.1. We continue to refine selection by spawners over a range of flows (6cms – 12 cms) and a range of population sizes for both SK and KO.
- We continue to learn about the redd areas needed for Sockeye pairs and how this interacts with Kokanee spawners (hybridization issues).
- Spawning gravels do not move in this reach and the flushing rates of fine sediments needs to continue to be monitored.
- Use of boulder clusters needs to be assessed.
- Continue testing hydraulic features that can be created to eradicate milfoil.
- Bed 4 is new and needs to be monitored for use and stability.

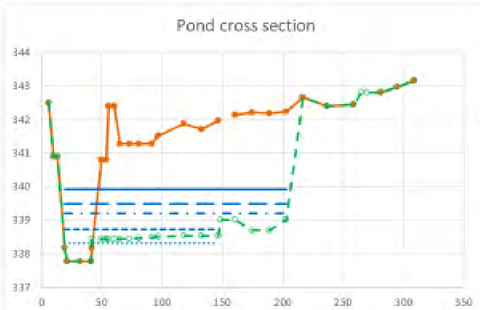
Future projects

- k'əmcənitkʷ
  - off-channel habitat
- VDS removal
  - Bed re-profile with pools & riffles

k'əmcənitkʷ

GOALS:

- restore floodplain habitats,
- create Chinook rearing pond,
- restore fish-free floodplain, and
- riparian habitat for aquatic wildlife.



VDS removal & bed re-profile

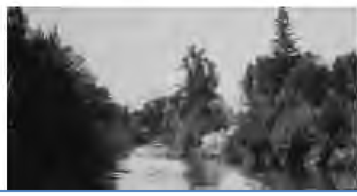
During channelization of this entire river reach reduced fish habitat features & river diversity. Four vertical drop structures (VDS 14 to 17) were added to stabilize the river bed under the increased slope of the channel straightening.

Project goal

- Create pool-riffle complexes
- Without impacting flood flows
- Maintain bed stability
- Salmonid spawning conditions are created at riffle structures.

ORRI

Habitat created via ORRI		Length /areas
2008	setback dyke	1,200m
	floodplain reconnected	15,000m²
2009	Re-meander	500m
	pool-riffle habitat added	11,175m²
	spawning areas	9,100m²
2013	VDS13 modifications – spawning area	4,575m²
2013	side channel	5,239m²
2014	wetland features - salamander pond	200m²
	wetland features - spadefoot pond	60m²
	floodplain - boulder, Woody features	400m²
2014	Penticton channel spawning bed 1& 2	Sockeye 7,074m² Chinook 430m²
2015	Penticton Channel spawning bed 3	Sockeye 7,154m² Kokanee 1,477m²
2018	Pentiction Channel spawning bed 4	Sockeye 6,250m² Kokanee 5,520m²



Campbell Biology text book

Save the Date: October 1st & 2nd, 2019
WORKSHOP: 15 YEARS OF RESTORING SALMON HABITAT
The Okanagan Nation Alliance in collaboration with many project partners have been successfully restoring spawning and rearing habitat for salmon in the Okanagan Basin for over 15 years. Traditional Ecological Knowledge, best management practices, measured stream geometry and natural habitat features have guided these restoration works. This workshop will teach the math behind the stream analysis and hydraulics that directed the restoration designs and describe the planning, construction, monitoring methods and results.
Workshop outline:
• Teach the calculations behind stream analysis, river hydraulics and pool-riffle design.
• Field visits to several habitat restoration projects.
• Show the process of implementing a river restoration project from beginning-to-end (planning, designs, construction, and adaptive management).
• Explain the projects monitoring methods and results.
• Discussion and poster sessions: hydraulic modelling, fish habitat diversity, spawning beds, riffles, fish passage at barriers, floodplain reconnection, wetland restoration.
Course targeted to but not limited to:
• Those designing or reviewing river instream works, particularly for salmon habitat.
• Environmental scientists and project managers (Biologists, Engineers, Geomorphologists, Hydrologists and Fisheries Technicians).
Presenters:
• Kari Alex, Camille Rivard-Sirois & Zoe Eyjolfson. Okanagan Nation Alliance Fisheries Department
• Robert Newbury. Newbury Hydraulics
Course details:
• Date: October 1st & 2nd, 2019
• Location: En'owkin Centre, Penticton, BC, Canada
• Registration fees: $750/person
For more information or early seat reservation, please contact:
Zoe Eyjolfson, Okanagan Nation Alliance

THANK YOU - LIM LIMPT

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 12 September 2019

Members Present:	Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Catherine Willard (Chelan PUD), Justin Yeager (NOAA Fisheries)[1], and Tracy Hillman (Committees Chair).
Members Absent:	Brandon Rogers (Yakama Nation)[2]
Others Present:	Becky Gallaher (Tributary Project Coordinator), Allison Lutes (Chelan County Natural Resources Department), John Soden (Natural Systems Design), and David Morgan (Chelan-Douglas Land Trust).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 12 September 2019 from 10:00 am to 12:00 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with the addition of a three-year review of the HCP Tributary Committees Chair.

II. Review and Approval of Meeting Minutes

Tributary Committees members reviewed and approved the 8 August 2019 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- Barkley Irrigation – Under Pressure Project – The sponsor (Trout Unlimited; TU) reported the bids for Phase II piping are due on 27 September with construction set to start in early October. The project should be completed by 31 March 2020. Construction on the Barkley pump station is scheduled to start at the end of September with a completion date of 31 March 2020. The sponsor indicated that they completed three of the five satellite wells in August. The others should be completed in September. They will then conduct pump tests.
- Icicle Boulder Field Project – The sponsor (TU) reported they made significant progress on permits and have received the 404 and 401 permits. The Army Corps of Engineers, NMFS, and USFWS have also made their determinations. The Hydraulic Project Approval (HPA) permit has been submitted for review. The sponsor hopes to have the bid documents completed this month,

[1] Justin called into the meeting.
[2] Brandon provided his votes and input on decision items following the meeting.

which will allow a bid walk during low flow conditions. Kate Terrell reported that the statement of agreement (SOA) regarding anadromous fish management in the Icicle Creek watershed was signed by the YN, CCT, WDFW, NOAA Fisheries, and USFWS. Jeremy Cram indicated that there remain a few obstacles that need to be addressed before the project can be implemented.

- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – This project is complete. The sponsor (Washington Department of Fish and Wildlife; WDFW) will provide the next annual report on 31 December 2019.
- Beaver Fever Project – The sponsor (TU) reported they conducted site visits within several Wenatchee tributaries where they conducted both pre- and post-project data collection. Site recon was also conducted in the Entiat in preparation for work with the Forest Service during the next field season.
- Methow Basin Barrier Diversion Assessment Project – The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) did not provide an update this month.
- Derby Creek Fish Passage Project – The sponsor (CCFEG) reported that WDFW is working with the Army Corps of Engineers to finalize permits.
- Chiwawa Nutrient Enhancement Project – The sponsor (CCFEG) reported they are preparing for the field season.
- Monitor Side Channel Design Project – The sponsor (Chelan County Natural Resources Department; CCNRD) reported that the preliminary design is complete. They are also working with the landowners to secure access for construction.
- Peshastin Creek Environmental Site Assessment Project – This project is complete. The sponsor (CCNRD) will discuss results and next steps with the Committees in October.
- Entiat Fish Passage and Barrier Assessment Project – The sponsor (CCFEG) reported field work will be completed by the end of September with draft results available in October.
- Twisp River Floodplain Left Bank Spring-fed Alcove Restoration Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported they initiated the permitting process for the beaver dam analog (BDA) structures.
- Johnson Creek Habitat Restoration Project – The sponsor (TU) did not provide an update this month. This work will occur in 2020.
- Cottonwood Flats Floodplain Restoration Project – The sponsor (CCNRD) reported construction will occur during fall 2020.
- Upper Kahler Stream and Floodplain Project – The sponsor (Yakama Nation; YN) reported construction is complete. As-builts will be completed by the end of September and site planting is scheduled for the end of October.
- Stormy Area “A: Stream and Floodplain Enhancement Project – The sponsor (YN) reported construction is complete. As-builts will be completed by the end of October.
- Napeequa Side Channel Connection Project – The sponsor (CCFEG) reported they began cultural resources evaluations. A site visit with permitting agencies is planned for late October.

IV. Cottonwood Flats Connection Project Update

Allison Lutes (Chelan County Natural Resources Department) and John Soden (Natural Systems Design) gave a presentation on the Cottonwood Flats Floodplain Connection project (see Attachment 1). This presentation is a follow up visit with the Committees based on feedback the Committees provided to the sponsor regarding reconnecting the Cottonwood Flats floodplain with the Entiat River. In August, the Committees supported the 240-cfs connection, and wood and FESL inlet protection, but did not support a perennial alcove or the construction of a channel throughout the floodplain. Instead, they recommended the development of a pilot channel extending from the inlet to about the first large depression located near the old roadbed. The Committees believe flows exiting the pilot channel will carve out a channel or channels downgradient from the pilot channel. In August, the Committees asked the sponsor to discuss the Committees' recommendation with the sponsor's engineers and the landowner (CDLT) to see if the Committees' recommendation is reasonable and appropriate. The presentation today is a result of discussions the sponsor had with their engineers and the landowner.

Allison and John began by briefly describing the recommendations provided by the Tributary Committees in August. They also reviewed the goals of the project, which are to create a floodplain side channel, activate the floodplain at certain flows, remove the fill/gravel road prism, remove concrete bridge abutments, strategically place large wood structures, and balance construction impacts with costs with overall project benefits. John then described the analyses they conducted to evaluate the "Light Touch," "Light Touch +," and "Full Channel" approaches. The Light Touch approach was the approach recommended by the Committees in August. The Light Touch "+" approach is the Light Touch with the addition of extending the pilot channel farther into the floodplain. The Full Channel approach is similar to the original proposed approach and includes extending the side channel farther down the floodplain. Analyses of the three approaches included modeling composite water surface and groundwater surface elevation maps at different stream flows.

Based on their analyses, they identified some potential concerns with the Light Touch approach, including ponding upstream of existing high points on the floodplain, flow-through connection is unlikely to occur until >1,100 cfs, uncertainty regarding formation of a preferential flow path, and the approach does not appear to achieve project objectives. In contrast, the Light Touch "+" approach will extend the pilot channel past the initial low spot and create a connection to low-lying floodplain channels. Under this approach, ponding will likely occur in upstream alcoves, flow-through connection should occur at 1,100 cfs, and preferential flow paths will form for a portion of the channel but there is uncertainty if the flow paths will form in the downstream portion of the floodplain. Unlike the Light Touch approaches, the Full Channel approach will create ponding only at the downstream alcove, flow-through connection occurs at 500-800 cfs, preferential flow paths will exist immediately, and groundwater will be expressed in the downstream end of the channel at flows >500 cfs. This approach maximizes achievement of project objectives given design guidance. John showed the following table that compares the three approaches.

Objective	Light Touch	Light Touch "+"	Full Channel
Flow-through Connection	Flow-through connection will not occur until ~1,100 – 1,500 cfs (> Q1) Ponding likely to occur upstream of existing depression	Flow-through connection occurs ~1,100 cfs Very low velocities Ponding likely to occur in alcove for lower flows >800 cfs	Flow-through connection occurs ~500-800 cfs Ponding likely to occur in downstream alcove for lower flows >500 cfs
Design Certainty	Preferential flow paths may or may not form	Preferential flow paths created for portion of channel Downstream portion may or may not form	Preferential flow paths created from Day 1

Objective	Light Touch	Light Touch "+"	Full Channel
Meets Project Objectives	Overall – does not achieve project objectives	Partially meets project objectives	Overall – maximizes achievement of project objectives given past/present design guidance

Committee members questioned the uncertainty associated with establishment of flow-through paths. They agreed that ponding will occur; however, as water continues to flow into the side channel, the water will eventually overtop the high points on the floodplain and then cut a flow path or flow paths through the floodplain. Tom Kahler suggested that if the high points are a concern, then simply knock down those high points to help flow paths develop (referred to as the "Kahler Knock-Down" approach). This does not mean constructing channels. Rather, it is a cost-effective, low-disturbance approach to guiding development of flow paths. Members agreed with this approach. John Soden and Dave Morgan also found value in this approach.

Tracy reminded the Committees that ponding can create entrapments for ESA-listed fish. This is less of a concern if the entrapments are connected with groundwater. He said there are a number of studies, including studies in the Methow, that demonstrate salmonids grow and survive well in entrapments connected with groundwater. The concern here is the upstream entrapments will not be connected with groundwater during most of the year. Thus, there is a real concern that stranding will occur, resulting in the potential loss of ESA-listed fish. Jeremy agreed and said monitoring will be needed to document potential stranding. If stranding is likely to occur, we need to be ready to salvage fish from entrapments that are likely to dewater. Members discussed the need to monitor the project and if necessary, salvage fish from entrapments. They suggested the use of drones to monitor physical changes and mark-recapture studies to evaluate fish response. Tracy said there may be cost-sharing opportunities with the Salmon Recovery Funding Board, who will be calling for proposals to evaluate floodplain reconnection projects with remote sensing.

Dave Morgan noted that his preference is to have a perennial side channel, because monitoring data from the Entiat River suggest that parr habitat, especially winter parr habitat, appears to be limiting in the Entiat. A perennial side channel would provide habitat for the limiting life stage. However, Dave said he also supports the Committees recommendation, because there is no infrastructure to protect and therefore it provides a unique opportunity to evaluate a light touch approach. John Soden agreed and said the Committees can monitor the reconnection project and, if necessary, implement actions to help with channel evolution and to reduce stranding. Given that development of flow paths could take several years (depending on high-flow events), Allison asked how long the Committees are willing to risk the possible standing of ESA-listed species. Members said they would be willing to wait about five years before implementing actions to help with channel evolution. Jeremy said the risk could be reduced if monitoring and salvage work are conducted annually.

Following the presentation, and after Allison, John, and Dave left the meeting, the Committees discussed the project further and agreed to support the Light Touch with the Kahler Knock-Down approach. Jeremy said he can support a short-season, light-touch approach with sufficient adaptive management and fish stranding monitoring, but he did not think the value of the project is maximized if the side channel is only activated for roughly three months during the highest flow conditions. He is also concerned with the high risk of stranding given the disconnection between surface water and groundwater. He added that raising the stage of the mainstem or using an ELJ or constructed riffle to divert flows into the side channel should be considered and has been considered in the past, but the reasons for moving away from these options are unclear. More information on engineering feasibility, avulsion risk, and landowner concerns is needed and perhaps the only thing that should be done on this site is fill removal.

Because Brandon was unable to attend the meeting, Tracy spoke with Brandon following the meeting. After briefing Brandon on the presentation and the Committees' recommendation, Brandon reluctantly supported the recommendation. Brandon and Jeremy share some of the same concerns. Like Jeremy, Brandon is concerned with stranding. Brandon believes stranding can be avoided with the implementation of the Full Channel approach. In addition, Brandon is concerned with the side channel not being connected with groundwater and with the lack of large wood within the side channel or whatever channel forms. Large wood would provide some stability and a long-term (~20 years) source of cover for juvenile fish. Finally, because of the low gradient floodplain, Brandon is concerned with sediment deposition.

The Committees directed Tracy to inform the project sponsor that the Committees support the Light Touch with the Kahler Knock-Down approach. That is, the preferred approach is to construct a pilot channel as identified under the "Light-Touch" approach and to "knocking down" high spots to aid channel formation down-gradient from the pilot channel. Given the absence of any infrastructure that needs protecting, this approach should reduce costs and allow the water to do most of the work. Importantly, this approach should protect most of the existing riparian vegetation on the floodplain.

V. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from August and September:

   Rock Island Plan Species Account:

   - $50.00 to Clifton Larson Allen for Rock Island financial administration in August 2019.
   - $161.41 to Cascade Columbia Fisheries Enhancement Group for the Derby Creek Fish Passage Project for work in August.
   - $1,152.80 to Cascade Columbia Fisheries Enhancement Group for the Chiwawa Nutrient Enhancement Project for work in August.
   - $14,419.65 to Chelan County Treasurer for the Monitor Side Channel Design Project for work in August.

   Rocky Reach Plan Species Account:

   - $50.00 to Clifton Larson Allen for Rocky Reach financial administration in August 2019.
   - $55.21 to Chelan County Treasurer for the Peshastin Creek RM 8.8 Channel Reconnection – Site Assessment Project for work in August.
   - $6,190.11 to Cascade Columbia Fisheries Enhancement Group for the Entiat Basin Fish Passage and Screening Assessment Project for work in August.
   - $1,033.58 to Cascade Columbia Fisheries Enhancement Group for the Napeequa Side Channel Project for work in August.

2. Chris Fisher reported that Okanagan Nation Alliance will be working on providing fish passage at Penticton Dam this fall. They will begin fishway construction in October. They intend to collect adult sockeye salmon within the Okanogan River (Penticton Channel) and tag them with PIT tags and spaghetti tags. They will then track them as the fish migrate upstream from the dam.

3. Tom Kahler reported that the Tributary Committees conducted an evaluation of the HCP Tributary Committees' Chair (Tracy Hillman). Tom said the PUD representatives polled all the members by email offering opportunity to reply directly or request a conference call or meeting to discuss the Chair's performance. All members replied via email that they were pleased with the Chair's performance and wanted Douglas PUD and Chelan PUD to retain Tracy's services for another three-year term. Tracy agreed to serve as the Chair for the Wells, Rocky Reach, and Rock Island Tributary Committees for another three years.
4. Tracy Hillman reminded members that Jennifer Hadersberger (CCNRD) will attend the October meeting to discuss Phase 1 Environmental Assessment results and next steps on the Peshastin Creek RM 8.8 Project. This topic will be discussed jointly with the PRCC Habitat Subcommittee. Therefore, Tracy will also coordinate this agenda item with Denny Rohr, Chair of the PRCC Habitat Subcommittee.

VI. Next Steps

The next scheduled meeting of the Tributary Committees will be on Thursday, 10 October at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Attachment 1

Presentation by Allison Lutes and John Soden on Cottonwood Flats Project

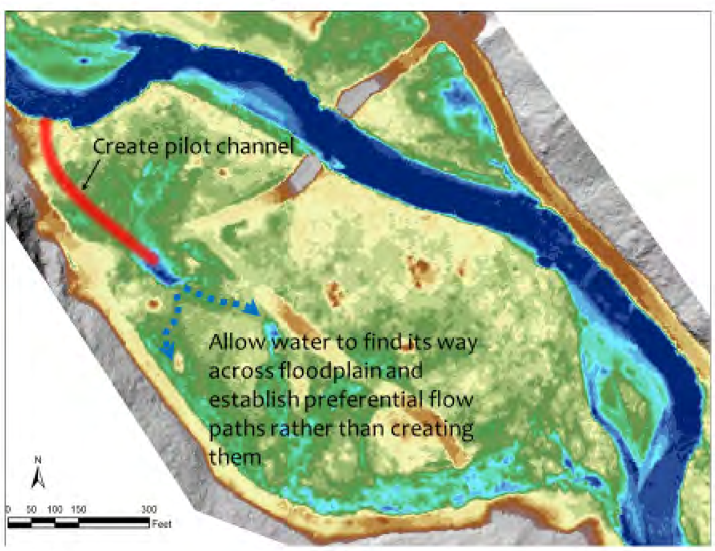
Design Take-Aways August 2019 Meeting:

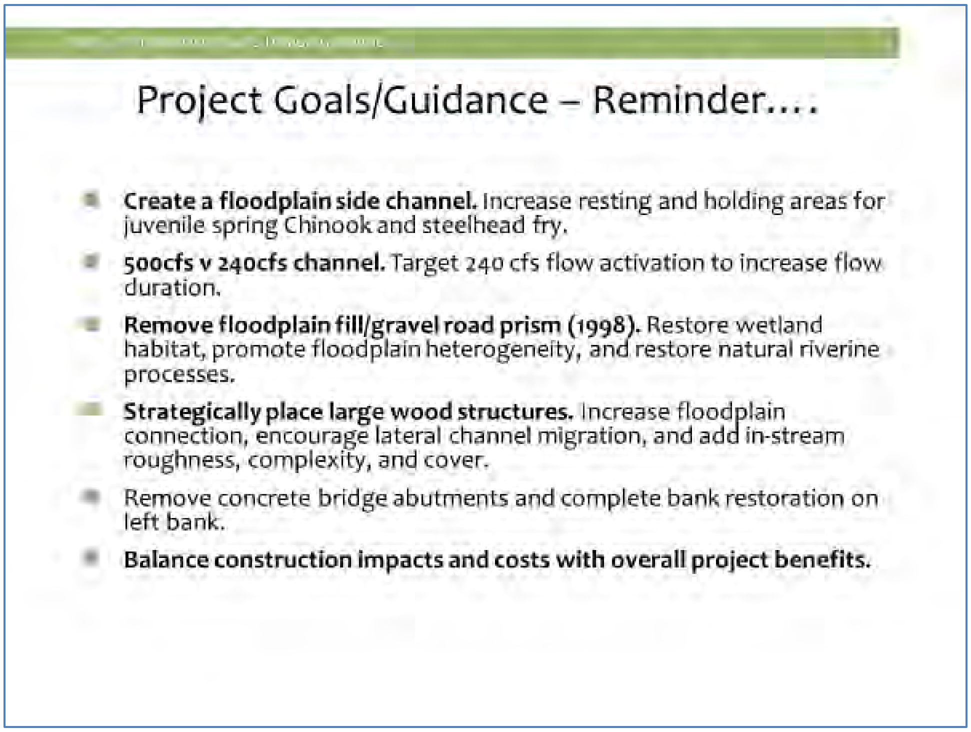
1. Design Flows for side-channel and armoring considerations:
   - 120 CFS with rock inlet armor
     - High risk of channel avulsion; not worth risk and additional cost for aggressive rock armoring (~1million construction)
   - **240 CFS wood inlet (preferred)**
     - Wood inlet armoring; moderate cost increase ($100k additional); with additional 40 days of flow activation and increased biological benefit; preferred by landowner
   - 500 CFS no armor
     - No armoring needed; 84 days of activation; original design flow; reduced excavation required

2. Perennial downstream alcove **(not preferred)**
   - Natural deposition area; uncertainty whether outlet will remain open
   - Concerns regarding excavating existing intact wetland/beaver dam habitat
   - Will need to rely on excavation to have surface water in downstream alcove;
   - Concerns regarding over excavation draining the wetland

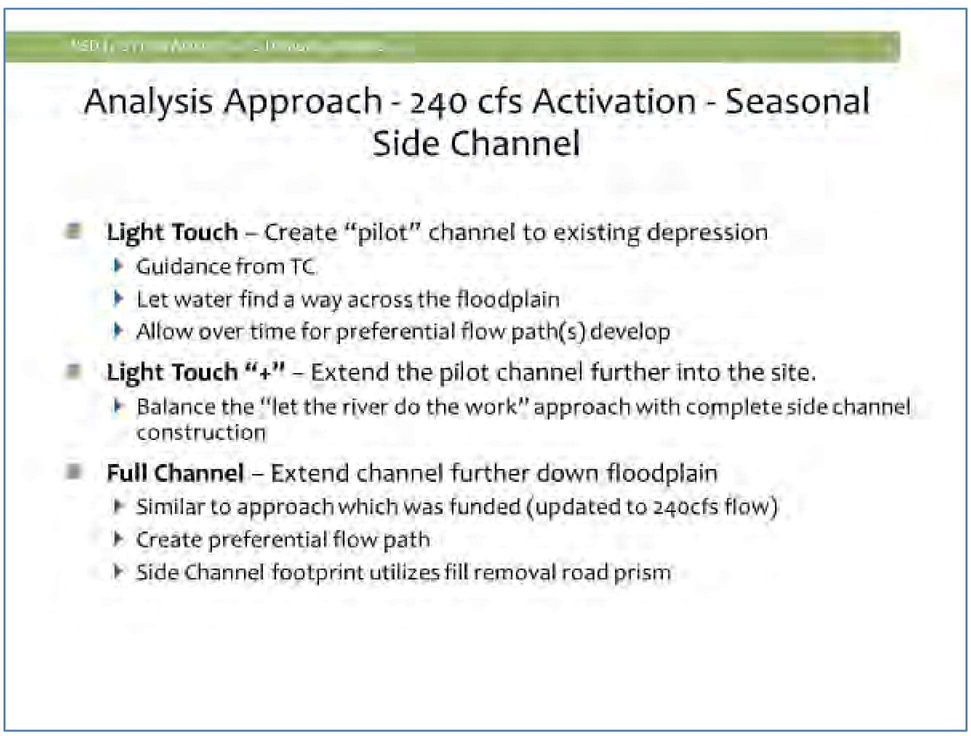
NSD | COTTONWOOD FLATS DESIGN GUIDANCE

Light Touch – Design Guidance





Project Goals/Guidance – Reminder….
Create a floodplain side channel. Increase resting and holding areas for juvenile spring Chinook and steelhead fry.
500cfs v 240cfs channel. Target 240 cfs flow activation to increase flow duration.
Remove floodplain fill/gravel road prism (1998). Restore wetland habitat, promote floodplain heterogeneity, and restore natural riverine processes.
Strategically place large wood structures. Increase floodplain connection, encourage lateral channel migration, and add in-stream roughness, complexity, and cover.
Remove concrete bridge abutments and complete bank restoration on left bank.
Balance construction impacts and costs with overall project benefits.



Analysis Approach - 240 cfs Activation - Seasonal Side Channel
Light Touch – Create "pilot" channel to existing depression
Guidance from TC
Let water find a way across the floodplain
Allow over time for preferential flow path(s) develop
Light Touch "+" – Extend the pilot channel further into the site.
Balance the "let the river do the work" approach with complete side channel construction
Full Channel – Extend channel further down floodplain
Similar to approach which was funded (updated to 240cfs flow)
Create preferential flow path
Side Channel footprint utilizes fill removal road prism

NSD | COTTONWOOD FLATS DESIGN GUIDANCE

Analysis Approach

- Create composite WSE/GWSE "surface"
  - Develop stage-discharge relationship for several points within the project reach using hydraulic model output and groundwater data.
  - Create composite surface for a given flow
    - Repeat over range of flows of interest
  - **Not perfect**, but illustrates some issues worth discussing
    - Static condition – doesn't reflect true "proposed" conditions

Date: September 26, 2019

From: John Ferguson, HCP Policy Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the July 9, 2019 HCP Policy Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Policy Committees met at the Chelan PUD office in Wenatchee, Washington, on Tuesday, July 9, 2019, from 9:00 a.m. to 12:40 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Steve Parker (Yakama Nation [YN] HCP Policy Committees Representative) and Cody Desautel (Colville Confederated Tribes [CCT] Natural Resources Director) will discuss with their respective policy staff about convening the YN and CCT Tribal Councils to discuss potential paths forward for the Scaffold Camp Acquisition #2 Project, including third-party ownership (Item V-A).
- Tracy Hillman (HCP Tributary and Hatchery Committees Chairman) will communicate HCP Policy Committees guidance to the HCP Tributary and Hatchery Committees to base funding decisions on technical merit, and to notify respective HCP Coordinating and Policy Committees representatives of any potential policy issues needing to be addressed in those forums (Item V-A). *(Note: Hillman communicated this guidance to the HCP Tributary and Hatchery Committees, as discussed.)*
- Steve Parker and Cody Desautel will discuss with their respective policy staff about convening the YN and CCT Tribal Councils to: 1) attend a joint meeting and presentation by Chelan PUD, Douglas PUD, and YN and CCT HCP technical representatives about the function of the HCPs; and 2) provide guidance on land ownership issues that might impact implementation of the HCPs (Item V-A).
- HCP Policy Committees representatives will each discuss with their respective HCP Tributary and Hatchery Committees representatives the option of abstaining in lieu of a disapproval vote to preserve a policy position (Item V-A).
- John Ferguson (HCP Policy and Coordinating Committees Chairman) will coordinate with each HCP signatory about an optimal date, time, and location for an annual meeting of the HCP Policy Committees (Item VI-A).

Decision Summary

- There were no HCP Policy Committees Decision Items approved during today's meeting.

Agreements

- There were no HCP Policy Committees Agreements discussed during today's meeting.

Review Items

- There are no HCP Policy Committees items that are currently available for review.

Finalized Documents

- There are no HCP Policy Committees documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Policy Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. Kirk Truscott (CCT HCP Coordinating Committees Representative) said Cody Desautel will be 30 minutes late and requested that the YN agenda item be postponed until Desautel arrives. No other changes were requested.

B. Purpose and Objectives (John Ferguson)

John Ferguson summarized the three objectives for this meeting are to: 1) have a clear exchange of thoughts, opinions, and position on this issue; 2) develop guidance for the HCP Tributary and Hatchery Committees; and 3) maintain the proper functioning and implementation of the HCPs.

Ferguson said as history shows, implementation of the HCPs is going extremely well. He recalled in 2013, the first official check-in was very positive. He said the HCP Coordinating Committees have worked through all issues, fish passage goals have been met, and spill is in compliance. He said the HCP Hatchery Committees have been successful in meeting the hatchery production and mitigation goals, and the HCP Tributary Committees have funded many projects and have now built up the fund accounts to be able to implement large-scale projects. He said the issue at hand is just one small sliver in a hugely successful program.

II. HCP Tributary Committees

A. Review of Events and Revisions to Decision Evaluation Criteria (Tracy Hillman)

Tracy Hillman said a document titled, "Dispute Regarding Basis for Decision Making in the HCP Tributary Committees," (information package; Attachment B) was prepared by the HCP Tributary Committees in response to a formal dispute submitted by the YN, dated May 23, 2019. Hillman clarified that the YN has since withdrawn the formal dispute; however, the information package, as distributed to the HCP Policy and Coordinating Committees on June 11, 2019, refers to the issue as a dispute, which is not the case at this time. Hillman said the information package reviews the sequence of events concerning this issue including two parallel paths: 1) development of scoring criteria for funding projects; and 2) review and voting on a draft Statement of Agreement (SOA).

Hillman said the HCP Tributary Committees have always followed criteria outlined in the "HCP Tributary Committees Policies and Procedures for Funding Projects," (Policies and Procedures document) when making funding decisions. He said the criteria consider the biological benefit, technical merit, durability, feasibility, and cost effectiveness of a proposed project. He said in 2018, Brandon Rogers (YN) and Catherine Willard (Chelan PUD) became new representatives on the HCP Tributary Committees. Hillman said both Rogers and Willard have experience working on the Upper Columbia Regional Technical Team where there are very specific scoring criteria for evaluating projects. Hillman recalled that Willard asked about detailed evaluation criteria in the Policies and Procedures document, and at the time there were only general criteria. Hillman said Willard expressed interest in developing specific criteria and Rogers agreed. Hillman said as suggested, the HCP Tributary Committees started the process of developing specific scoring criteria to include in an updated Policies and Procedures document.

Hillman said the other path began in December 2018, when the HCP Tributary Committees received a General Salmon Habitat Program Proposal from the YN titled, "Scaffold Camp Acquisition #2 Project." Hillman said the HCP Tributary Committees evaluated the project and based on the general criteria in the Policies and Procedures document, agreed this is an important property to protect and a good opportunity to restore a side-channel. Hillman said Chris Fisher (CCT HCP Tributary Committees Representative) agreed with the biological importance of the project; however, he received policy-level direction to vote "no" because approving the project meant the YN would own property in the Methow River Basin. Hillman clarified a "no" vote from the CCT had nothing to do with the HCP Tributary Committees evaluation criteria; rather, it was a policy-level directive that overrode the Committees criteria. He said at that time, the HCP Tributary Committees brainstormed what could be done to protect this property and recommended that the YN discuss the acquisition of the parcel with other conservation-minded entities such as the Methow Salmon Recovery Foundation, Methow Conservancy, Washington Department of Fish and Wildlife (WDFW), or the CCT, and coordinate enhancement work on the property with the YN. Hillman said the YN was not supportive of this recommendation and indicated they would likely dispute the decision based on principle. He said after internal deliberation, the YN elected not to dispute the decision on the Scaffold Camp Acquisition #2 Project but decided to develop an SOA that places boundaries on how the HCP Tributary Committees make funding decisions. He said on February 25, 2019, the YN distributed a draft SOA titled, "Basis for Decision Making in HCP Tributary Committees," which stated that the HCP Tributary Committees will make mitigation funding decisions based exclusively on the merits of proposed projects (biological benefit, technical merit, feasibility, durability, and cost effectiveness) having a direct nexus to plan species, plan species habitat, or plan species management. Hillman said the draft SOA was available for a 45-day review. He said no edits to the draft SOA were received and during the HCP Tributary Committees meeting on April 11, 2019, he asked each HCP Tributary Committees representative to vote on the SOA as well as provide justification for their vote. He said all representatives voted "no" except for the YN. He said the reasons for voting "no" on the draft SOA included: 1) the representatives believe the evaluation criteria in the Policies and Procedures document are sufficient for evaluating project proposals; 2) the representatives believe this is more of a tribal issue and not an HCP issue; and 3) representatives do not want to lose their discretionary rights to vote "no" on a project for reasons that may not entirely fit within the Policies and Procedures criteria.

Hillman said while the SOA was under review, the HCP Tributary Committees were also reviewing and updating their criteria for evaluating restoration, protection, design, and assessment projects. He said specific criteria for biological benefit, technical merit, durability, feasibility, and cost effectiveness were developed for each project type. He said this is when the two parallel paths converged. He said there were now more robust and specific criteria to evaluate projects and the HCP Tributary Committees decided an SOA was not needed to stipulate the use of these criteria. He said because the draft SOA was rejected, the YN elected to submit a formal dispute in accordance with Section 11 of the HCPs, which was the impetus for developing the information package (Attachment B). He said since announcing the formal dispute, the YN has withdrawn the dispute and the HCP Policy Committees are convened today to further discuss this topic.

Hillman said he appreciates that this is no longer a formal dispute. He said when an HCP Tributary Committees representative votes "no" on a proposed project, as Chair of the Committees he must understand the reasonings for the "no" vote because he has to communicate the decision and the reason for the decision to the project sponsor. He said the sponsor then has an opportunity to address the issues and resubmit an application, which they often do. Hillman said a "no" vote is often due to the project sponsor proposing the wrong project, in the wrong place, at the wrong time, any combination of these factors, or the cost effectiveness of the project. He said, however, Fisher supported the project based on the benefits to the resource but was directed by policy staff to vote "no." Hillman argued that the HCP Tributary Committees Policies and Procedures are not the issue; rather, the issue is policy-level decisions that override HCP Tributary Committee criteria. He said the HCP Tributary Committees have criteria in place; however, policy staff can override these criteria. He said if this topic was still a formal dispute that went to the HCP Coordinating Committees, he believes the vote at the HCP Coordinating Committees level would be similar. He asked then, do the HCP Coordinating Committees also have an issue with their criteria for making decisions? He said the HCP Coordinating Committees also receive direction from policy staff. He said, therefore, this discussion within the HCP Policy Committees is valuable because this group oftentimes is providing guidance to the technical representatives. He said he is in the position where he needs to defend the HCP Tributary Committees position with project sponsors. He said he needs to understand and believe the decisions are correct, and this Scaffold Camp Acquisition #2 Project is the first case where he could not defend the decision based on what was best for the resource. He said the HCP Tributary Committees decision was trumped by policy staff, which is not the fault of the HCP Tributary Committees and is why he believes the HCP Policy Committees need to address this issue.

John Ferguson asked to what extent is ownership captured in the HCP Tributary Committees criteria. Hillman said ownership only applies to protection projects where the land is typically owned by the project sponsor. He said when a protection project is evaluated, the HCP Tributary Committees consider who will hold the title. He said, for example, if the entity has a bad reputation for allowing disturbances to occur, the HCP Tributary Committees would vote "no" based on biological merit and durability and would indicate they do not believe the entity would adequately protect the resource. He said the criteria do not indicate who can or cannot own a property, but the criteria do question whether the landowner is appropriate. He said, for example, anytime a Plan Species Account is used to fund projects, the landowner must allow public access and maintain the resources. Jim Craig asked, so the criteria do give the HCP Tributary Committees the ability to say who owns the property? Hillman said yes, the HCP Tributary Committees could say they believe that a property should be protected but that a certain entity should not hold title and recommend that another entity hold the title. He said similar language is included in the HCPs.

Alene Underwood (Chelan PUD HCP Policy Committees Representative) clarified that per Section 7.4.4 of the Rock Island and Rocky Reach HCPs,[1] "Title may be held by the District, by a resource agency or tribe or by a land or water conservancy group, as determined by the Tributary Committee." Tom Kahler (Douglas PUD HCP Coordinating and Tributary Committees Representative and HCP Hatchery Committees Alternate) said, importantly, there are separate sections in the HCPs describing ownership of assets and funding decisions, which are distinct from each other. Kirk Truscott said Section 7.4.4 of the Rock Island and Rocky Reach HCPs[2] also states, "Unless the Tributary Committee

[1] Also, per Section 7.3.7.4 of the Wells HCP.
[2] Also, per Section 7.3.7.4 of the Wells HCP.

determines that there is a compelling reason for ownership by another entity, the District shall have the right to hold title." Truscott said it may not be who is the best entity to hold the title; rather, it is more a function of multiple entities are capable of holding titles.

Jim Brown (WDFW HCP Policy Committees Representative) asked if the HCPs include reserved rights, and Kahler said there are sections describing authorities to whom each of the signatories are subject. Kahler said the HCPs were not intended to take away rights granted in other documents; rather, the HCPs are a recovery plan. Brown said it seems then by signing the HCPs, the signatories agreed to comply with the processes and criteria contained within the HCPs. Kahler explained that the HCPs define each committee and state that it is up to each committee to develop its own operating procedures and submit them to the HCP Coordinating Committees. He said ultimately, the HCP Coordinating Committees deferred management of the respective operating procedures to each committee so long as the procedures uphold the tenants of the HCPs and accomplish the objectives outlined in the HCPs. Ferguson also noted that Section 9.7 of the Wells HCP[3] states "However, the Party shall use reasonable efforts to exercise their rights and authority under such statutes, regulations, and treaties (consistent with their duties and responsibilities under those statutes, regulations and treaties) in a manner that allows this Agreement to be fulfilled."

Hillman said the HCP Tributary Committees review their Policies and Procedures document every year and evaluate whether the document needs revising. He said, for example, conservation easements formerly did not require public access, but the HCP Tributary Committees changed this to allow public access.

Ferguson said the HCP Coordinating Committees discussed this potential dispute in December 2018, after it was first discussed within the HCP Tributary Committees. He said there was general agreement that this issue could not be resolved within the HCP Coordinating Committees and would need to be elevated to the HCP Policy Committees. He said this general thought did not change when the topic was discussed again in January and February 2019. He said there was never a vote, but this was the way the discussion was headed, which is what led him to contact the YN to convene the HCP Policy Committees for further discussion of this issue outside the formal dispute process.

Brown said he believes caution needs to be taken about overly focusing on the HCP Tributary Committees policies and procedures and to keep the focus of the discussion at the policy level. He suggested focusing on how to make policy decisions that translate into marching orders to technical staff.

Ritchie Graves (National Marine Fisheries Service [NMFS] HCP Policy Committees Representative) said he is interested in the unbiased implementation of the HCPs and believes it is worth refreshing

---

[3] Also, per Section 9.4 of the Rock Island and Rocky Reach HCPs.

representatives' memories on how the HCPs got to where they are today. He recalled back in the 1980s, there was a lot of litigation, fisheries managers were operating under court orders, there was a very prescribed but miniscule amount of spill for fish passage, and everything was tied strictly to monetary value. He said in the mid-1990s, after the Snake River stocks started to be listed and stocks in the Upper Columbia River Basin were not in good shape, these statuses were reviewed. He said it is his understanding that the U.S. Fish and Wildlife Service was very pro-HCP and convinced Will Stelle (NMFS Regional Administrator) there should be an effort devoted towards developing HCPs for the Mid-Columbia PUDs. Graves said he was part of the third team for NMFS to participate in this process, which took 8 to 10 years to finish. He said in 2001, he participated in the final effort to complete the process. He said key improvements in the final effort included a better understanding of the Tributary Program portion of the HCPs and the addition of the decision matrix the HCP Coordinating Committees use to make sure survival standards[4] are being met and determine how to continue to achieve those performance standards. He said there were also clarifications concerning the Hatchery Program portion of the HCPs. He said in August 2003, forward progress of the HCPs slowed when NMFS was issuing permits for Grant, Chelan, and Douglas PUDs. He said it was at this time that Grant PUD elected to leave the HCP development process. He said by the end of 2003 when the Biological Opinions (BiOps) were submitted to the Federal Energy Regulatory Commission (FERC), there were still some disputes; several parties were not enamored with the HCPs and even submitted filings to FERC expressing disapproval of components of the HCPs. He said ultimately, FERC approved the interim BiOps and NMFS issued a second round of BiOps.

Graves said there is a lot of history here and a lot of effort went into getting the HCPs to where they are today. He said following FERC's approvals he believes the Columbia River Inter-Tribal Fish Commission and the YN was in the process of formally disputing the FERC approvals. He said after a tribal meeting, the YN ultimately decided it would be more beneficial to join the HCPs rather than challenge them. Graves said some environmental groups had the option to join but declined, he believes due to staffing reasons. He agreed with Ferguson that implementation of the HCPs to date has gone well. He said he believes the framers of the HCPs did a good job in laying out the key issues, and he views the issue today as a bit outside of what anyone was entertaining would be an issue at the time the HCPs were negotiated—where there are policy goals over-riding technical goals and how to address this. He said he also agrees with Ferguson's and Hillman's appreciation for the HCP Policy Committees convening to address this issue because he does not want to see technical staff tearing each other up over this when it is really out of their control. He said this type of thing hurts working relationships and he believes the HCP Policy Committees owe the technical committees some guidance on this issue. He said he is still trying to understand if there is an issue with this particular

[4] Figure 1. in Section 4.1.2 of the Wells HCP (and, as included in the RI and RR HCPs).

project other than ownership. He said he understands the tribes have relationships, some good some bad, and the job of the HCP Policy Committees is to uphold the viability of the HCP process. He asked how to steer this process so it cannot be accused of being prejudice on behalf of one tribe or another. He said decisions need to be made to make sure this process is fair and objective. He said to this day, he does not know of any HCPs for a hydropower project in the country and he believes the Mid-Columbia HCPs are working well. He said the signatories have really focused on benefiting the species. He said he personally has a lot of pride in how the HCPs have functioned over time and he hopes to see them continue to function in the future.

Steve Parker explained the reason why the YN initially did not want to sign the HCPs was based on concern about the voting procedures being consensus-based, and the perceived conveyance of rights and authorities to the HCPs, which they did not possess. He said the YN has worked very hard to establish themselves as a self-regulating fisheries manager and the Tribal Council takes this very seriously. He said the YN is reluctant to share authorities with other entities that do not share the same views for the resources; however, at that time, it was decided it was better to be in the room where the HCP decisions are being made rather than dealing with the outcomes, and so the YN signed onto the HCPs.

III. Yakama Nation

A. Basis for Decision Making in the HCP Tributary Committees (Steve Parker)

Steve Parker thanked the HCP Policy Committees for convening today. He said this is not a typical issue and his key objectives today are to make sure the HCP Policy Committees understand what the YN perceptions are and the reasoning behind this issue. He said it is equally important to determine what remedies may exist. He said this is a difficult situation to deal with at this level. He said he wants to separate the specific example that precipitated this meeting from the principle the YN is trying to bring to the HCP Policy Committees for awareness and guidance, which is to define the acceptable criteria for voting procedures.

Parker said stepping back several months, the YN was taken by surprise by the decision on the Scaffold Camp Acquisition #2 Project. He clarified the CCT position was no surprise to the YN, as both tribes have historically been very candid about circumstances of geographic regions in the Upper Columbia River Basin. He said the YN has an appreciation for the CCT position and understands it. He said the YN's greater concern was not about the specific detail of this vote but rather about the larger principle of what criteria can be brought into a vote. He questioned where there should be bounds around what is considered acceptable criteria. He recalled when the HCPs were developed, the Parties agreed there would likely be 9% unavoidable project mortality even with all measures to improve passage survival. He said of this 9% only about 7% could be mitigated through hatchery production, which he believes was based on limitations in hatchery capacity. He said the other 2% was to be mitigated through habitat improvements. He said then as now, there was no way to document whether the 2% was being achieved; however, it was taken in good faith that by implementing the Tributary Habitat Program this would satisfy this portion of the mitigation program. He said based on this agreed upon level of mitigation required, implementation plans and procedures were developed and incorporated into the FERC licenses to operate the respective projects. He said the YN's concern is about the new criteria developed and incorporated into the HCP Tributary Committees Policies and Procedures document, which in the YN's view presents a material modification to the FERC license terms. He said the YN is conducting an internal analysis of this; however, they have not yet come to a final determination. He said the analysis is looking into the possibility of having FERC weigh in on a dispute; however, it appears this might not be possible. He said it is not clear to him after reading the HCPs what happens after an HCP Policy Committees decision. He said the HCPs just state other remedies are available. He said the YN is in a quandary being the Party bringing this dispute. He said if the dispute cannot be resolved within the HCP Policy Committees, what happens next? He said he hoped to discuss this with the HCP Policy Committees to search for solutions.

Parker said the YN is struggling with the potential that Parties can bring criteria to a funding decision that do not relate to benefiting the resource. He said this establishes a precedent that the YN does not want to contemplate. He said each Party potentially has differences in policy perspectives and management priorities. He said if these differences can drive the decision-making, he views this as a degradation in the process of the mitigation program and what the signatories signed up for.

IV. Discussion

A. Comments and Perspectives (All)

Ritchie Graves said one of his concerns is starting a dynamic within the committees whereby anyone who feels slighted will elevate a topic to the policy level. John Ferguson said he believes all HCP Policy Committees representatives share this concern, which gets to the heart of his third objective of today's meeting, which is to maintain the proper implementation of the HCPs.

Tom Kahler asked Steve Parker to clarify what he said about changes to the FERC license. Parker explained that his hypothesis is that to the extent the HCP Tributary Committees policies and procedures are part of the FERC license terms, by incorporation (i.e., the HCP and all its derivative parts, including its operating procedures, are considered part of the license), any change to those voting criteria represent a change to the license terms. Ferguson said the HCP Tributary Committees Policies and Procedures document is not part of the HCP text; rather, the HCP states that the HCP Tributary Committees will develop these criteria. Parker said it is a negotiated process. He said thinking back to when the HCPs were negotiated, if someone had suggested a decision criterion based on policy goals other than mitigation priorities, this would be hard to agree to (i.e., decision criteria based on territorial claims or political aspirations would not have been acceptable then and, accordingly, should not be acceptable now). He said this is adding an element that has nothing to do with mitigation itself.

Kahler said early on, there were a lot of questions about how the implementation of the tributary program would work. He said it started with an agreement to coordinate the selection of habitat projects for funding with the ongoing annual project-funding cycle of the Washington State Salmon Recovery Funding Board (SRFB) and adapted to accommodate other regional funding needs over time. He recalled Bob Rose (YN HCP Tributary Committees Representative, retired) wanted the HCP Tributary Committees to be self-directed in project development and funding, and now the committees have finally achieved this, while maintaining their integration with the SRFB annual funding cycle. Kahler said the approach to implementing the tributary program has always been an adaptive process tailored to what the HCP Tributary Committees view as being needed, and the committees have adapted their policies and procedures accordingly. He said the HCP Tributary Committees are unique in that all representatives are truly only interested in benefiting the resource. He said the HCP Tributary Committees are not flawless, but there has never been an atmosphere of partisanship. He said he believes the HCP Tributary Committees have done a lot of good things and now the committees have encountered a new issue. He said he believes it is important that the HCP Policy Committees provide direction to the HCP Tributary Committees regarding Section 7.3.7.4 of the Wells HCP[5] (Ownership of Assets).

Ferguson said he is not sure that tying the five general criteria outlined in the HCP Tributary Committees Policies and Procedures document to the FERC requirement is accurate. He said the HCP is what is in the FERC license, and the HCP states "The Tributary Committee shall select projects and approve project budgets from the Plan Species Account by joint written request of all members of the Tributary Committee." Ferguson said he is unsure whether there is a nexus between the five general criteria and FERC license because the HCP Tributary Committees Policies and Procedures document is not part of the actual HCP text. Alene Underwood said however, each year the PUDs submit an annual report to FERC for approval, which outlines the activities conducted that year for all HCP committees. She said FERC approves the annual reports, and therefore, the changes noted within.

Cody Desautel said he does not recall this being an issue prior to 3 years ago, and he believes the concern started when the YN opened the coho salmon fishery in the Methow River basin. He said historically, the CCT have been supportive of habitat work; however, the incident with the fishery

[5] Also, per Section 7.4.4 of the Rock Island and Rocky Reach HCPs.

threw up a red flag for the CCT Council who now thinks the YN uses habitat work to leverage work on certain lands. He said this is why the CCT Council is opposed to land purchases by the YN in the CCT territory. He said the question is how to move forward from here. He recalled some discussion about third-party ownership where there is still benefit to the resource but that avoids territory issues. He suggested developing alternatives that need to be presented to, and approved, by the respective tribal officials. He said he and Phil Rigdon (YN Natural Resources Manager) both want to see habitat work done, and this situation is difficult for everyone. Jim Brown asked Desautel if he and Rigdon have discussed this issue. Desautel said yes, and they discussed attempting to convene the YN and CCT Tribal Councils because ultimately those are the people who have the concerns. Desautel said this meeting would also need someone with an HCP background to help find a workable solution. Ferguson agreed with Desautel and said the principle issue is outside the HCPs. Ferguson said the HCP Policy Committees can try and provide guidance to the HCP Tributary Committees; however, this would only be a work-around and not a solution. He said the solution needs to fit within the respective Tribal Councils' guidance.

Parker said the YN has discovered that in the course of implementing the Columbia River Accord Habitat Program in the Upper Columbia River Basin, it is in the best interest for the YN to own the property where work is being done because there can be constraints with working with a property owner. Parker said constraints may take the form of differences in opinion on project objectives, design and implementation, or the terms of a conservation easement on the property after restoration work is completed. He said he does not believe the YN is interested in owning a lot of land because this comes with liabilities and responsibility, and he does not believe it is the best use of the YN restoration funding to buy and hold property. Desautel agreed with Parker noting that property owners with little technical background can get very opinionated about what needs to be done. He said, however, from the CCT Tribal Council's view, the CCT would prefer to own the land if it is located within the CCT territory. He asked about the possibility of WDFW being a third-party owner. Ferguson agreed this might be a solution and suggested perhaps identifying the geographic region where the tribes agree third-party ownership is required to address future similar issues.

Brown said he was directly involved with the YN coho salmon fishery incident. He clarified it was an unfortunate case of a lower-level staff person establishing a regulation that was not fully vetted with policy staff and the regulation was withdrawn shortly after it was released. Parker agreed it was an oversight, which caused a bit of friction between the tribes. Desautel suggested if the YN and CCT Tribal Councils convene, this should be explained and clarified. Parker agreed and said the YN action did not consider the CCT's likely reaction.

Kirk Truscott said he believes this issue can only be resolved at the Tribal Council level. He said what is needed is solution-oriented direction from the Tribal Councils, whether it be identifying a geographic area or other options for what can be done in these situations. He said it is too cumbersome to take every solitary issue to a council, on a case-by-case basis. He said this puts staff in a difficult position and may result in lost opportunities due to the time involved to seek council approvals. He said further, he believes the HCP Tributary Committees should continue evaluating projects based on technical merit and this should be set apart from policy decisions.

Graves recalled several regulating documents and discussions behind the language in the HCPs regarding decision making by unanimous consent, and he said the focus at that time was keeping the committees from misusing funds on poor projects. He said he thinks the Parties were reviewing all the FERC orders and everybody took comfort in the idea that if something was bad for a habitat project, the Parties would have the ability to veto the decision. He said, however, the Parties did not account for good projects that could be funded, but which would not be funded for policy reasons. He said this was a bit of a blind spot in the HCPs. He agreed convening the Tribal Councils seems to be a positive step because he is unsure the HCP Policy Committees have any more ability to resolve this issue than the technical staff in the other committees. He said regarding the YN going to FERC for resolution, he said he believes it will be difficult to get FERC to weigh in on tribal issues; rather, he believes convening the Tribal Councils is the better option. He asked what the HCP Policy Committees can do to help move this forward.

Desautel said he can contact Rigdon to start these discussions of trying to convene the Tribal Councils. Parker agreed this is worth doing to resolve this specific issue; however, he noted there is still the broader principle to remain focused on. He said regarding Graves's comment about contacting FERC, the YN believes the substance of the principle has merit but questions the procedural hurdles in place to access FERC. He said the substantive issue in his mind is to what extent can other factors besides fish and wildlife restoration be a basis for decision-making. He said FERC may not want to get involved in a tribal dispute; however, the YN does not view the larger principle as a tribal dispute. Graves said he understands the broader principle and agrees it is a fair question to ask.

Brown said he has participated on a workgroup that had a consensus-driven model where parties departed from the workgroup because consensus could not be reached on particular issues. He said when there are ideological or policy opinions that underpin a decision it can wreak havoc on a consensus-driven process. He asked where is the line, what is on or off the table?

Jim Craig said for the Scaffold Camp Acquisition #2 Project, it seems the HCP Tributary Committees diverged from the established Policies and Procedures document and did not vote based on technical merit. He said this is a unique situation given that all HCP Tributary Committees representatives were initially supportive of the project before policy-level aspects to the proposed project intervened. He said to date, the HCP Tributary Committees have functioned very well and he hopes this continues in the future. He said Section 7.3.7.4 of the Wells HCP and Sections 7.4.4 in the Rock Island and Rocky Reach HCPs discuss ownership of assets and indicate the HCP Tributary Committees may make ownership determinations of real and personal property purchased with funds from the Plan Species Account. He said the sections state that title may be held by a PUD, resource agency, tribe, or a land or water conservation group. He said it seems in this case, where the title holder is the issue, the YN and the CCT should be exploring options for a third-party to hold the title. He said this could be a PUD, WDFW, or a conservation group such as the Salmon Recovery Foundation or the Methow Conservancy, both of which have proven track records of outstanding land conservation and habitat recovery implementation.

Underwood said in her experience on the HCP Hatchery Committees, staff have worked very hard to accommodate work-arounds and she believes the HCP Tributary Committees do the same. She applauded these committees for this; however, she asked how long can staff be asked to do this? She said she advocates on behalf of the HCPs and the fantastic track record so far, and she hopes for more transparent, repeatable criteria to evaluate projects. She said she does not believe this can be achieved on this level; rather, it needs to be addressed at the highest level to continue the good work. She said continuing to have staff do work-arounds is not a long-term solution. She said it would be a real shame if after so many years of demonstrated successes in all committees, this one thing puts a blight on the successful implementation of the HCPs, and how decisions have historically been made. She said the fact that all signatories can sit down in this room together is a testament to how well this process has worked. She said it is important to pass on these sentiments and information to the Tribal Councils. She said Chelan PUD is willing to do whatever they can to help.

Tracy Hillman said a lot of what is being discussed today has also been discussed within the HCP Tributary Committees. He agreed with Parker about the benefits of owning the property where habitat restoration work is being conducted, not only for implementing actions but also for ongoing monitoring. He said determining what is in and what is out is a difficult question. He recalled reviewing the YN's draft SOA and asking the HCP Tributary Committees about other issues that might fall outside the established criteria, and the committees could not think of any. He said after this discussion, the HCP Tributary Committees were reviewing a protection project on Nason Creek that would be a great property to protect; however, a voting member received input that if agreement cannot be reached with the project sponsor on another project, that entity would not approve the Nason Creek project. He said there is no issue with the HCP Tributary Committees general and specific evaluation criteria; rather, the issue is with policy-level input that overrides the HCP Tributary Committees criteria. He said this could happen in any HCP Committee. He agreed with Parker that this is about the principle of decision-making. He said HCP Tributary Committees representatives could not agree on the YN's draft SOA because in part it did not allow policy-level authority. Brown said further, sometimes technical staff are not aware of the reasoning behind policy decisions, which can lead to conflict.

Kahler said he has been an HCP Tributary Committee representative since March 2005. He recalled in the early years discussing similar issues of what and how to do things and when and where can policy intervene. He said this reminded him of the Enloe Dam removal project that never came through the HCP Tributary Committees because of a policy issue. From a biological-benefit level, removing the dam and opening the Similkameen habitat is perhaps the most profound action that could be taken for certain salmonid species. He said that, before submitting the proposal to the HCP Tributary Committees, project proponents asked the PUDs whether they could support this project. He said prior to Okanogan PUD's recent decision to not energize Enloe Dam, Douglas PUD was constrained because Douglas PUD has a basic operating principle to not interfere in the affairs of other PUDs. He said although he believes this is a great project, he could not have voted yes had it been brought to a vote prior to Okanogan PUD's decision to not energize. Therefore, the proponents never submitted a proposal for assisting with dam removal, knowing that the PUD could not approve it. He said another situation might be when an entity known to have done great harm in the grand scheme of resource management proposes a project with biological benefit, can the PUD support this? He said there was another project where design work was already being conducted, another entity proposed to do something there, and the project was rejected because someone else was already working there. He said a few projects have also been approved with relatively low biological benefit because of an expectation of realizing greater habitat benefits in the future with the relationships fostered by approval. These examples represent a few instances that did not cleanly fit within the evaluation criteria. Kahler said over time, there has been a pattern of approving good projects. He said there have also been projects that were not approved because the committees could not reach a consensus on benefits. He said overall, the evaluation criteria have served the committees well, and now include more specificity the HCP Tributary Committees representatives asked for. He said these policies and criteria act as a filter in how projects are evaluated. He said there is nothing wrong with these; rather, ownership of assets needs to be clarified by policy staff.

Parker said for this specific case, it seems seeking third-party ownership is the optimal route, which will need to be a council-level decision. He said for the larger principle, he believes technical staff should only be tasked to vote based on technical merit and if a policy issue arises this should be elevated to the next level. He said from the YN's point of view, the *US v. Oregon* process has been effective and can be viewed as a successful model. He said under *US v. Oregon* there are two technical committees (Production Advisory Committee and the Technical Advisory Committee) that must reach a consensus on the technical aspects of an issue so that the policy aspects can be elevated to the Policy Committee or argued in front of a judge. He said in the event of a dispute, the topic is not about the data; rather, it is a policy issue.

Hillman noted that the Scaffold Camp Acquisition #2 Project is a rare situation where a technical team made a technical decision but was given policy direction to not approve the project. He said he does not believe this is a conflict with the HCPs, it is just a single issue that needs to be addressed at the highest policy level.

Underwood said the HCPs specifically describe the role of the HCP Tributary Committees including their right to make decisions within the committees. She said she is hesitant to change this. She said, however, to Hillman's point, this is a rare situation.

V. Summary

A. Consensus on Recommendations (All)

The HCP Policy Committees discussed and summarized four key recommendations and associated action items based on comments and perspectives expressed, as follows:

<u>Recommendation #1: The YN and CCT Tribal Councils meet and discuss potential paths forward for the Scaffold Camp Acquisition #2 Project, including third-party ownership.</u>

John Ferguson asked if there is time sensitivity associated with this project. Tracy Hillman said he is unsure whether the landowner has sold the property yet, but if it is still available, the HCP Tributary Committees are interested in protecting it.

Ferguson recalled Tom Kahler providing a number of examples of past history where decisions were made based on factors outside of the formal criteria. Ferguson said this spoke to what is the principle solution here. He said it seems this can only be answered by the Tribal Councils. He asked if the HCP Policy Committees want to suggest defining acceptable land ownership in geographical terms, should they simply indicate this decision is outside the HCPs, or are there other recommendations? Cody Desautel said he believes that it is important to educate the Tribal Councils about the mitigation resources, the intent and background of the FERC license and HCPs, and provide a clear understanding of what the signatories are trying to do and why. He said he believes this will provide better context for funding decisions. Ferguson agreed and said it would also be good to clarify the coho fishery incident by explaining that history, too. Kirk Truscott cautioned that there is much more history between the YN and the CCT on fisheries and natural resource management activities than just the coho salmon fishery incident. He suggested staying focused on reaching agreement on a predetermined path forward on land acquisition. Steve Parker said he would like to reach a process that is not rights based; rather, it would be solely based on best mitigation for the resources.

Jim Brown said WDFW is interested in helping in any way possible and hopes to see continued successful implementation of the HCPs in the future. Ritchie Graves agreed and said the decision-making process needs to be monitored carefully and if this begins to happen regularly it will need to be revisited.

Kahler noted that more than 90% of project applications received are from entities who have no voice in the process. He said if an entity outside the HCP Tributary Committees brings in a project for funding and the project is rejected, there is no disagreement that can be disputed. He said as signatories to the HCPs bring forth projects for funding, this has placed the signatory at a different level of consideration compared to a non-signatory. He said the HCP Tributary Committees try to treat all projects the same, but project sponsors who are also a signatory to the HCPs have the right to dispute.

Ferguson said Parker and Desautel will discuss convening the YN and CCT Tribal Councils with their respective policy staffs and potential paths forward for the Scaffold Camp Acquisition #2 Project, including third-party ownership.

Recommendation #2: Provide HCP Policy Committees guidance to the HCP Tributary and Hatchery Committees regarding funding criteria.

John Ferguson said Tracy Hillman will communicate HCP Policy Committees guidance to the HCP Tributary and Hatchery Committees to base funding decisions on technical merit, and to notify respective HCP Coordinating and Policy Committees representatives of any potential policy issues needing to be addressed in those forums.

Recommendation #3: Request Guidance from the YN and CCT Tribal Councils on land ownership issues.

Kirk Truscott reiterated Cody Desautel's suggestion to first provide context about the HCPs before requesting guidance. Alene Underwood and Tom Kahler agreed.

John Ferguson said Steve Parker and Desautel will discuss with their respective policy staffs about convening the YN and CCT Tribal Councils to: 1) attend a joint meeting and presentation by Chelan PUD, Douglas PUD, and YN and CCT HCP technical representatives about the function of the HCPs; and 2) provide guidance on land ownership issues, which might impact implementation of the HCPs.

Recommendation #4: Consider abstention in lieu of disapproval to preserve respective policy positions.

Alene Underwood suggested considering using discretion in the form of abstention as opposed to a "no" vote. She said this approach preserves policy views but also maintains the HCPs. She said this has been discussed before within the HCP Hatchery Committees. She said understanding that abstention is not perfect, it seems it would occur rarely, and it give Parties the ability to state their policy position in a more transparent manner. She said this does not necessarily address the issues, but it preserves the functionality of the HCPs and the HCP committees.

Steve Parker agreed there is a lot of merit to this. John Ferguson said by abstaining the project still goes forward. Parker said, however, the Parties can still preserve their policy position. Underwood said, for example, there was a project within the HCP Tributary Committees from the Cascade Columbia Fisheries Enhancement Group for work at Tumwater Dam. She said after discussing this internally, Chelan PUD chose to abstain because the PUD thought approving or disapproving the project would be unfair to one party or another. She said abstaining preserved Chelan PUD's policy position while also recognizing the PUD signed onto something that needed to happen. Tom Kahler said for the Scaffold Camp Acquisition #2 Project, the intent of voting "no" was to keep the action from moving forward and abstaining would not do this. Kirk Truscott agreed abstention might work if the Party does not want to side with one position or the other; however, with the Scaffold Camp Acquisition #2 Project, abstaining would not work. Underwood said unless the direction from policy is that this outcome is acceptable. Jim Brown agreed with Underwood that this is something to consider in order to preserve the opportunity for the HCP Policy Committees to gather outside a formal dispute.

Brown said this also illustrates the need for the HCP Policy Committees to meet more frequently, to build a regular rapport within the committees and perhaps help with scheduling meetings. Underwood agreed it makes sense to gather under conditions other than just a dispute.
Tracy Hillman also agreed and said projects where there may be policy concerns will most likely happen with protection projects; and typically, if the HCP Tributary Committees are interested in using the Plan Species Accounts for protection it means the resource is in imminent danger of being lost and action needs to be taken as soon as possible. Ferguson agreed and said if the HCP Policy Committees met more frequently in person, the committees could convene by conference call on short notice if needed to address a time-sensitive issue.

HCP Policy Committees representatives will each discuss with their respective HCP Tributary and Hatchery Committees representatives the option of abstaining in lieu of a disapproval vote to preserve a policy position.

B. Final Remarks (All)

The HCP Policy Committees representatives thanked each other for the productive discussions during today's meeting.

VI. HCP Administration

A. Next Steps (John Ferguson)

John Ferguson will coordinate with each HCP signatory about an optimal date, time, and location for an annual meeting of the HCP Policy Committees.

MISSION: To fund and support sustainable, long-term, cost-effective projects that protect and restore Plan Species habitats and to foster partnerships with those that implement such projects.

Dispute Regarding Basis for Decision Making in the HCP Tributary Committees

June 10, 2019

Report from the Tributary Committees Chair

Wells, Rocky Reach, and Rock Island
Habitat Conservation Plans

TABLE OF CONTENTS

1 Introduction

The Yakama Nation has initiated the dispute resolution process as defined in Section 11 of the Anadromous Fish Agreement and Habitat Conservation Plans.[1] The dispute centers around the HCP Tributary Committees (HCP TCs) rejection of the Statement of Agreement (SOA) proffered by the Yakama Nation titled, *Basis for Decision Making in HCP Tributary Committees*. To be clear, the Yakama Nation is not disputing the HCP TCs decision to not fund the Scaffold Camp #2 Acquisition Project. This dispute is only about the HCP TCs rejection of the SOA. That said, I will provide some background beginning with the Scaffold Camp #2 Project, because the HCP TCs response to that project sets the stage for the disputed issue.

In December 2018, the HCP TCs evaluated an application from the Yakama Nation titled, *Scaffold Camp Acquisition #2 Project.* During the December meeting, all members except the Colville Confederated Tribes (CCT) supported the project. Even though all members (including the CCT) acknowledged the benefits of the project and believed the proposed property should be protected, the CCT representative was directed by the CCT Natural Resources Committee to vote "no" because the CCT Natural Resources Committee does not want the Yakama Nation owning land in the Upper Columbia (Wenatchee, Entiat, Methow, or Okanogan sub-basins).[2] Based on this outcome, during the December meeting, the Yakama Nation indicated they would dispute the HCP TCs decision. During the December meeting, the HCP TCs suggested ways to avoid a dispute (e.g., finding a different conservation-minded entity to own the land). Those suggestions were dismissed.

The Yakama Nation elected to not dispute the decision by the HCP TCs on the Scaffold Camp Acquisition #2 Project. Rather, in February 2019, the Yakama Nation offered a draft SOA titled, *Basis for Decision Making in HCP Tributary Committees,* which addresses the process and criteria by which the HCP TCs make funding decisions. The purpose of the SOA was to make sure all funding decisions made by the HCP TCs are based <u>only</u> on the merits of the project (biological benefit, technical merit, durability, feasibility, and cost effectiveness).[3] Any criteria having no direct nexus to Plan species, their habitat, or their management cannot be considered when evaluating proposed projects.[4] The SOA also noted that any signatory attempting to vote on the basis of criteria other than those directly related to resource impacts may abstain from voting. The Yakama Nation asked the HCP TCs to consider the draft SOA, make revisions/edits as necessary, and be prepared to vote on the SOA during the April meeting.

Because HCP TCs members provided no edits or revisions to the draft SOA, during the April meeting, I asked each member to vote on the SOA and provide justification for their vote. All members except the Yakama Nation voted "no" on the SOA. In general, most members voted "no" because they believed the SOA was not necessary (details of the reasons are found in the April meeting notes). The CCT said they

---

[1] The dispute resolution process is described in Section 11 of all three (Rock Island, Rocky Reach, and Wells) Hydroelectric Project Anadromous Fish Agreement and Habitat Conservation Plans.

[2] During TCs meetings, the CCT also referred to the Upper Columbia as "CCT Territory."

[3] As noted in the Yakama Nation Issue Statement, these evaluation criteria are not new. Although they were not defined explicitly, they were included in the earliest draft of the HCP TCs Policies and Procedures for Funding Projects. As long as I have been with the HCP TCs, they have used these criteria to make funding decisions. The one exception was the Scaffold Camp #2 Acquisition Project; but even then, all members (including CCT) acknowledged the biological benefit associated with the project. For the CCT, the issue was land ownership.

[4] Importantly, the draft SOA goes beyond the issue between the CCT and the Yakama Nation. The SOA targets the fundamental basis by which the HCP TCs make funding decisions.

could not support any SOA that removes their right to not approve HCP TCs funding to the Yakama Nation to purchase property in the Upper Columbia.

During the process of evaluating the draft SOA, HCP TCs also reviewed and updated their project evaluation criteria. Although the Policies and Procedures for Funding Projects included general criteria (i.e., biological benefit, technical merit, durability, feasibility, and cost effectiveness), there were no specific definitions or evaluation metrics associated with the general criteria. During March and April 2019, the HCP TCs identified and approved specific criteria for each general criterion for restoration, protection, design, and assessment projects. It was in part because of these approved evaluation criteria that several members indicated that an SOA was unnecessary. The HCP TCs did not exclude other criteria from being included in the evaluation of projects. However, they included the following language:

> *During review of project proposals, the Committees will act in good faith and within the spirit of the collaborative nature of the HCPs to make project funding decisions and having a direct nexus to plan species, plan species habitat, or plan species management. Furthermore, consistent with Section 9 of the HCPs, voting members shall use their best efforts to exercise their rights and authority under statutes, regulations, and treaties, in a manner that allows the goals and objectives of the HCP Agreement to be fulfilled. Importantly, as agreed to during HCP negotiations, funding decisions require unanimous approval of the Committees (as described in HCPs Section 7), affording each member discretionary rights when reviewing and voting on project proposals.*

This is a brief summary of the events leading up to the disputed issue. The remainder of this document includes more specific information that may be useful in resolving the dispute. I include the letter from the Yakama Nation indicating their desire to dispute the decision by the HCP TCs to not support the SOA; the Yakama Nation Issue Statement; the draft SOA, which is the focus of the dispute; excerpts from HCP TCs final meeting notes (I only included sections of the final notes that are relevant to the disputed issue); and the evaluation criteria that the HCP TCs approved in April 2019.

I am available to answer any questions the HCP Coordinating Committees or HCP Policy Committees may have regarding the disputed issue.

Tracy W. Hillman, Ph.D.
HCP TCs Chair

2 Yakama Nation Letter to Initiate Dispute Resolution

On May 23, 2019, the Yakama Nation submitted a letter to the HCP TCs Chair indicating that they are formally disputing the decision by the HCP TCs regarding the draft SOA titled, *Basis for Decision Making in HCP Tributary Committees*. Below is the letter from the Yakama Nation initiating the dispute resolution process.

Date:	May 23, 2019
To:	Dr. Tracy Hillman, Chair Tributary Committee
cc:	Paul Ward, Manager, Yakama Nation Fisheries Lee Carlson, Tributary Committee Delegate Brandon Rogers, Tributary Committee Alternate
From:	Steve Parker, Technical Services Coordinator Yakama Nation Fisheries
Subject:	Tributary Committee dispute

The Yakama Nation herewith raises a dispute under Section 11 of the Rock Island HCP (and others by reference) regarding the project review procedures utilized by the Tributary Committee (TC) pursuant to Section 5 of *Tributary, Fund Policies and Procedures for Funding Projects, April 2017*. The dispute specifically concerns the rejection by the TC of a SOA offered at its April meeting which sought to affirm the scope of voting criteria given in Section 5 of the HCP. This action raises significant questions about the interpretation of voting criteria given in Section 5 that we feel need to be addressed outside of the TC membership. Bringing the issue through formal dispute resolution offers the best opportunity for a full exchange of views that we hope will lead to resolution.

Section 11.1.1 of the HCP is not entirely clear on the initial step of the dispute resolution process but it can be inferred that the Tributary Committee, presumably its Chair, submits the dispute to the Coordinating Committee for review. I request that you initiate that step upon receipt of this memo. To that end I have submitted an Issue Statement delineating the substance of the dispute that you are at liberty to distribute as appropriate.

Thank you for your assistance in advancing this matter.

3 Yakama Nation Issue Statement

Below is the Issue Statement, which attended the Initiation of Dispute Letter from the Yakama Nation.

ISSUE STATEMENT: Shall habitat project funding decisions by the Tributary Committee be required to demonstrate a nexus to Tributary Plan goals and objectives?

Background

The HCP Tributary Committee (TC) considered at its monthly December, 2018 meeting a funding proposal by the Yakama Nation to purchase a property in the Methow watershed for the purpose of fish habitat restoration. The TC members expressed support for the biological merit of the proposal but the representative for Colville Confederated Tribes indicated he was required by his policy leadership to reject any proposal by another tribe to acquire property in the Methow watershed. Operating procedures for the TC require consensus so funding for the proposed project was denied despite its biological merit.

Yakama Nation is appealing the decision on the basis that the CCT vote was politically-driven and unrelated to the voting criteria described in the TC operating procedures, *Policies and Procedures for Funding Projects*, *April 2017*. Section 5 of that document, entitled *Review Procedures*, states that, "The Committees will make funding decisions based on the above eligibility criteria, fund availability, and if necessary, the recommendations from technical advisors (discussed below). The Committees will use a more detailed review procedure for the General Salmon Habitat Program than for the Small Projects Program. *However, proposals to both programs will be evaluated for biological and technical merit, feasibility, durability, and cost-effectiveness.*" (emphasis added). While these voting criteria are general and allow broad discretion in the review of project proposals, they specifically do not include factors unrelated to the mitigation purpose of the Tributary Plan[5] or the TC's responsibility to implement it.[6] Yakama Nation proffered a SOA at the April TC meeting that would limit voting criteria to those explicitly described in Section 5 but the TC soundly rejected it.

Prospectus

The Yakama Nation is concerned that TC members apparently do not adhere to, by vote or action, the project review criteria agreed to in the HCPs and, hence, the FERC licenses. The converse of this failure to adhere to specific voting criteria is to conclude that the TC does not feel bound by *any* criteria in its project selection process. This is to say that any member can veto any project proposal for any reason without reason or recourse. The CCT vote is evidence of this and the TC's rejection of the SOA confirms it. To allow, and then endorse, voting criteria that lack any nexus to the mitigation purpose of the Tributary Plan risks the integrity of the Tributary Fund and the TC's fiduciary accountability for expenditures from it.

---

[5] Sec 7.2 of the HCP describes the purpose of the Tributary Plan as "compensating for two percent of Unavoidable Project Mortality."

[6] Sec 7.3.1 creates and charges the TC with the task of implementing the Tributary Plan.

Perceptions about the nature of this dispute vary widely but seem to be clouded by the inter-tribal aspect of it. To be clear, this issue is fundamentally not an inter-tribal dispute, it is a deficiency in TC voting procedures. Below we attempt to clarify some of the confusion and misunderstanding reflected in statements from some parties about the basis for this dispute:

- This is an inter-tribal dispute best left to the tribes to sort out. The substance of this dispute arose from policy interference by CCT in TC voting procedure, but it became a dispute only when the TC failed to invalidate policy interference as a basis for voting. The procedural issue is TC's willingness to allow irrelevant and extraneous voting criteria into the funding decision. Accordingly, any TC member now can veto any proposal by any entity for any reason without explanation or consequence. This is an egregious violation of the intent of the Tributary Plan and the written funding review procedures the TC must follow to implement it.
- Why not allow another entity to hold title to properties? This would address the substance of this dispute but would not resolve the underlying procedural problem that could produce future disputes if the TC does not clarify and abide by a set of voting criteria.
- The TC has been working well for 18 years and does not need to review voting procedures. The TC has worked well because the members adhered to criteria nominally compliant with policies and procedures in the guidance to the TC. The dispute arose only when that guidance was ignored for reasons unrelated to the mitigation purposes of the Tributary Fund.
- The TC does not want to lose flexibility and discretion in selecting projects for funding. The Yakama Nation has no interest in narrowing the latitude and discretion currently available to the TC in the existing five project selection criteria. However, we believe that any member's voting position must have at least a colorable nexus to the purpose and objectives of the Tributary Plan. It is not in any member's interest to accept voting criteria that have no relevance to implementing the Tributary Plan. To do so invites gaming, positioning, and leveraging to become part of funding decisions and potentially exposes the TC to criticism from an objective public reviewer.[7]

Proposed Settlement

The source of this dispute is relatively simple and its solution is equally simple. The Yakama Nation alleges that members of the TC voting on the basis of any factor not linked to the habitat restoration goals of the Tributary Plan violates the intent and specific terms of the funding review guidance by which the TC implements the plan. Accordingly, the solution is for TC members to clarify by SOA that valid voting criteria must have a demonstrable nexus to the mitigation purpose of the Tributary Plan and Fund. We are open to developing such language jointly to ensure that TC members' concerns are addressed in a way that still upholds the intent of the guidance given in *Policies and Procedures for Funding Projects*.

[7] Section 2 of *Policies and Procedures* states, "The Committees may hold annual public workshops to review its (sic) funding policies and procedures (Section 6.8)."

4 Yakama Nation Draft SOA

On February 25, 2019, the Yakama Nation submitted the following draft SOA for HCP TCs review and approval. On April 11, 2019, the HCP TCs voted on the SOA. All members except the Yakama Nation voted "no" on the SOA.

Rocky Reach, Rock Island, and Wells HCP Tributary Committees
DRAFT Statement of Agreement

Basis for Decision Making in HCP Tributary Committees
February 25, 2019

Statement

The Rocky Reach, Rock Island, and Wells Habitat Conservation Plans (HCP) Tributary Committees (TCs) agree that mitigation funding decisions will be based exclusively on the merit of proposed projects (biological benefit, technical merit, feasibility, durability, and cost effectiveness) having a direct nexus to plan species, plan species habitat, or plan species management. Signatories agree not to base funding decisions on criteria other than project merit.

Background

The Wells, Rocky Reach, and Rock Island HCP Tributary Committees' Policies and Procedures for Funding Projects (January 10, 2019) describes the eligibility and review criteria for evaluating project funding decisions. Section 5 of that document specifies that project funding decisions are made on the basis of biological benefit, technical merit, feasibility, durability, and cost effectiveness. However, Section 5 does not explicitly disallow criteria unrelated to resource benefits to be introduced into decision-making. The purpose of this SOA is to clarify that the Tributary Committees intend that all funding or other decisions regarding how PUD mitigation is implemented will have a direct nexus to the expected benefits to a plan species or plan species habitat. Decision making by a signatory for reasons unrelated to mitigation benefits are not within the spirit or intent of the HCPs and will impede the operation of the Committees. Any signatory attempting to vote on the basis of criteria other than those directly related to resource impacts may abstain from 'voting'.

5 Excerpts from HCP TCs Notes

This section includes excerpts from HCP TCs final meeting notes that are relevant to the dispute. Excerpts include HCP TCs discussions associated with the Scaffold Camp #2 Acquisition Project and the draft SOA. I included discussions associated with the Scaffold Camp #2 Acquisition Project because, in part, it precipitated the need for the draft SOA.

5.1 Excerpts from the December 2018 Notes

Scaffold Camp Acquisition #2 Project

The Committees received a General Salmon Habitat Program proposal from the Yakama Nation titled: *Scaffold Camp Acquisition #2 Project*. The purpose of the project is to acquire and protect a 1.3-acre parcel of floodplain/riparian habitat at RM 15.7 on the Twisp River. This project, along with the already protected 13-acre adjacent parcel, will not only protect high quality habitat, but it will allow the enhancement of a side channel, which would provide biological benefit for HCP Plan Species. The total cost of the project is $104,950. The sponsor requested $94,500 from HCP Plan Species Account Funds. The Tributary Committees elected not to fund this project.

On a technical level, the Committees support protecting the 1.3 acres of floodplain and riparian habitat along the Twisp River. On a policy level, however, this project was not supported by CCT and therefore HCP Plan Species Account funds cannot be used by YN to acquire the property. In an effort to avoid the possibility of the current landowner selling the 1.3-acre parcel to someone who is not interested in the conservation value of the property, the Committees recommend that YN discuss the acquisition of the parcel with other conservation-minded entities such as the Methow Salmon Recovery Foundation, Methow Conservancy, WDFW, or CCT. The Committees would be able to provide funding to one of these entities if the entity is willing to hold the fee title for the parcel and coordinate enhancement work on the property with YN.

Following the funding decision on the proposed project, Brandon Rogers indicated YN will dispute the Tributary Committees' decision and elevate this issue to the HCP Coordinating Committees and HCP Policy Committees. In order to avoid a dispute, members asked Brandon whether YN would be willing to ask another conservation group to hold the fee title for the parcel. Brandon indicated that YN wants to hold the fee title. Members asked Brandon whether the policy representatives from YN and CCT could discuss and resolve this issue without going through the "formal" dispute resolution process. Brandon indicated this will not happen. He said YN will dispute the decision based on principle.

Tracy Hillman reviewed the HCP dispute resolution process with the Tributary Committees. He asked Brandon to provide him with an official letter from YN. He said the letter should include a brief description of the issue under dispute (Scaffold Camp Acquisition proposal), the reason for the dispute, and the reason why YN is disputing the Tributary Committees' decision to not fund the project. Tracy said the letter will provide the basis for initiating the dispute resolution process. Tracy said he will contact Dr. John Ferguson, Chair of the HCP CC and HCP PC, and inform him of the likely dispute. Tracy also asked Tributary Committees members to contact their HCP CC and HCP PC representatives and let them know that they will likely be dealing with a dispute.

5.2 Excerpts from the March 2019 Notes

Review of the Yakama Nation Draft SOA

On 25 February, YN submitted a draft Statement of Agreement (SOA) to the Committees for review (see Attachment 1). Brandon Rogers said the purpose of the draft SOA is to provide a basis for decision making in the HCPs Tributary Committees. He indicated the SOA is draft and asked members to review and discuss it, edit it as necessary, and vote on it during the April meeting. Justin Yeager asked what precipitated the need for an SOA on decision making. Brandon responded the "NO" vote on the Scaffold Camp Acquisition #2 Project and the fact that the Committees have no clearly defined criteria for evaluating project proposals. Chris Fisher stated CCT cannot support the draft SOA nor will they support an SOA that will take away their right to prevent the YN from owning land in the Upper Columbia River basin. Jeremy Cram noted the language in the draft SOA is too strong and would force the Committees to vote "YES" on any project that has biological benefit. He said it appears to take way the Committees ability to require cost shares, to save money for future projects, and to reject projects based on a sponsor's ability to implement the project. He added it places too much emphasis on cost-benefit relationships. Others agreed and said it takes away rights to reject projects based on criteria that may not be included in the draft SOA.

Tom Kahler reminded members that funding decisions require unanimous approval of the Committees (as described in HCPs), affording each member discretionary rights when reviewing and voting on project proposals. Tom provided examples within other HCP committees where parties have exercised this right and stated that Douglas PUD could not approve any agreement that would limit those discretionary rights. Furthermore, editing the draft SOA to preserve the discretionary voting rights of signatory parties would result in a very complicated document that would no longer fulfill the intent of YN in preparing the SOA. Catherine Willard pointed members to Section 9.4 of the Rock Island HCP, which states voting members "shall use their best efforts to exercise their rights and authority under statutes, regulations, and treaties, in a manner that allows the goals and objectives of the HCP Agreement to be fulfilled."

Kate Terrell and Justin asked why an SOA is necessary. The Committees have made funding decisions and justified those decisions for several years. Brandon responded that without some side boards, the Committees can make decisions based on anything they want, and these decisions may have nothing to do with what is best for the resource. Catherine again reminded members of the language in the HCPs. Chris commented that except for the Scaffold Camp Acquisition Project (and a YN protection project that was submitted through the PRCC Habitat Subcommittee), he has always voted based on what he believes is best for the resource. He said he can do nothing about Tribal politics and the issues between CCT and YN cannot be resolved within the HCP Committees.

Kate asked, given that CCT cannot support an SOA that takes away their right to prevent the YN from owning land within the Methow River basin, what is YN trying to accomplish with the draft SOA? Brandon stated that the SOA is less about the issues between the tribes and more about how the Tributary Committees make funding decisions. To that end, YN wants clear, transparent criteria that focus funding decisions on what is best for the resource. Kate asked what if the SOA is not approved. Brandon said YN will consider disputing the decision and they are also evaluating other options.

Tracy Hillman reminded the Committees that they directed him to identify possible criteria for evaluating project proposals (see Attachment 2). He reviewed those criteria with the Committees and asked if these provide the clarity and transparency the Committees desire. He added that these could be appended to an SOA or added to the Committees' Policies and Procedures for Funding Projects document (Section 5). Tracy also noted that YN is not the only party who has requested evaluation criteria. Others have as well, and Tracy said the criteria will help him prepare responses to project sponsors. Members liked the idea of having transparent criteria and Kate noted that she used the criteria when evaluating the Eightmile Creek Fisheries Assessment Project. She said the criteria were very useful and were consistent with how she has evaluated projects in the past.

Members discussed the idea of updating Section 5 in the Policies and Procedures for Funding Projects. Some members believe this would eliminate the need for an SOA. Kate and Jeremy noted this would allow the Committees to review and update evaluation criteria annually or more frequently if necessary. Brandon said he will discuss this internally, but still wants the Committees to review and edit (if necessary) the draft SOA. He said the YN will ask for a vote on the draft SOA (or edited version) during the April meeting.

Members will review and edit, if necessary, the draft SOA and be prepared to discuss it and vote on it during the April meeting. In addition, Tracy will recast the evaluation criteria, so they fit within the Policies and Procedures for Funding Projects document.

5.3 Excerpts from the April 2019 Notes

Review of Yakama Nation Draft SOA

On 25 February, the Yakama Nation submitted a draft Statement of Agreement (SOA) to the Committees for review (see Attachment 2). During the March meeting of the Tributary Committees, Brandon Rogers said the purpose of the draft SOA is to provide a basis for decision making in the HCPs Tributary Committees. He indicated the SOA is draft and asked members to review and discuss it, edit it as necessary, and vote on it during the April meeting. Although members discussed the need (or no need) for an SOA during the March meeting, the Yakama Nation asked members to edit the draft SOA if necessary and be prepared to vote on it during the April meeting.

Tracy Hillman reported that he received no edits to the draft SOA. Therefore, he asked each member to vote on the draft SOA as written and provide their reasons for their yes or no vote. Members voted as follows:

- YN voted yes because there are no written rules for what criteria can and cannot be used to evaluate proposed projects. For example, a member can vote no on a proposed project based on criteria that have nothing to do with the project.
- NMFS voted no because they see no need for an SOA, and it does not address the issue between the tribes (between YN and CCT).
- CCT voted no because they cannot support an SOA that removes their right to prevent the Yakama Nation from owning property in the Upper Columbia.
- USFWS voted no because they see no need for an SOA. They believe the evaluation criteria developed for the Policies and Procedures document provide a sufficient foundation for evaluating project proposals.
- WDFW voted no because the SOA is too restrictive and other factors need to be evaluated in making funding decisions (e.g., competency of the project sponsor to implement the project, cost shares, etc.).

- CPUD voted no because they see no need for the SOA. They support the proposed evaluation criteria in the Policies and Procedures document.
- DPUD voted no because they see no need for the SOA and believe the evaluation criteria being developed are sufficient for evaluating proposed projects. In addition, they do not want members to lose their discretionary voting rights.

Tracy summarized the votes and reasons for the votes and asked the Yakama Nation if they intend to dispute the decision by the Tributary Committees. Brandon said they will discuss this internally and decide what they intend to do. Several members indicated that their organization's vote today will not change in the Coordinating Committee or Policy Committee. Thus, this issue is unlikely to be resolved in any of the HCP Committees. Tracy asked Brandon to let him (Tracy) know if the Yakama Nation needs guidance on initiating the dispute resolution process should they choose to dispute the Tributary Committees decision.

Chris Fisher reminded the group that except for the Scaffold Camp Acquisition #2 Project, the Committees have always made funding decisions based on the cost and biological merits of the proposed project. He said Tracy requires us to provide justification for our decisions. This gives Tracy and Becky the information they need to respond to project sponsor when sponsors question our funding decisions. Chris stated the issue with the Scaffold Project was a policy-level decision for which he had no control. He said policy-level intervention is not likely to change anytime soon.

Tracy thanked everyone for their candid and open discussion on the draft SOA.

6 Revised HCP TCs Evaluation Criteria

During the period when the HCP TCs were reviewing the Yakama Nation draft SOA, the HCP TCs were also reviewing and updating their criteria for evaluating restoration, protection, design, and assessment projects. Although the Yakama Nation SOA helped push the HCP TCs into updating their evaluation criteria, this was something the HCP TCs were considering before the review of the Yakama Nation SOA or the Scaffold Camp Acquisition #2 Project. Indeed, Chelan PUD asked the HCP TCs to provide more specific criteria for evaluating project proposals. The updated criteria are in Section 5 of the Tributary Committees Policies and Procedures for Funding Projects (April 12, 2019 version). For your convenience, I provided the updated and approved criteria below.

Review Procedures

The Committees will make funding decisions based on eligibility criteria (see Section 4), fund availability, and if necessary, the recommendations from technical advisors. During review of project proposals, the Committees will act in good faith and within the spirit of the collaborative nature of the HCPs to make project funding decisions and having a direct nexus to plan species, plan species habitat, or plan species management. Furthermore, consistent with Section 9 of the HCPs, voting members shall use their best efforts to exercise their rights and authority under statutes, regulations, and treaties, in a manner that allows the goals and objectives of the HCP Agreement to be fulfilled. Importantly, as agreed to during HCP negotiations, funding decisions require unanimous approval of the Committees (as described in HCPs Section 7), affording each member discretionary rights when reviewing and voting on project proposals.

Project proposals will be evaluated based on general and specific criteria. Below we identify the general criteria, which are from the HCPs, and specific criteria, which are based on biological and technical merit, feasibility, durability, and cost-effectiveness. The Committees may also solicit reviews of project proposals from technical experts outside the Committees.

Committees will make funding decisions based on the above eligibility criteria, fund availability, and if necessary, the recommendations from technical advisors (discussed below). The Committees will use a more detailed review procedure for the General Salmon Habitat Program than for the Small Projects Program. However, proposals to both programs will be evaluated for biological and technical merit, feasibility, durability, and cost-effectiveness.

General Criteria

Project proposals will first be evaluated based on the following general criteria.

Target Species
